THE ENGINEERING RECORD
ESTABLISHED 1877
BUILDING RECORD & THE SANITARY ENGINEER
A JOURNAL for the ENGINEER, ARCHITECT, CONTRACTOR, MECHANIC & MUNICIPAL OFFICER

PRIOR TO 1887, KNOWN AS THE SANITARY ENGINEER.

3761

CONDUCTED BY HENRY C. MEYER.

INDEX TO VOLUME XXII.

JUNE 7, TO NOVEMBER 29, 1890.

277 PEARL STREET, NEW YORK.

London Office, 92 and 93 Fleet Street.

ARCHITECTURAL ILLUSTRATIONS

PAGE

- "Aberdeen" Apartment House, St. Paul, Minn.. 388
- Allen & Kenway, architects, house at Wellesley, Mass ... 178
- Andrews, Jaques & Rantoul, architects, New Bedford, Mass., house... 242
- Athletic building, Cambridge, Mass. ... 99
- Babb, Cook & Willard, architects, New York Life Insurance Company's building, Montreal..... 226
- Boeswiwald, architect, Paris house... 210
- Boston, Mass., commercial building, 18; house.... 34
- Bridgeton, Me., house ... 67
- Brookline, Mass., house... 130
- Burgos, Spain, cathedral... 356
- Cambridge, Mass, athletic building ... 99
- Candelabra and fire dogs from South Kensington, Museum, London... 259
- Chateau d'Azay-le-Rideau, France ... 130
- Chateau du Moulin, France... 66
- Chateau du Fontaine, Hersey, France... 98
- Chestnut Hill, Pa., chapel ... 35
- Church, Pittsburg. Pa., 2; chapel, Chestnut Hill, Pa., 35; Clermont-Ferrand, France ... 50
- City stoop ... 211
- Clermont-Ferrand, France, church ... 50
- Depot, Wellesley Hills, Mass ... 3
- Dietrich, E. G. W., architect, house at Rutland, Vt... 51
- Doorway, Washington, D C... 83
- Emerson, W. R., architect, house at Boston..... 34
- Gateway in Holland ... 406
- Hapgood, E. T., architect, house at Orange, N. J. 147
- Hartwell & Richardson, architects, commercial building, Boston,... 18
- Hospital at Santa Cruz, Spain... 324
- Hotel Imperial, New York... 258
- House, Milton, Mass., 34; Rutland, Vt., 51; Bridgeton, Me., 67; Tuxedo Park, N. Y., 82; Massillon, O., 114; Waban, Mass ... 115
- House of Mary of Brava, Salamanca, Spain....... 340
- Iron work... 19
- Johnson, Lindley, architect, chapel at Chestnut Hill, Pa ... 35
- Johnson, C. H., architect, "Aberdeen" apartment house, St. Paul, Minn... 388
- Little, Arthur, architect, house at Swampscott, Mass., 146; house at Brookline, Mass. ... 130
- Longfellow, Alden & Harlow, architects, church at Pittsburg, Pa., 2: athletic building, Cambridge, Mass., 99; house at Portsmouth, N. H. 243
- Lord, J B., architect, house at Tuxedo Park, N.Y. 82
- Madison Square Garden ... 194
- Massillon, O, house ... 114
- McKim, Mead & White, architects, Hotel Imperial New York, 258; Madison Square Garden... 194
- New Bedford, Mass., house at... 242
- Newcomb, E. A. P., architect, residence of, at Boston... 179
- New York Life Insurance Co.'s building, Montreal, entrance to ... 226
- Orange, N. J., house at... 147
- Paris House... 210
- Pendleton, E H., cottage of, at Bar Harbor, Me. 293
- Pittsburg, Pa., church. ... 2
- Portsmouth, N. H., house... 243
- Preston, W. G., architect, house at Massillon, O.. 114
- Residence and stable, Boston, Mass... 372
- Richardson, H. H., architect, depot at Wellesley Hills, Mass. ... 3
- Robertson, R. H., architect, city stoop... 211
- Rotch & Tilden, architects, Bar Harbor cottage... 293
- Rutland, Vt., house ... 51
- Shepley, Rutan & Coolidge, architects, residence and stable, Boston, Mass.... 372
- Shooting lodge of Francis I., Paris ... 274
- Stackpole's, Dr. F. D., residence at York Harbor 163
- Stevens & Cobb, architects, house at Bridgeton, Me 67
- Swampscott, Mass., house at... 146
- Tuxedo Park, N. Y., house. ... 82
- Viaduct in Spain.. ... 325
- Waban, Mass, house ... 115, 195
- Warren, H. L., house at Waban, Mass...... 115, 105
- Washington, D. C., doorway of Purdy house. ... 83
- Waterloo Hotel, North Wales ... 162
- Wellesley Hills, Mass., depot... 3
- Wellesley, Mass., house... 178
- West Front, Church Echillais, France... 292
- Wheelwright & Haven, architects, residence at York Harbor... 163
- Williams, John, blacksmith, wrought iron work... 19

GENERAL SUBJECTS.

A

- Abbott, F. G., personal... 388
- Abel, Sir Frederick, personal... 274
- Ackenheil, C., obituary ... 50
- Acton, E. L., personal... 34
- Adams, William H., obituary... 146
- Adamson, J C., on water supply of buildings.... 123
- Adler & Sullivan, office... 5
- Air, safeguard for workers in compressed, 2; compressed for working elevators, 24; compressed for sanitary purposes, 380; determining change of, 134; filtering, 66; fresh, inlet, 138, in water, 122; moistener, Dimmick, 236; vessels on pipes and pumps... 230
- Alby, A. E., personal... 114
- Algæ growths in wells ... 202
- Allen, Charles A., personal... 210
- Allen, H. C., personal.. ... 292
- Allen, Martin, obituary... 292
- Alleyne, Sir J. G., personal... 275
- Alum action on microbes in water... 377
- American Boiler Makers' Association, meeting... 66
- American machinery abroad... 162
- American Public Health Association meeting at Charleston... 82
- American Railway Master Mechanics' Association, action as to technical schools... 66
- Ammonia refrigeration ... 61
- Amweg, F. J. personal... 340
- Anchoring bolts, adhesive strength of sulphur, lead and Portland cement for... 201
- Andrews, F. H., obituary... 50
- Andrews, J. P., obituary ... 456
- *Annales des Ponts et Chaussees*... 104
- Appleton, G. S., letter from ... 124
- Aqueduct, Croton, 258; plate girder... 260
- Archer, J. W., letter from... 61
- Architects, a lesson for, 209; expert advice for, 225, 233
- Architects' and engineers' convention in Hamburg 51
- Architects' offices, Samuel Hannaford & Sons, Cincinnati, 180; Adler & Sullivan, Chicago... 5
- Architectural Societies:
  - American Institute of Architects, Philadelphia chapter of... 309
  - Washington meeting... 308, 341
- American Institute of Building Arts... 180
- Architectural League of New York... 274
- Cincinnati Architectural Club, exhibition drawings and sketches ... 28
- Architecture and Democracy, Peabody on... 51
- Arch work in earthquake countries... 146
- Arizona water storage... 166
- Armstrong, C. R., obituary... 66
- Arrol, Sir Wm., personal... 242
- Artesian wells in water works. ... 7
- Asbestos, uses of... 237
- Asphalt floor... 6
- Association of Steam Radiator Manufacturers' meeting... 18
- Atkinson, O. W., obituary. ... 194
- Auckland, N. Z., calliope dry dock... 389
- Aulls, M., personal ... 308
- Austin, Tex., water power. ... 344
- Avery architectural library... 99
- Avon, Mass., water works ... 26

B

- Babbitt, H. C., personal. ... 50
- Bacot, W. S., personal... 18, 98
- Baguley's pipe stopper... 13
- Baker, Benj, personal ... 226, 242
- Balbach, Sr., Edward, obituary... 308
- Bamboo, growth of... 182
- Barber, Sam., obituary. ... 406
- Barrett storage battery... 362
- Barrie, Ont., water works and sewerage system... 5
- Batchelder, R. N., personal ... 50
- Bates, Onward, personal... 130
- Baths, public, New Orleans, 2; Wilmington, Del., 18; New York... 44, 201
- Bayles, J. C., letter on steel for water and other pipes, 185; personal ... 34
- Beach, J. W., personal... 340
- Beahan, Willard, personal ... 130
- Beam bracket on cast iron column... 42
- Befreus, M. S, personal,... 340
- Berlin, filtering sewage, 122; sewage, 315; telephones, 45; electrical works... 276
- Billings, Frederick, obituary ... 274
- Billings, Dr. J. S., personal... 104
- Billings, W. R., furnace ... 122
- Birmingham ship canal. ... 310
- Blasting large masses of iron and steel. ... 134
- Blowers and exhaust fans. ... 45
- Blunt, W. T., personal... 50
- Bogart, J., personal... 114, 274
- Book notices, 152, 188, 217, 233, 249, 266, 284, 293, 334, 366... 383
- Books received, 13, 42, 61, 78, 106, 130, 146, 201, 237... 324
- Books on building wanted, 138; on flumes... 234
- Boiler: See water-works and plumbing. Care of, 113; hot-water, 124; unequal temperature of water in, 146; data on settling, 152; flexible stays, 202; Star water tube, 202; effect of tube length on evaporative power, 202; dynamo for preventing incrustation and corrosion, 220; connections for rotary, 364; automatic water feeder for, 534; feeding when short of water.. 382
- Bonticou, D., personal... 114
- Boreholes, deep... 172
- Borland, C. W., personal... 50
- Boston, Mass.: Marine park, 8; rapid transit schemes, 18; plumbing law, 43; inspection of electric wires ... 413
- Boston Heating Company, suits against... 340
- Boynton, Dr. J. F., obituary ... 324
- Brackett, D., on water delivery from service pipes 84
- Brewery design and construction, books on... 266
- Brick: famine, 148; boycott, 193; paving, 204; and tile making in the 13th century, 215; pavements in Holland, 237; zinc in contact with, 311; from waste of plate glass manufactories, 408; making at Bagdad ... 414
- Bridge: See Brooklyn Bridge. Selby Avenue, Minneapolis, floor, 6; new method of investigating stresses, 8; astonishing detail at Newark, England, 8; large in India, 9; facts about wanted, 18; "Greene" Hudson River, 18; poor highway at Syracuse, N. Y., 40; deflections of Sher Shah, 55; Hudson River, 66, 233, 268; endurance of iron in, 72; over Duluth ship canal, 117; upheaval of foundations in Holland, 117; foot, in India, 120; inspection in Austria, 137; erector's hydraulic jack, 137; Wheeling viaduct, 148; rustic, Burmah, 167; floating Ohio connecting railroad, 178; recent construction in railroad, 182; launching Forth Bridge caissons, 213; floating the Ohio connecting railway channel span, 226; the Dalmarnock, Glasgow, 245; French testing device, 246; cost of repair of pile, 248; a concrete, 262; erection of Hooghly, India, 277, 328; Thames River, 295, 310; Philadelphia specifications, 311; Carl's, at Prague, 330; building over navigable waters, 372; design and factors of safety ... 380
- Bridgeport, Conn., macadam roads... 50
- Brigham & Spofford, personal ... 2
- Brinckerhoff, H. W., personal... 210
- Bromley, Wm., personal... 388
- Brooklyn, N. Y: Greene avenue relief sewer, 407, bridge commission meeting, 100, improving bridge, 114; bridge traffic... 169
- Brooks, F., on French forestry... 9
- Brown, D. W., personal... 356
- Brush, W. B., personal... 34
- Butler, W. P., personal ... 226
- Bucholz, C. W., personal ... 34
- Builders' and Contractors' Engineering and Plant:
  - Reinforcing an iron floor... 74
  - Repairing church roof truss... 86
  - Ropes and hitches... 105
  - Raising and moving a brick furnace... 136
  - Launching 70-foot Forth bridge caissons.... 213
  - Erection of Hooghly jubilee bridge, India, Part I, 277; Part II... 328
  - Walditobel arch centering ... 344
  - Three-ton hand derrick crane on Forth bridge, 344; Chicago elevated railroad erection, 362; underpinning Yarmouth city hall.. 379
- Building: Yonkers law, 12; national convention of inspectors, 13; slow burning wood forts, 19; iron window frames and doors, 27; mill construction, 39; in earthquake countries, 105; ventilating theater, 108; Western Union fire, 113, 114; slow burning, one story, 133; waste as material, 134; fireproof, 145, 148; lesson for departments, 177, 178; inspection in Brooklyn,

PAGE

- 185; inspection, 217; irrational plans, 241; slow burning construction, 330; New York *World* ... 342, 358, 374
- Buchanan, W., obituary ... 18
- Building Construction Details:
  - Chicago auditorium roof trusses ... 394
  - Hinged ceilings in Chicago auditorium ... 409
- Bullard, P. C., obituary ... 340
- Burmah, rustic bridge ... 167
- Burmese oil wells ... 146
- Burnett, G. R., personal ... 146
- Burson, W. B., personal ... 258

C

- Cable propulsion ... 124
- Cable railroad. See Railroad.
- Calliope dry dock at Auckland, N. Z. ... 389
- Camden, N. J., report on streets and highways ... 252
- Cameron, Alex., obituary ... 146
- Canal, Maryland and Delaware ship, 2; Suez, 4; in Germany, 4; Chesapeake and Ohio, 18; work on Nicaragua, 18, 201, 233; Manchester ship hospitals, 41; publication on construction of locks and gates, 90; Paris ship, 98; projects, in France, 179; Ocmulgee, 180; Panama, 185; tapping the Erie, 201; a remarkable, 343; Panama, 356; Hennepin, 357; Onega White Sea ... 378
- Candle power of electric lights ... 250
- Cannon, H. W., personal ... 274
- Car, coal for water works use ... 85
- Carpenter, R. C., personal ... 50
- Casey, W. W., personal ... 274
- Ceilings blackened ... 182
- Cement See Mortar. Magnesia in Portland, 378; nomenclature of, 346; at Stettin, Germany, 308; specifications for Portland, 21; slag, 197; tests in France, 130; influence of sea water on Portland ... 216
- Cesspool, death in a ... 236
- Chadwick, E., obituary ... 82
- Chain hauling, electric in coal mines ... 117
- Chesapeake and Ohio Canal ... 18, 162
- Chicago, Ill., tall tower, 4; World's Fair, 17; drainage law upheld, 18; heating ordinance, 27; water works crib, 90, 100, 122; fair site, 115; smoke trouble, 241; Drainage Board and Engineer Cooley, 265; elevated railroad, 362; auditorium roof trusses, 394; auditorium, hinged ceilings, 409; underground electric cables, 389; politics in Drainage Commission .. 405
- Childs, G. W., recollections of Gen. Grant ... 82
- Chimney, height of factory, 65; iron in London, 50; wrought iron, 120; efficiency of factory, 182; peculiar wrought iron ... 120
- Church, structures, early ... 169
- Church, B. S., personal ... 162
- Cincinnati, O., water works controversy, 81; water works report, 1889, 166; history of water works, 357; manual training school ... 196
- Cistern, largest in the world ... 155
- Cities, planning of early ... 121
- "City of Paris," accident to ... 52
- Clarke, C. M., obituary ... 34
- Clarke, T. C., personal ... 34
- Clerk of Works ... 339
- Cleveland, O., water works crib ... 100
- Clonmel, Ireland, water works and sewerage. ... 284
- Cloud, H. H., personal ... 98
- Coils, cost of 1-inch branch tee ... 155
- Columbia College, 18; Avery architectural library, 99; architectural fellowship ... 2
- Compressed air. See Air.
- Concrete houses in India. ... 276
- Consumption, relations of to width of streets ... 291
- Conventions, engineers' ... 65
- Cooley and the Chicago Drainage Board ... 265
- Cooper, F. H., obituary ... 340
- Cooper, G. F., letter from ... 122
- Corinth Canal ... 390
- Cornell, O. H. P., personal ... 210
- Cornell University, degrees conferred, 34; course in architecture, 84; water works ... 376
- Corrosion of iron beams from cinder filling ... 418
- Cramer, L. H., personal ... 18
- Crane, three ton hand, on Forth Bridge ... 344
- Cranes, electric power for ... 19
- Cremation. See Garbage.
- Creosoting wood ... 195
- Crittenden, W. L., obituary ... 2
- Croton Aqueduct, 131, 258; completing, 2; contractor's claims, 17; water let in, 35; water turned in, 82; opening, 98; repairing new, 163; excavation of ... 280
- Croton dam, new ... 312
- Crowell, Y. F., personal ... 308
- Currents, Lake Erie ... 21, 73
- Cutting, A. G., personal ... 274
- Cuyler, J. G., personal ... 50

D

- Dam, Vyrnwy (Liverpool) ... 89
- Darling, E., on efficiency of hydrants ... 4
- Dougherty, S. N., personal ... 2
- Davenport, Iowa, water works ... 5
- Davis, E. C., personal ... 34
- Davis, E. S., personal ... 2
- Davis, Joseph, obituary ... 340
- Davison, H. J., obituary ... 114
- Dayton, O., water works report ... 42
- De Kinder, J. J., personal ... 34
- Delta metal ... 300
- Denver, Col., water works, 24; cleaning reservoir. 56
- Detroit, Mich., water meters at, 162; pavement and sewer work ... 268
- Diamond drill practice ... 281
- Dickerson, W. A., personal ... 210
- Dimmick air moistener ... 236
- Disinfection: Apparatus in the Louisiana Quarantine Station, 101; of excrementitious substances, 132; candles for ... 178
- District of Columbia, sewerage ... 393

SECOND EDITION.

STEAM-HEATING PROBLEMS;

OR,

QUESTIONS, ANSWERS AND DESCRIPTIONS RELATING TO STEAM-HEATING AND STEAM-FITTING FROM "THE SANITARY ENGINEER."

PRESS COMMENTS.

"This is a most practical and useful work for the engineer and mechanic in the lines of work which it covers. * * * It contains information that every man who builds a house and contemplates heating it by modern methods should know. The contents of the book embrace papers on steam boilers, the value of heating surfaces, radiators, and heaters, piping and fitting, ventilation, steam, cutting nipples and bending pipes, raising water automatically, moisture on walls, etc., and a number of miscellaneous topics and questions, all of great interest Clearly and ably printed."—*Boston Herald*

"Fills a want, and fills it well. * * * No other treatise on steam-heating gives reply to and quotes experience relating to so many puzzles which the steam-engineer and steam-fitter are at times confronted with in practice."—*Buildin* .

"It would be difficult to find in any language a work more comprehensive than this, which will be found to answer almost every question concerning steam-heating that might occur to the non-professional or professional."—*Memphis Appeal*

——*With One Hundred and Nine Illustrations.*——

Large 8vo. Handsomely bound. Sent post paid on receipt of price, $3.00

ADDRESS, BOOK DEPARTMENT,

(Prior to 1887, THE SANITARY ENGINEER.)

THE PRINCIPLES OF

Ventilation and Heating

AND THEIR PRACTICAL APPLICATION.

By JOHN S. BILLINGS, M. D., LL.D. (Edinb.) Surgeon U. S. Army.

PROFUSELY ILLUSTRATED.

SECOND EDITION

(With Corrections, November, 1886.)

TABLE OF CONTENTS.

Expense of Ventilation—Difference Between "Perfect" and Ordinary Ventilation—Relations of Carbonic Acid to the Subject—Methods of Testing Ventilation.

Heat, and some of the Laws which Govern its Production and Communication—Movements of Heated Air—Movements of Air in Flues—Shapes and Sizes of Flues and Chimneys.

Amount of Air-Supply Required—Cubic Space.

Methods of Heating: Stoves, Furnaces, Fire-Places, Steam, and Hot Water.

Scheduling for Ventilation Plans—Position of Flues and Registers—Means of Removing Dust—Moisture, and Plans for Supplying It.

Patent Systems of Ventilation and Heating—The Ruttan System—Fire-Places—Stoves.

Chimney-Caps—Ventilators—Cowls—Syphons—Forms of Inlets.

Ventilation of Halls of Audience—Fifth Avenue Presbyterian Church—The Houses of Parliament—The Hall of the House of Representatives.

Theatres—The Grand Opera-House at Vienna—The Opera-House at Frankfort-on-the-Main—The Metropolitan Opera-House, New York—The Madison Square Theatre, New York—The Criterion Theatre, London—The Academy of Music, Baltimore.

Schools.

Ventilation of Hospitals—St. Petersburgh Hospital—Hospitals for Contagious Diseases—The Barnes Hospital—The New York Hospital—The Johns Hopkins Hospital.

Forced Ventilation—Aspirating-Shafts—Gas-Jets—Steam Heat for Aspiration—Prof. Trowbridge's Formulæ—Application in the Library Building of Columbia College—Ventilating-Fans—Mixing-Valves.

Large 8vo. Handsomely Bound in Cloth. Price $3.00. Postage paid.

ADDRESS, BOOK DEPARTMENT,

THE ENGINEERING RECORD,

277 PEARL STREET, NEW YORK.

(Prior to 1887, THE SANITARY ENGINEER.)

Some Details of Water-Works Construction.

By W. R. BILLINGS, Superintendent of Water-Works at Taunton, Mass.

WITH ILLUSTRATIONS FROM SKETCHES BY THE AUTHOR.

INTRODUCTORY NOTE.

Some questions addressed to the Editor of *The Engineering Record* by persons in the employ of new water-works indicated that a short series of practical articles on the Details of Constructing a Water-Works Plant would be of value; and, at the suggestion of the Editor, the preparation of these papers was undertaken for the columns of that journal. The task has been an easy and agreeable one, and now, in a more convenient form than is afforded by the columns of the paper, these notes of actual experience are offered to the water-works fraternity, with the belief that they may be of assistance to beginners and of some interest to all.

Sent, post paid, on receipt of $2.00. *HANDSOMELY BOUND IN CLOTH.*

Plumbing and House-Drainage Problems;

OR,

Questions, Answers and Descriptions from THE SANITARY ENGINEER.

OPINIONS OF THE PRESS.

"This volume contains replies to a very great variety of questions, all accompanied by cuts, some of them showing the errors which have been committed in work actually done, and others showing how it should be done. In the columns of the periodical this important advice was scattered through many numbers, and hence difficult of access. * * * In this book it is brought compactly together, classified as far as practical, and so placed within easy reach of every man and woman who has occasion to build a house, or who cares to know something of what the plumbing should be in selecting a house for rent. Few people ever think of such things in selecting houses, and the result is an unfailing crop of diphtherias, etc., etc. A cursory glance through this volume will satisfy any thinking reader that it is valuable for anybody to have conveniently at hand for reference."—*Chicago Times.*

"'Plumbing and House-Drainage Problems' is a work which should interest a large class outside of the plumbers' trade or profession of sanitary engineers. The book finds its origin in replies of THE SANITARY ENGINEER, an acknowledged authority in such matters, to questions covering innumerable phases of the subjects of water-supply, sewerage, sewage disposal, ventilation, hot-water supply and circulation, heating, lighting, house-drainage, and plumbing. It constitutes, therefore, a sort of cyclopædia of information upon these subjects, in regard to which the public cannot afford to be in ignorance. A carefully prepared list of contents arranged under the various headings and an alphabetical index make reference easy to any particular matter treated of.' The work contains upward of 250 pages, is illustrated by 142 engravings, and is neatly printed and bound in cloth."—*American Artisan*

With 142 *Illustrations. Large* 8*vo., Cloth*, $2.

HOT-WATER HEATING AND FITTING.

BY

William J. Baldwin, M. E.

A TREATISE on the practice of warming by HOT-WATER, with modern methods, discribed and explained.

The book containes much of the matter on this subject which has appeared in the columns of THE ENGINEERING RECORD, together with a large amount of additional original data.

The volume is a large 8vo. handsomely bound in cloth and fully illustrated, 392 pp.

Among the questions treated are the following:

The cause of the circulation of the water within heating-apparatus.
Motion explained by the use of diagrams.
How to find the velocity of the flow of water in pipes of an apparatus.
Simple formulæ explaining the laws which govern the flow of water in an apparatus.
Diagrams showing the co-efficients of the curve of the expansion of the water.
Diagram showing the velocity of water in feet per second when the height from which it flows is known.
The use of the diagrams in estimating the flow of the water through the apparatus.
Table of the quantity of water in U. S. gallons of the water that will pass through pipes of a given diameter.
Table giving the friction loss in inches of the water head for each ten feet of length of different sizes of clean iron pipes discharging given quantities of water per minute.
The loss of head by friction and resistance of elbows.
Saving by long radius elbows.
Saving by smooth elbows.
Resistance caused to the flow of water by elbows and return bends.
Resistance caused by valves, etc., and how it may be made less.
How to find the flow of water through main pipes of an apparatus
To find the quantity of water that will pass in U. S. gallons when the total head is known.
To find the diameter of a pipe for a given discharge of water.
To find the discharge of pipes for given diameters.
How to compute radiating surfaces.
Experiments of Tredgold and Hood in warming surface.
Experiments of modern investigators on radiators
How to find the amount of water that should pass through a radiator to do certain duty.
How to determine the size of inlet and outlet to hot-water radiators.
How to estimate the quantity of water that should pass through a radiator for a loss of 10 degrees.
Diagram giving the diameter of flow and return pipes when the radiating surface and the length of the pipes are known.
Experiments illustrating use of diagram in the piping of buildings.
The different systems of mains used in hot-water heating.
Treatment of single circuits.
Branch circuits.
Compound circuits.
How to proportion the apparatus for indirect heating.
Heat given off per square foot of surface.
Loss of heat through walls and windows of a room.
Heat lost by ventilation—how to consider it.
How to find heating surface of a room warmed by indirect radiation.
Comparative experiments with hot-water coils.
Diagram of sizes of main pipes for indirect radiation.
Examples of buildings warmed by hot water.
Boilers used in hot-water apparatus.
Direct and indirect radiators used in hot-water apparatus.
Expansion tanks and how they should be used.
Special fittings for hot-water apparatus.
How to conduct experiments in testing the efficiency of hot-water radiators.
How to control fires by the heat of water.

The whole containing a large amount of practical and useful information of great value to the Engineer, Architect, Mechanic and Householder.

Sent (post-paid) on receipt of $4.00.

ADDRESS, BOOK DEPARTMENT,

THE ENGINEERING RECORD,

(Prior to 1887, THE SANITARY ENGINEER.)

277 PEARL STREET, NEW YORK.

8vo. Cloth, 410 pp. **Price $5.00.**

PAVEMENTS AND ROADS;

THEIR

CONSTRUCTION AND MAINTENANCE.

REPRINTED FROM

THE ENGINEERING RECORD,

COMPILED BY E. G. LOVE, PH. D.

PREFACE.

THIS book is a compilation of articles which have appeared in recent volumes of THE ENGINEERING RECORD, edited with a view of eliminating whatever was of timely or local interest, and arranged by divisions for convenience of use.

The science of paving and the need of proper maintenance of pavements is yet comparatively little understood in this country, and the same is true in even greater degree with regard to roads. The editor of the journal named was led to give the matter special attention by seeing what was done in Europe, during his visits there, and finally began an investigation of work on streets and roads in England, France and other countries, the result of which was the gathering of a large and very valuable mass of information in regard to the subject. Of this everything likely to be of practical use in America was printed in THE ENGINEERING RECORD, and is given here in more convenient shape. With it appears a large quantity of matter from American sources, including the prize essays on Road Construction and Maintenance submitted in the competition instituted by the journal named in December, 1889.

It will be seen that the great bulk of the book is made up of records of experience and statements of cost in different places. The comments are based on this experience.

TABLE OF CONTENTS.

PART I.

CHAPTER I.—STONE PAVEMENTS.

Construction of, in Liverpool—Paving Inspection—Specifications in New York—Violation of Specifications—Paving Material.

CHAPTER II.—WOOD PAVEMENTS.

Construction of, in London—Cost and Durability—Specifications for Materials—Wood Pavements in Paris and other Cities—Sanitary Aspects—Necessity of Maintenance.

CHAPTER III.—ASPHALT PAVEMENTS.

Nature and Uses of Asphalt—Pavements in the United States, Paris and Berlin—Cost and Maintenance of in London and Liverpool—Renewals—Injury by Gas—Slipperiness—Affecting the Value of Property.

CHAPTER IV.—BRICK PAVEMENTS.

Clays, and the Manufacture of Paving Brick—Crushing Strength—Use in American Cities—Construction and Durability—Specifications—Miscellaneous Road Metaling Material.

CHAPTER V.—CURBS, SIDEWALKS AND TRAMWAYS.

Artificial Stone for Curbs—Footpaths in England—Asphalt and Concrete for Footpaths—Liverpool Tramways.

CHAPTER VI.—STREET OPENING—MAINTENANCE.

Liverpool Excavation Contract—Opening and Reinstating Pavements—Requirements in New York—Maintenance of Pavements in London—Cleaning London Pavements.

CHAPTER VII.—NOTES.

Experience with Various Pavements in London—Traffic in Paris and in American Cities—Iron Wheelways—Effect on Health of Noisy Pavements—Tests of Durability—Contracts Guaranteed.

PART II.

ROADS: CONSTRUCTION AND MAINTENANCE.

Repair and Maintenance—Common Roads in France—Road Making—Improving Country Roads—Specifications—Legislation—Macadam Roads—Herschell's Treatise on Road Making—Methods of Superintending Construction and Repairs.

PART III.

PRIZE ESSAYS ON ROAD CONSTRUCTION AND MAINTENANCE. submitted in the Competition instituted by *The Engineering and Building Record.*

Report of Committee of Award.

Abstracts of Essays receiving Honorable Mention.

A Plea for Æsthetic Considerations in Road Making.

Comments on the Prize Essays by the Committee of Award.

Sent Post-paid on receipt of Price.

ADDRESS, BOOK DEPARTMENT.

THE ENGINEERING RECORD,

277 PEARL STREET, NEW YORK.

(Prior to 1887, THE SANITARY ENGINEER.)

Obtainable at London Office, 92 and 93 Fleet Street, London, Eng., for 25*s*.

SOME PRESS COMMENTS.

The literature of road making is surprisingly small, and this is partly the consequence and partly the cause of the gross ignorance generally shown in all parts of this country by those who have charge of the expenditure of public money for road building and repairs. The study of the science of road making has not been especially attractive to engineers, for the reason that the rewards are small and not comparable, either in amount or in duration of employment, with those to be received in other branches of engineering. The editor of THE ENGINEERING RECORD has assiduously cultivated the few * * * members of the profession who have made unbiassed and thorough studies of economical pavement and road construction, and drawn from them for publication in his journal the best results of their experiences. The volume which he has had compiled from the series of papers and discussions evoked, contains over 400 octavo pages of the most essential and profitable information on the subject at present available.—*Railroad Gazette, June* 6, 1890.

A most creditable and seasonable compilation. It is decidedly the best collection of data on this important subject that has yet appeared in book form.—*Engineering News, June* 21, 1890.

* * * It should have a place, especially in the offices of street and county commissioners, where its suggestions might soon contribute greatly to the commercial welfare, safety and convenience of thousands of communities in our land.—*Iron Age, June* 19, 1890.

The art of road making is very imperfectly understood. There is little improvement from costly experience in most parts of our country. Experiments tried in one city are repeated in others for the benefit of contractors and holders of patents—who ascribe failures to local conditions. The streets of our cities are continually torn up to try some new kind of pavement or manner of using materials on hand. Traffic upsets all the calculations of engineers, and makes havoc with roads which are fit only for pleasure drives. A great want evokes many expedients and inventions. This book gives a record of the more important ones and comments on the trials made, more or less extended and successful.—*Metal Worker June* 21, 1890.

The book contains a large amount of valuable information collected from various sources, including records of experience with pavements of various kinds, methods of construction and maintenance adopted in this country and in Europe, and other matter of a similar kind; most of it practical and easy of application. Is is on a subject upon which information is much needed, and which has been too generally neglected in this country, and the book is therefore likely to be of much service to engineers. * * * This treatise is the first American work on the subject which has appeared in a considerable time. * * * It is well worth a careful reading by all who are interested in the subject.—*Railroad and Engineering Journal, July*, 1890.

That excellent technical journal, the ENGINEERING RECORD (New York), has for several years been publishing special articles and information from every available source concerning road making. The publishers have now issued a volume compiled from those articles with the title, "*Pavements and Roads; their Construction and Maintenance*," the compilation being done by E. G. Love, Ph. D. Matter of merely temporary or local interest has been eliminated and the remainder arranged by divisions for convenience of use. The result is a portly volume, packed closely with practical information concerning paving and road making in the Old World and the New, the great bulk of the book being made up of records of experience and statements of cost in different places with comments based on this experience. The work is a whole library on this special subject and its practical value is self-evident.—*Cleveland Plain Dealer, June* 8, 1890.

WATER-WASTE PREVENTION: Its importance and the evils due to its neglect. By HENRY C. MEYER, Editor of THE ENGINEERING RECORD.

(From the Preface.)

"If the publication of this little book increases the popular appreciation of an urgent public necessity, and tends to secure for water-works officials who are striving to do their duty in the matter of restricting the waste of water the support of influential members of their community, the author will feel amply repaid for the labor involved in gathering and presenting this information"

Price $1.00, *Sent post-paid on receipt of price.*

ADDRESS, BOOK DEPARTMENT.

277 PEARL STREET, NEW YORK.

Obtainable at London Office, 92 and 93 Fleet Street, for 5*s*.

ELEVENTH EDITION.

STEAM-HEATING FOR BUILDINGS, by William J. Baldwin, is a book for architects and steam-fitters. It informs the former on technical information in a branch of buildings not well understood by the professional man, and gives simple rules for the guidance of the practical man.

By it can be found:
(1) The size radiators to use;
(2) The size of main-pipes and returns;
(3) The boiler surface for any building
(4) The class of boiler to use;
(5) How to set a boiler;
(6) Grate surface for a boiler;
(7) Safety-valves for boilers and their size;
(8) Draught-regulators and how to set them;
(9) Water-feeders;
(10) Air-valves, and where to apply them;
(11) Useful information about iron pipe;
(12) The philosophy of steam.

Price $2.50.

ADDRESS, BOOK DEPARTMENT.
THE ENGINEERING RECORD,
277 PEARL STREET, NEW YORK.

Office Building Construction.

THE four numbers of THE ENGINEERING RECORD containing a full illustrated description of the great Drexel Office Building in Philadelphia, of which Wilson Brothers & Co. were the architects, have been bound together and are offered for sale

The articles give detailed descriptions of the construction and have a large number of illustrations, including 2 general sections and 6 floor plans; 16 general and detail illustrations of the foundations, piers and footing reinforcement; numerous details of the columns and floor beam connections; 10 illustrations of the great pilasters; complete details of the iron truss that carries the upper eight stories over the Stock Exchange Hall, which is thus given a large floor unincumbered by columns; and details of the electric light and telephone conduits. There is an explanation of the mechanical plant and systems—viz.: boilers and water supply, heating and ventilating, and lighting.

Price, paper cover, post paid, 60 *cents.*

Subscription, 20s. per annum in advance, post paid. IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.

20*s*. in GREAT BRITAIN. Other Foreign Countries $5.
Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $5; China, Japan, Sandwich Islands, Mexico and Cuba, $5; South America, $5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

ELEVATED SIDEWALKS FOR NEW YORK.

LAST Sunday's issue of the New York *World* contains on its first page a cheerful picture, entitled "Looking Forward," which purports to be "a prophetic photograph of one of New York's busiest streets as it ought to appear before many years," and shows Broadway at Park Place, both streets being provided with elevated sidewalks on which crowds of happy pedestrians are serenely promenading, while below, as now, "the chariots rage in the streets and jostle one another in the broad ways," but with this difference, that there are no luckless wayfarers for them to molest or make afraid.

The beauty of this scene is enhanced by contrast with the visions of accident and sudden death which fill nearly a page of the inside of the paper and which are well calculated to convey the impression that the life of the average New York pedestrian is somewhat more dangerous than that of a railroad brakeman. Unfortunately these pictures do not exaggerate the conditions too often prevailing in the streets of the metropolis, for which no remedy but the elevated sidewalk seems to be practicable, and from many interviews published in the *World* the idea of such a remedy seems, as a rule, to be favorably received by all classes.

The people of New York are to be congratulated that such an important improvement has received the support of one of their leading dailies, and it is interesting now that the idea has been brought so prominently forward to trace its first beginnings, which, as might be expected, are to be found in the technical press.

Not to go back to the short lived Lowe Bridge over Broadway and Fulton Street, which seems to have been born out of due time, and to have produced little impression even as a precedent, the first published suggestion of street bridges in New York, apart from those connected with the elevated roads, seems to be found in the description of the new ferry house at Barclay Street, published in THE ENGINEERING AND BUILDING RECORD of November 24, 1888. The designers of this building, Messrs. Cooper & Namur, made provision for the future use of double deck ferry-boats and a foot bridge across West Street, so that passengers could pass from the upper deck of the ferry-boat to the east side of that crowded thoroughfare. This, however, only looked to a street crossing, but the complete idea of an elevated sidewalk was brought out in an editorial in this journal in November 23, 1889, where, in commenting on the offer of the Pennsylvania Railroad Company to build a bridge across West Street from its Cortlandt Street ferry house, it was suggested that it "should be supplemented by an elevated sidewalk continued up the streets towards Broadway to the elevated depots."

These West Street foot bridges were further and favorably commented on in this journal on February 1, 1890, and soon after the idea of the elevated sidewalk up Cortlandt Street was taken up by the *Scientific American*, which published some views of the proposed structure, as noted by us on February 15, 1890. Meanwhile the same idea had occurred to a German engineer or architect, H. Rosenbusch, whose pamphlet on the "Future Street of Great Cities" we had occasion to comment upon on the 17th of May last.

Now that the matter has been taken up by the daily press there is reason to hope that before long a popular feeling may be developed in favor of this important movement that will bear fruit in such legislation or other action as may be necessary to put the matter in practical shape.

Fortunately, unlike a subway system or underground road, the elevated sidewalk can be tried on a small scale to begin with, and gradually extended as it may find favor, first, say, from one or more of the North River ferries to Broadway, and then for certain down town streets through other streets, until those three big D's of pedestrianism in lower New York—dirt, delay and danger, shall have forever departed.

THE NEW JERSEY WATER SUPPLY.

THE annual report of the New Jersey State Geologist, C. C. Vermeule, C. E., has an interesting section in regard to the water supply. By this it appears that Jersey City, Newark, Camden, East Orange, Atlantic City, New Brunswick, Perth Amboy, Elizabeth, Burlington, Bordentown, and Mount Holly, ten cities having a population of 465,823, or more than one-third of all in the State, are dissatisfied with their water supply. Of these, cities with an aggregate population of 383,801 have their supply contaminated by other towns, while the supply of towns with a population of 61,694 was naturally poor. The contamination is in the Passaic River on the east and the Delaware on the west. The first-named river, supplying Newark, Jersey City and Bayonne, is contaminated by the sewage of Paterson and Passaic, while the latter, supplying Bordentown, Burlington and Camden, takes the sewage of Trenton. The report says: "It would seem that the Delaware below Trenton, and the Passaic below Paterson, are the natural sewers of their respective districts, and must be abandoned to that use."

Ten towns and villages, with an aggregate population of 30,000, are now constructing or projecting their first water-works. The largest of these is Plainfield, with 8,913 inhabitants, which has for some time been the largest town east of the Mississippi River without a public supply. At least six of the ten new works will get water from wells. Of the 56 water-works in the State which supply towns 43 have streams for their sources and 13 draw from wells. Eight of the latter are large open wells and five driven tube wells.

Classified as to ownership, 38 of the towns are supplied by private corporations and 18 own their systems. Of the latter, 13 were built by the towns, and five by private capital, being afterward bought by the towns. Among the cities not owning their water-works are Paterson, with a population of 63,273; Hoboken, population 37,721, and Elizabeth, population 32,119. Newark, Camden, Trenton, New Brunswick and Burlington bought their works from the companies.

Newark, it should be noted, is already providing for a new supply.

Mr. Vermeule says:

> It would appear to be the time for a more active and direct control of these matters to be assumed by the State. The initiative was taken by the act of 1683, authorizing a commission of State water supply, but this

commission was not continued. The control of the construction of dams, the prevention of unnecessary pollution of streams and guarding of cities against the adoption or use of contaminated sources of supply, would be the proper work of such a commission.

A SAFEGUARD FOR WORKERS IN COMPRESSED AIR.

IT has been found by sad experience that work in compressed air, such as has to be done sometimes in sinking foundations, or in driving subaqueous tunnels, often results in serious injury to health, and sometimes even causes death. The danger does not appear to lie so much in the application of the pressure as in its too rapid removal, especially after being exposed to it for too long a time, and it has been observed that if a workman who has collapsed on coming out of the air-lock, is promptly put back in the chamber, and the pressure then reduced very gradually, he will suffer little, if any, ill effect from what might otherwise prove a serious matter.

Noticing this circumstance, and finding frequent occasion to employ such treatment for the men engaged under his charge on the Hudson River Tunnel, the Resident Engineer in charge of the work, E. W. Moir, determined to make a special arrangement for such cases, as the gradual reduction of the pressure in the air locks often consumed so much time as to interfere with the progress of the work. He has, therefore, designed a separate pressure chamber, in which any man who shows symptoms of suffering from too rapid release of pressure on coming out of the air-lock, can be at once placed, and the pressure relieved as slowly as need be, while, at the same time, opportunity is given for the entrance of a physician, and no interference with the working air-locks is necessary.

The apparatus consists of a cylinder of $\frac{3}{8}$-inch boiler plate some 6 feet in diameter and 16 feet long, lying on its side. The air-tight door opens inward at one end, and in the middle is a partition, with a similar door. Light is given by some bull's eyes in the sides, and the structure is designed and braced for a pressure of 40 pounds per square inch.

The patient is carried in on a stretcher and placed in the inner chamber, the middle door is then closed and the air pressure turned on, which is afterward allowed to slowly escape. Should it be necessary for a physician to enter, the outer chamber will answer as an air-lock for that purpose; or, in case of emergency, it can accommodate another patient on a stretcher.

The chamber is being built by the Cockburn Barrow Company, of Jersey City, and it seems reasonable to expect that it will materially increase the safety and comfort of work in the tunnel.

THE NORFOLK DRY DOCK EXAMINED.

A REPORT that the floor of the new Government Dry Dock, at Norfolk, Va., sank when the cruiser Baltimore was put in it, led the Secretary of the Navy to appoint a special board to examine it, and the report of this board, just submitted, says that "the dock is in good condition, and no remedy is necessary." The receiving ship Franklin, with 4,074 tons displacement, was put in the dock as a test, but the depression noted, of $\frac{1}{8}$ to $\frac{5}{8}$ of on inch, was nearly recovered when the vessel was removed, and is said, by the report, to be no more than is usual from the compression of the timbers. There was no cracking of the cement floor. The board consisted of Captain O. F. Stanton, Constructors W. L. Mintonye and R. W. Steele, and Civil Engineers Thomas C. McCollom and George Mackay.

INLAND NAVIGATION CONGRESS.

THE fourth Inland Navigation Congress will open at Manchester, England, July 28.

The objects of the Congress are: To promote the improvement of inland navigation, and of estuaries; to direct attention to the economical value of navigable waterways; to examine, generally, technical questions relating to the construction and working of canals; to receive the report of the International Statistical Commission, appointed at the last Congress, and to take further steps towards the collection of statistics bearing on inland navigation.

The Congress will include one section devoted to engineering and another given to trading and economy. Invitations to appoint delegates have been sent to the Government of the United States, and to European Governments.

All communications relating to the Congress should be addressed to the Secretary, at Lombard Chambers, 46 Brown Street, Manchester, England.

THE NEW YORK WATER SUPPLY.

THERE is the usual complaint of increasing scarcity of water in New York City, and Public Works Commissioner Gilroy has issued a notice to the people urging economy in its use. He says that already water is being lowered in the reservoirs at the rate of an inch a day, and that this threatens in a little time to seriously increase the deficiency of supply in some localities. At a meeting of the Construction Committee of the Croton Aqueduct Commission, Wednesday, Chief Engineer Fteley said that if work was vigorously prosecuted the Aqueduct could be ready to deliver water by July 15, and action was taken that it is believed will secure that result.

MR. MULLETT'S CLAIM DISALLOWED.

THE Federal Court of Claims has finally dismissed, under the statute of limitations, the claim made by Alfred B. Mullett for compensation as architect of the building now occupied by the State, War and Navy Departments. A press report says that under ordinary circumstances the statute would have begun to run in 1875, when Mr. Mullett retired from service as architect of the Treasury Department, but that it was claimed, that, according to the custom of architects, the amount could not be computed until the work was finshed, and this was not until 1888. The Court, however, decided that the statute must be applied in the usual way, and referred to the Cologne Cathedral and the Washington Monument to illustrate the impracticability of making any different rule. The claim was for about $150,000.

ANNUAL CONVENTION OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS.

THE annual convention of the American Society of Civil Engineers will be held at Cresson, Pa., opening at 10 o'clock, Thursday morning, June 26. There will be one business session, and other sessions for professional discussion. The annual address will be delivered by President Shinn. Members of the Society are specially invited to send to the Secretary papers that they will present to the convention that they may be given places on the programme.

The hotel at Cresson will entertain persons attending the convention for $3 per day. Arrangements have been made with the Trunk Line Association, the Southern Passenger Association and the Central Traffic Association (except in Michigan) for round trip tickets for one and one-third fare, and it is hoped that a similar rate will be given by the New England Passenger Committee and the Western States Passenger Association.

The families of members are invited. A special train will leave New York on the Pennsylvania Railroad at 10 o'clock Wednesday morning, June 25, arriving at Cresson in the afternoon. This train will be run as a second section of the Chicago limited. The cost of accommodations on this train will be about the same as on ordinary Pullman cars. Other special accommodations will be arranged for if it appears that any are needed. Further information may be had by addressing the Secretary, John Bogart, 127 East Twenty-third Street, New York City.

NOTES.

THE Suez Canal traffic for the last quarter of 1889, as reported by S. G. Broodlunt, American Consular Agent, included 776 vessels of 1,447,815 total tons burden. Eleven vessels of 24,392 total tons were American.

THE Baltimore *Sun* publishes a report to the effect that an association of French capitalists have got control of the stock of the Maryland and Delaware Ship Canal Company, and will immediately construct the work. The route selected is up the Sassafras River from Chesapeake Bay, and across the peninsula to Blackbird Creek and the Delaware River. It is said that there are but 7½ miles of solid cut on the line, and that the whole distance to be covered, including the dredging of marshes, is but 14½ miles.

NEW ORLEANS is to have public baths, with accommodations for men and for women and children in separate buildings arranged on either side of the Sanitary Association's flushing pump, which raises water from the river for flushing gutters.

A NEWSPAPER correspondent reports that not less than $1,000,000 has been spent in rebuilding Johnstown, Pa., which was swept away a year ago, and that real estate sells higher than before the flood.

THE arrival of 5,000 tons of steel rails from Pittsburg, Pa., at Piedras Negras, Mexico, is reported by Consul Fechet of that place. These are the first American rails sent to Mexico, and it is said that they can now be furnished cheaper than European rails.

THE first fellowship in architecture of Columbia College has been awarded to Arthur A. Stoughton, of New York City. It amounts to $1,300, and the money is to be spent in travel and study abroad. R. M. Hunt, C. F. McKim, T. Hastings and A. Rotch were the Awarding Committee.

OBITUARY.

FRANCIS C. LOWTHORP, M. Am. Soc. C. E., died at Trenton, N. J., June 1, at the age of 81 years. He invented a railroad turntable and designed many railroad bridges, among which was the pivot drawbridge over Newark Bay, built by the Central Railroad of New Jersey.

WILLIAM L. CRITTENDEN, C. E., in charge of the Third Division of the Government Survey in the upper Green River Country, Wyoming, was killed by Indians, June 1, with E. W. Timburlake, George Woods, and Henry Overmeyer, chainmen. Jesse Lee, Assistant Engineer, was badly wounded and left for dead, but survived. A party of Indians visited the camp, drank all their own whiskey and then demanded more from the engineers, and finally made a sudden attack upon the five whites, and killed four of them on the spot. Mr. Crittenden was about 45 years of age.

PERSONAL.

SAMUEL N. DAUGHERTY has been re-elected City Engineer of Xenia, O.

ARTHUR G. ERDMANN, architect, recently of Cincinnati, has opened an office in the Newsalt Block, corner of Fourth and Jefferson Streets, Dayton, O.

BRIGHAM & SPOFFORD, architects of the Massachusetts State House extension, have moved from Milk Street to 22 Beacon Street, Boston, Mass.

E. S. DAVIS, C. E., for the last eight years in the United States Surveyor-General's office at Denver, Col., has resigned, and accepted a position with the sewerage department of Boston, Mass.

J. C. RAWN, has been appointed manager of the Roanoke Gas and Water Company, of Roanoke, Va. He will continue to discharge the duties of Engineer-in-Charge of the Clench Valley Extension of the N. & W. R. R., which he has held for the past three years, with headquarters at Roanoke.

COMING MEETINGS.

THE ninth annual meeting of the New England Water-Works Association will be held at Portland, Me., June 11, 12 and 13.

THE annual convention of the American Society of Civil Engineers will open at Cresson, Pa., at 10 o'clock Thursday morning, June 26.

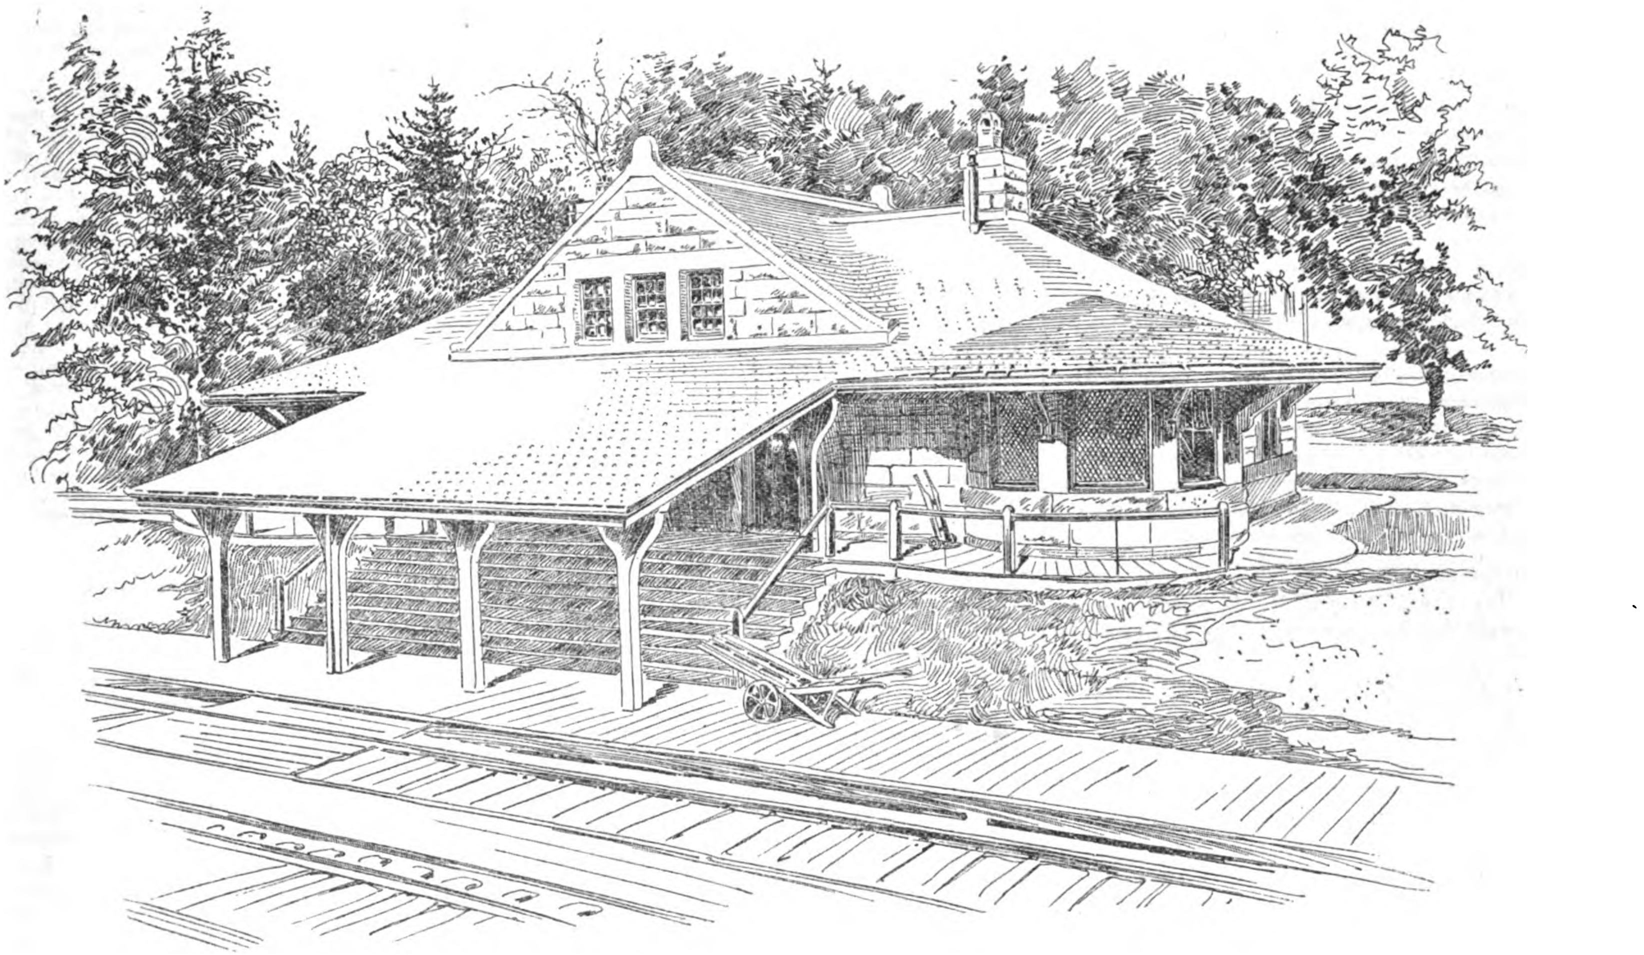
ENGINEERING SOCIETIES.

THE ENGINEERS' CLUB OF ST. LOUIS held a meeting May 21, with Professor Nipher in the chair, W. H. Bryan, secretary, and 19 members and 3 visitors present.

The paper of the evening, by George A. Brown, entitled "The Function of the Government in a Plan for General Irrigation," was read by Professor Johnson. It discussed at some length the necessity of providing some more complete and systematic method of dealing with the problem of the artificial distribution of water for irrigation, this problem being one of great importance, especially in the Western States and Territories. The Government is now asked to determine the amount of water available for the purpose and to provide laws regarding its distribution and apportionment. The author thought that the Government should give a title to certain water privileges, the same as it gives to land. The author was connected for a short time last season with the irrigation survey work done by the Government in Western Nevada, under the direction of Maj. J. W. Powell.

In the discussion, Professor Nipher said that experiments extending over a long period of years had demonstrated that the apparent increase in rain-fall in forests was due to the fact that the rain caught in the gauges was not affected by wind currents. Improved forms of rain gauges had shown that there was no actual difference between the amount of rain falling in forests and in open places.



RAILROAD STATION AT WELLESLEY HILLS, MASS.—H. H. RICHARDSON, ARCHITECT, BOSTON, MASS.

Mr. Robert Moore stated that such investigations as he had been able to make had satisfied him that the popular opinion that forests increased the amount of rain-fall was a fallacy, and he was glad to see the matter set at rest authoritatively. Messrs. Johnson, Blaisdell and Curtis also took part in the discussion.

THE AMERICAN SOCIETY OF CIVIL ENGINEERS held a regular meeting June 4, with President W. P. Shinn in the chair.

The death at Trenton, N. J., of Francis C. Lowthorp, a pioneer iron bridge builder, was announced, and followed by some biographical remarks.

Some informal notes of a visit to the line of the Panama Canal, from the journal of a Civil Engineer, by J. Foster Crowell were read, and the progress of arrangements for the Cresson convention was announced. Visits are proposed to the Jeanette Glass Works, to Johnstown, and to Altoona and other points of local interest, and the indications promise a full attendance.

Adjournment was followed by the usual collation.

The following candidates were declared elected :

As Members.—Rawlinson Tennant Bayliss, Resident Director and Manager Montana Company (Ltd) of London, operating the Drum Lummon (Gold) Mine at Marysville, Montana, in charge of the Company's business including construction of mills and machinery for the mining and reduction of 90,000 tons of ore per annum. Marysville, Mont.; Harry Winter Edwards, engaged on construction of new flour dock and warehouses with title of Division Engineer, West Superior, Wis ; John Edwin Greiner, Assistant Engineer, office of Engineer of Bridges B. & O. R. R., Baltimore, Md.; Carl Robert Grimm, engaged with New Jersey Steel and Iron Company; John Baillie Henderson, Government Hydraulic Engineer in charge of Water Supply Department, Brisbane, Queensland, Australia; Karl Emil Hilgard, Principal Assistant Engineer in charge Design and Superintendence of Construction Fourth Street Extension Chesapeake and Ohio Railroad, Cincinnati, O.; Gilbert Hodges, engaged in general engineering, Boston, Mass.: Charles Comstock Hopkins, Engineer of Sewers for Gloversville, N. Y.; Rice Creek Reservoir and Extension; Gloversville Water-Works, and Addison, N. Y., Water-Works; Andrew Langstaff Johnston, Chief Engineer Southside Land and Improvement Company of Virginia; and Richmond and Southside Electric Railway and Consolidated lines; Engineer Manchester Sewerage Company, Richmond, Va.; Claude William Kinder, Engineer-in-Chief to China Railway Company, Tientsin, North China; William McKelvy Marple, Assistant Engineer on construction of dams and reservoirs for same company, Scranton, Pa.; Charles Eyra Marvin, Time Roadmaster Main Stem Central Railroad of Georgia in charge Road Department, Bridges, Buildings and Water Supply, Macon, Ga.; Mitsugu Sengoku, now Engineer to the State Railway, Tokio, Japan; Reuben Shirreffs, Second Assistant Engineer East Jersey Water Company, Paterson, N. J.; Charles Wallace Walton, Superintendent and Engineer in charge construction and operation mills and log tramways for Anchor Manufacturing Company, Detroit, Mich.; Ethelbert George Woodford, State Mining Engineer, Department of Mines, to the Transvaal Republic, Pretoria, Transvaal.

As Juniors.—Wainwright Parish, Resident Engineer in charge construction Keeseville, Ausable Chasm and Champlain Railroad, and Assistant Engineer D. & H. C. Co., Albany, N. Y.; George Ernest Roehm, Bridge Inspector of Michigan Central Railroad, Detroit, Mich.; William Lee Sisson, Assistant Engineer to Engineer Maintenance of Way B. & O. R. R., Baltimore, Md.; Charles Horton Smith, Assistant Engineer New York, Ontario and Western Railway, Middletown, N. Y.

THE ENGINEERS' CLUB OF KANSAS CITY held a meeting May 12 with F. E. Sickels in the chair, K. Allen, Secretary, and 11 members present.

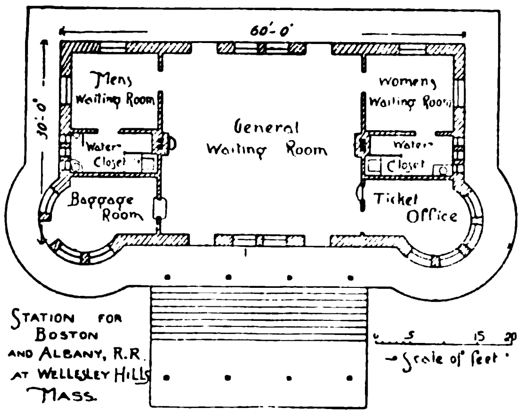
A. J. Mason read, for the Committee on Affiliation of Engineering Societies, abstracts from a communication from Prof. J. B. Johnson, of St. Louis, proposing a federation of the leading engineering societies. Mr. Mason also presented a brief verbal report for the Committee on Affiliation adverse to a connection of the local societies with the American Society. The report was accepted and the committee requested to continue.

Mr. Allen thought the field of work of the local societies was quite distinct from that of the American Society, and that joint publications would be unnecessarily expensive and cumbersome for many members.

Messrs. Filley and Stone were opposed to the proposed "Federation" having a local habitation, while Messrs. Sickles and Mason held the opposite view, and thought that by selecting the city of Washington especial advantages would be attained without incurring hostility.

A. Clifford Thomson was declared elected a member.

The secretary read for the author, Robert M. Sheridan, a paper on "The Evolution of the Elevator."



Beginning with the year 1855 the paper traced the growth of the elevator engine from the oscillating cylinder reversing engines (which marked the first step in the development of this branch of engineering) to the perfected steam worm-geared passenger elevator engine in use at the present time. A summary of the various steps embracing the charges in engines of this class was presented. The vertical cylinder hydraulic machine was described and compared with the perfected horizontal cylinder elevator and its improvements. The workings and advantages of the lever operating device in its connection with the auxiliary valve with the independent automatic stop valve were explained. A description of the principle of the centrifugal governnor attached to the car as a safety device was given, accompanied by a general statement concerning the present requisities for elevator service, covering the point of absolute regulation at the highest speeds by the use of the improvements mentioned. The travel of the tower elevator in the Chicago Auditorium building, passing through a distance of 220 feet at a speed of about seven miles per hour, or 600 feet per minute, was cited as a case in point covering the various demands upon elevator service at the present time. The future of the work, judging by the past, includes the elevator's evolution along the lines now set, keeping pace with the demand for buildings that tower nearer the sky year by year.

The Western Society of Engineers held a meeting at Chicago, May 7, with President L. E. Cooley in the chair, John W. Weston Secretary, and about 75 members and visitors present. Dwight H. Perkins, George F. Wightman, Edward W. Dewey, John M. Ewen, Ralph M. Shankland, Walker Miller, Frank G. Ewald and Charles Hansel were elected members.

A communication from the American Society of Civil Engineers in regard to relations between the associations, which had been delayed, was received, and Messrs. Williams, Herr, Chanute, Nagle and Morison were appointed a committee to respond in regard to the matter, but it was understood that they would not commit the society.

"The Railway Problem of Chicago," the subject assigned for discussion at the meeting, was brought up, and majority and minority reports from the committee appointed to consider the matter were read. Ossian Guthrie presented a paper bearing on the subject under discussion, which was largely a history of the growth of Chicago.

C. J. Rooney presented some figures in regard to viaduct and bridge work done in the city, and A. F. Robinson read a paper on 4-track viaducts, giving estimates of cost for steel with brick piers, and for structures wholly of brick. There was discussion of the subject by Messrs. Morgan, Morison, Wallace, Nourse, Northway, President Cooley, Fish, Herr and MacDonald.

The Engineers' Club of Philadelphia, held a meeting May 17, with President H. W. Spangler in the chair, Howard Murphy, Secretary, and 35 members and two visitors present.

Prof. J. W. Redway read a paper on the "Physical Geography of the Mississippi River."

The Secretary presented, for George W. Creighton, a paper on "Rail Joints."

A TOWER PROJECTED IN CHICAGO.

A tower of iron and steel, 1,500 feet high, has been designed by Charles Kinkle and G. R. Pohl, architects, of Washington, D. C., to be erected in connection with the World's Fair at Chicago, and the *Tribune* of that city reports that a number of capitalists in New York, Washington and Chicago are behind the enterprise and will erect the structure without asking aid of the Fair managers or anybody else. The only name given is that of M. B. Bailey, a contractor and builder, who is one of the incorporators. The tower, according to the report, is to be erected within a mile of the commercial center of the city, regardless of the location of the Fair, be permanent, and cost over $2,000,000. The base will be 480 feet in diameter, with a "skeleton of steel-framed lattice work on 16 hyperbolic curved legs"; and there are plans for a hall with a capacity to seat 30,000 people and a hotel with 4,000 rooms in the structure, space for the public library, rooms for the Grand Army, public institutions, etc. There are to be eight elevators for the first 100 feet, four to 200 feet, four to 400 feet, and two to the top. The floors will be 33 feet apart.

The Suez Canal traffic for the last quarter of 1889, as reported by S. G. Broadbent, American Consular Agent, included 776 vessels of 1,447,815 total tons burden. Eleven vessels of 24,392 total tons were American. The profits of the Canal for 1889 are reported to have been 37,212,925 francs. The average time of passing through the canal has been diminished four hours.

DESIRABLE EFFICIENCY OF HYDRANTS IN CONNECTION WITH WATER-WORKS.*

The suppression of fire is the most important factor we have to contend with. Convince the citizens of any city or town that they have a good fire protection, and the water-works become popular. The mains should be of a sufficient dimension to supply with ease the hydrants placed thereon, and they should never be less than 6-inch inlets. Many cities and towns make a great mistake in trying to reduce the cost of the works by using small mains and small hydrants. I can recall to mind instances where 10, 15, and even 20 hydrants are placed on a 6-inch main with no reinforcement, and the citizens expect that all of them could be used if wanted. It is a well known fact that four good fire streams is all that can be expected from that class of mains. I am reminded of an instance, related by a friend, where two competing fire companies were trying to put out a fire in a house, and each one was using two hydrants situated on a 6-inch main, with no effect on the fire, and as neither would give up to the other, the house was burned. If both companies had shut one hydrant each they would have been effective, and the house would have been saved. Another mistake that is made is locating hydrants too far apart, where you have mains of sufficient magnitude to supply. Hydrants are cheaper than hose, and will last longer with less care; besides you get better results with short lines of hose. The friction in the hose overcomes the pressure, and the effectiveness is lost to a large extent. The relative cost with the life of the hydrant in comparison with the life of the hose, is largely in favor of the closeness of hydrants. But they say the hydrants cost money; admit it does, what is the cost in comparison to its worth when you want it, and the location of one hydrant might save a hundred-thousand-dollar conflagration, or even more. Ask your chiefs of the fire department if they think you have too many hydrants where the pipes are of the capacity equal to the demand, and they will tell you no! But where they are not, the Fire Department is often censured for that which they are not to blame for, and in most of the cases the cause is traced to small mains and hydrants. The hydrant is looked upon by some as a useless thing because it is not used, or, in other words, because we do not have fires. We have on our works hundreds of hydrants that have never been opened for fire purposes in the past ten years, and yet I would not know where to discard one; in fact we do not wish to use them only when we have a fire, and then they are wanted more than their value. We never want a fire; it is like the insurance on our houses; we pay, but do not want them to burn. I remember a few years ago some of our citizens said we did not use them, and therefore ought not to pay for them. About that time we had a large lumber yard on fire, and it was a very dry time, and the wind was blowing in a direction which carried the sparks over the business part of the city. At one time we had the roofs of 60 buildings on fire. The hydrants were brought into service, playing 52 fire streams in that location, and in connection with the sill-cocks, which nearly every house has for garden hose, a conflagration was prevented which was liable to have cost a million of dollars. These same people said after that there were no useless hydrants in the city. All hydrants should be easy of access, and to have them so I believe the post hydrant is the most effective. I also believe the independent gate on each outlet for the hose is of more value than the extra cost of the same, and the day is not far distant when they will be more universally used. To illustrate: Take a fire just started, with two or four streams playing, and one line of hose bursts, you have to shut off the other streams to replace the hose. During the delay the fire may get such headway as to cause great damage, but in the use of the independent gate the other streams play right along. The first minute on a fire is worth hours at some other stage of the conflagration. Firemen have chucks which are screwed on to the hydrant or hose, but they are unwieldy in comparison with the gate. I know from experience that where you have a heavy pressure you can regulate it with the gate very easily. Superintendents of works should always look well, in making extensions of mains, to the efficiency of the hydrant. Another important factor is fast coming into use—the automatic sprinkers, used only in case of fire. They do their work before the hydrant is called for, and in case they fail by some unforeseen circumstance, they should be governed by gates so that when their efficiency is gone they can be easily shut off in the street. We have in our city miles of automatic sprinkler pipe, and fires occur daily that are never reported. Hydrants never should be used only for fire purposes, in cases of necessity. Some cities allow them to be used for sprinkling carts or watering down the streets, and other purposes, by inexperienced men. Then the firemen find them out of order, and the Superintendent has to stand the blame, as no one knows who did it. They should be inspected as often as twice a year and properly oiled, but never inspected in extremely cold weather, as by the introduction of water they are liable to stick with frost. Of course, there are certain kinds of flush hydrants that have to be looked after in extreme cold weather more frequently. With an experience of ten years with from 400 to 800 hydrants, we have never had but little trouble with frost. Ours are post hydrants with rubber disks, and shut against the pressure, and I have never had to remove one as yet. After having built your works it is well to know what you can do if called upon in extreme cases. I had faith to believe we could play 70 fire streams at once and maintain 80 pounds pressure while playing, and I so stated at the last convention at Louisville. On September 19, 1889, our Chief Engineer, Mr. John Brierly, was invited to play 70 one-inch fire streams through 50 feet of hose at once. This was successfully accomplished, holding a maximum pressure of 80 pounds during the time the test was made. The test was made on the 20 and 24-inch force main, 3½ miles long, leading from the pumps through the center of the city to the storage reservoir on the heights, at an elevation of 301 feet above tide-water, the engines with a capacity of 12,000,000 gallons all being running; 4,040 feet of this main was used, and the streams were taken from nine 6-wayed and eight 2-wayed hydrants. Four Edson recording gauges were placed on the line located so as to give the best results of the loss of pressure, and one before each pump. The cards show with what nicety and precision they exemplify and verify the pressure. By the use of these gauges we were enabled to verify facts which we should have been unable to do without them. The pressure at the No. 1 engine, which was the nearest to the draught of water, was reduced 24 pounds; at the No. 2, 10 pounds, and at the No. 3, 10 pounds. We were delivering during the trial 15,500 gallons per minute. The capacity of the pumps was 12,000,000 gallons per day, and the draught on the reservoir was 10,000,000 gallons per day, including the supply of the city at the same time, making a consumption of 22,000,000 gallons per day. I am satisfied that by distributing the hydrants over a larger territory we would be able to play 100 fire streams and maintain the same pressure. I contend that originators of water-works should always bear in mind that the efficiency of the hydrants is of the most importance, and should always be looked after with the greatest care. Superintendents having charge of works in making extensions should always try to connect all dead ends, so as to reinforce the supply to the hydrants, and make them more efficient as their works increase in magnitude.

Chief Scannell, of the San Francisco Fire Department, with the aid of his most powerful engine, recently gave the Grand Jury and the Mayor and Supervisors of that city an ocular demonstration of the crying need for proper protection against fire of additional fire hydrants. Of course these gentlemen knew perfectly well that in many parts of the city the distance between the hydrants was from 1,500 to 2,000 feet, but it is probable that they never before realized so thoroughly how great was the loss in power of a stream caused by the friction in the long line of hose thus made necessary. It is safe to say that they were somewhat surprised when, after seeing water thrown 206 feet through 100 feet of hose, the pressure at the nozzle standing at 90 pounds; 900 feet more of hose were coupled on and the enfeebled stream fell to the ground just 54 feet from the nozzle, where the pressure mark was but six pounds.

ANNUAL REPORTS.

The water-works report of Toledo, O., for 1889, H. C. Cotter Superintendent, shows that there were 39,016 feet of 4 to 12 inch mains laid during the year, making 367,791 feet in all; 29 hydrants set, making 464 in all; 448 services were added, making 3,384 in all, and 43 meters added, making 377 in use. There were 1,906,484,100 gallons of water pumped an average height of 167 feet, at a cost of $11,474, including $4,000 for fuel; in this case "fuel gas." The total amount charged to current expense account was $28,915, but $7,000 of this was for repairs to pumps, which the report says should be distributed over other years. There was $42,138 charged to construction account.

The report is accompanied by a letter to the water-works trustees, signed by George W. Davis, trustee from 1883 to 1889, and J. D. Cook, Chief Engineer and Superintendent of the works from 1873 to 1879. This communication refers to the history of the works and to a detailed recommendation for purifying the water by settling reservoirs in the report for 1885. The letter also urges that the increasing difference between high and low water in the Maumee River is making new pumping machinery necessary, and gives some figures showing the relative financial aspect of the proposed improvements. It is said that, as nearly as can be ascertained, the cost of water-works in all cities in the United States and Canada having 70,000 or more population averages $27.50 per capita, and the net earnings $1.42 per capita, while in Toledo, with the cost of the improvements added, the works would represent but $14.58 per capita of population, and the net earnings for 1889 were but $0.46.

How much importance is attached by the Germans to good connection by means of waterways, and easy navigation thereon, is evident, says the London *Builder*, if one bears in mind that, besides the long list of smaller works which outsiders scarcely hear of, a Danube-Oder Canal is being planned; that the Rhine is not only to be connected with the river Maas and the Dortmund-Ems Canal, but also with the Elbe, which latter is to have a new connection with the Trave; and that complicated schemes are being prepared in reference to the deepening of the Rhine and Elbe, so as to make them navigable for ships of greater tonnage.

NEW OFFICES OF ADLER & SULLIVAN, ARCHITECTS, CHICAGO.

In connection with the articles on "The Organization of An Architect's Office," published in The Engineering and Building Record recently, the accompanying illustrations of the new offices of Messrs. Adler & Sullivan, of Chicago, will prove interesting.

The offices are in the tower of the Auditorium Building, of which these gentlemen were the architects, occupying the sixteenth and seventeenth stories, 206 feet above the sidewalk level. The plans show very clearly the general arrangement adopted and require no explanation.

PROPOSED WATER-WORKS AND SEWERAGE SYSTEM FOR BARRIE.

The town of Barrie, Ont., situated at the head of Kempenfeldt Bay, an arm of Lake Simcoe, has begun to feel the need of a water supply and a sewerage system and Willis Chipman, civil and sanitary engineer, of Toronto, Ont., has been requested to recommend plans for the same.

In determining the amount of water required he assumes that 250,000 gallons a day will be sufficient for the present domestic uses of the estimated population of 6,000 people, and doubles it to provide for future increase. For fire purposes he estimates that 700 gallons a minute should be allowed so as to supply at least three fire streams 1⅛ inches in diameter and 100 feet high, or at the rate of 1,008,000 gallons per day, making a total of 1,040 gallons a minute, or 1,500,000 gallons a day.

As to source of supply, after comparing the water from the bay and from various springs and creeks, he recommends the use of artesian, or more properly, driven wells, located near the bay about 50 feet apart and 4 inches in diameter, a pit to be excavated about each well to the level of the water in the bay. Water is found about 100 feet below this level and rises about 20 feet above it. The wells are to be connected by a suction main to the pumping station. Some 20 of such wells have been sunk in the town for various purposes with very satisfactory results, yielding through a 2 or 3-inch tube a flow of 20 to 30 gallons per minute of good water at a height of about 15 feet above the bay.

For pumping machinery a duplicate set of compound duplex engines is recommended with a capacity to easily deliver 1,040 gallons per minute against a head of 150 feet for domestic service, or 150 pounds for fire service. A stand-pipe on high ground, 25 feet in diameter and 50 feet high, is also advised.

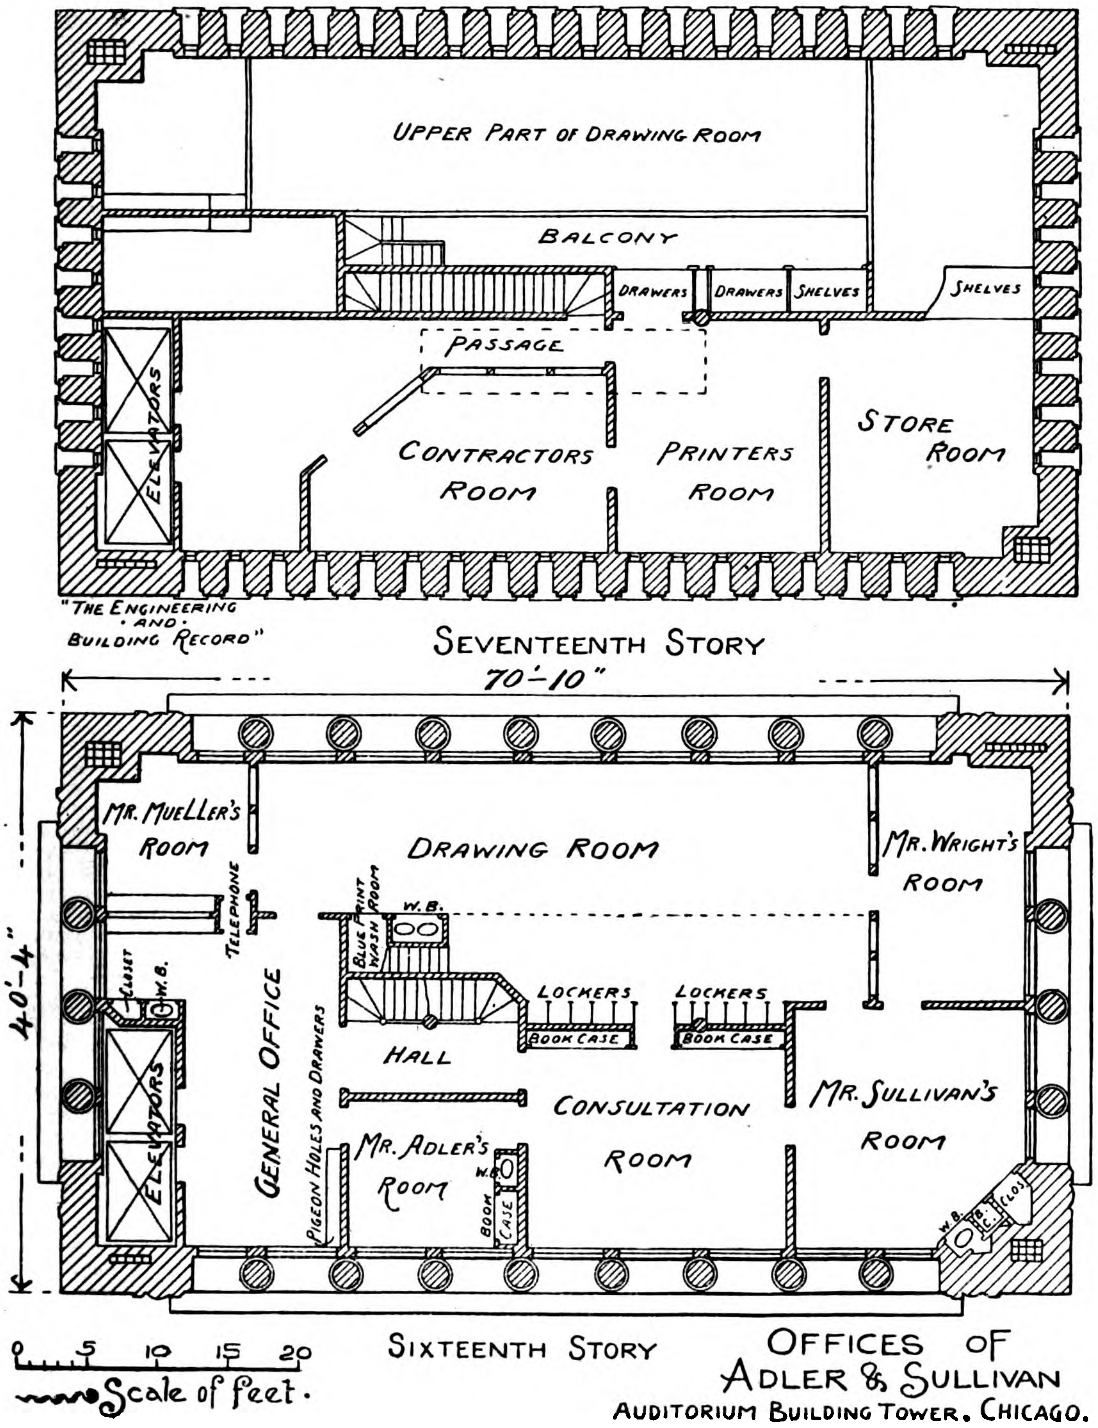
The estimated expense is as follows: Pump house, site, chimney and coal shed, $5,000; Pumping machinery, boilers, etc., $8,000; 27,000 feet of 10 to 4-inch distribution mains with 50 hydrants and necessary valves, $30,000; stand-pipe, $7,000; engineering and other expenses, $3,000; eight wells with connecting pipes, valves, valve chambers, etc., $4,000; total, $57,000. The annual running expenses for the first few years are estimated at $3,000, and the receipts are expected to equal that amount at the end of four years.

Mr. Chipman concludes his report by a strong argument in favor of municipal rather than private ownership and control of the water supply, and gives a tabular synopsis of statistics of water-works in Ontario bearing on the question.

For the sewerage the adoption of the modified separate system is recommended, the smallest size of sewer to be 8 inches; automatic flush tanks to be constructed at the heads of all sewers; sub-soil and cellar water to be removed by agricultural drain tiles laid alongside of and in the same trenches with the sewers; roof water to be admitted to the sewers only when necessary and when connections are properly trapped and storm water to be excluded.

For the larger part of the town a single cast-iron outlet extending some 300 feet into the bay is expected to suffice. For the rest of the town several separate outlets may be required.

The use of salt glazed pipes is advised, with manholes at all junctions and street intersections and changes of line and grade. The soil is sandy, and it is expected that the sewers can be laid at an average depth of 8 feet and at an average cost of $1.50 per lineal foot. No estimates of total length or cost are given.



OFFICES OF ADLER & SULLIVAN
AUDITORIUM BUILDING TOWER, CHICAGO.

THE DAVENPORT, IOWA, WATER-WORKS.

According to particulars bearing on the Davenport, Iowa, Water-Works, given by James P. Donahue, Secretary of the Davenport Water Company, the water-works system of that town represents an investment of nearly $1,000,000.

The Davenport Water Company is a private corporation, which was organized through the efforts of the late ex-Mayor Michael Donahue and his brother, the late Col. Peter Donahue, of San Francisco. The work comprises two pumping stations and a reservoir, and about 34 miles of water mains, from 4 to 16 inches in diameter. There are 308 public and 9 private fire hydrants, and about 1,800 water consumers.

The pumping capacity of Station No. 1 is 11,000,000 gallons in 24 hours. This station comprises the original works, and is situated on the Mississippi River. The pump-house is a large two-story building, 68 by 93 feet, including the boiler room. There are two sets of pumping engines in this station. Pumping Engine No. 1 is a condensing set of duplex engines of 5,000,000 gallons capacity per 24 hours, built by the Clapp & Jones Manufacturing Company. Pumping Engine No. 2, which has been more recently completed, is a high-duty Worthington compound condensing duplex engine of the latest design, and capable of delivering 6,000,000 gallons of water in 24 hours against a head of 345 feet. There has also been placed in this station within the last year a new triple set of steel boilers. At this station the smoke stack is 133 feet high, and one of the largest in the West. There is also one of the largest steam gongs ever built.

The pumping capacity of Station No. 2 is 5,000,000 gallons in 24 hours. The bluff or high service is supplied by reservoir water delivered by the pumps at this station, which are located at the reservoir. These engines are vertical—of the duplex compound condensing type. In 30 seconds the pumps of Station No. 2, which are continually running for the high service, can be changed so as to pump into the gravity service, and pump down hill in case the reservoir pressure is not sufficient for fire purposes. Then, too, there is another resource in case of fire, and that is Pumping Station No. 1, which can be set in motion and give all the additional pressure necessary. This means that the piping system is so designed that the pumps at Station No. 1 and Station No. 2 can pump at the same time, at their respective ends of the distribution mains, thereby insuring increased pressure—an almost unlimited supply of water and pressure in time of fire.

The reservoir has a capacity of 5,000 000 gallons. It was built in 1883, at a cost of about $100,000. It has an elevation of 115 feet. The purity of the water is assured, not only from the fact that no town of any size is drained within 40 miles, but also from the manner in which the water is taken from the river. The company tunneled under the bed of the river until the channel was reached, where the water runs over solid rock for several miles, with a current never less than six miles an hour. The water is delivered through this long tunnel into a large well 15 feet in diameter and 30 feet deep, and the water is, to a certain extent, filtered in this well before it supplies Pumping Station No. 1.

The water-works are managed by the following officers: Nicholas Kuhnen, President; James P. Donahue, Vice-President and Secretary; Thomas N. Hooper, Chief Engineer and Inspector. These officers, with Col. James M. Donahue, of San Francisco; Hon. J. H. Murphy and F. H. Griggs, of Davenport, constitute the Board of Directors.

SELBY AVENUE BRIDGE FLOOR.

The recent extension of a street cable railroad in St. Paul, Minn., made it necessary to build an iron highway and street car bridge on Selby Avenue, over the tracks of the Chicago, Milwaukee and St. Paul Railroad. This bridge consists of three thorough truss spans level and plate girder approach viaducts, on 6 per cent. grade. The total length of the structure is about 720 feet, with a width between railways of 41 feet 9 inches.

Figure 1 is a half cross section through a plate girder span, the part above V V being essentially the same as a cross section through a truss span. The bridge is symmetrical about the center line C C. The outer part, A B, of the roadway has a plank floor, on which a wooden block pavement, like that on the adjacent street, is laid. The remainder of the roadway has a buckle plate floor, B B B, with concrete ballast, on which similar paving blocks are set. I I are the track rails, and H H are the cable conduit rails. Access to the cable is had at every second panel through manholes, D D, located at each cable-bearing pulley. P is a sheet-iron trough shielding the cable.

Figure 2 is a plan of some of the center part of the roadway, with the concrete and paving blocks removed.

Figure 3 is a section and elevation at Z Z, Fig. 2; Fig. 4 is a section at Y Y; Fig. 5 is a section at X X; Fig. 6 is a plan of buckle-plates at the abutment masonry; Fig. 8 is a section at W W; Fig. 7 is a longitudinal section parallel to W W, through the outer part of the roadway, and Fig. 9 is a plan of the manhole frame and cast-iron cover (D, Fig. 1), with sections at U U and V V.

The buckle plates B B, etc., are riveted on their transverse edges to the floor joist C C, etc., and their longitudinal edges are riveted to the T bar splices D D, etc. The track rails I I and the conduit rails H H are supported by the cross-web plates F F, etc., to which they are connected by angle clips G G, etc. The edges of these plates are planed at A A for accurate bearing with the bottoms of the rails.

The double joist C' C' are for an expansion joint, and the opening between them is covered by an iron plate with beveled edges that extends across the full width of the roadway. The longitudinal angles M M, etc., and the rails, with the transverse vertical plates E E, etc., and part of the plates F F, etc., form side barriers to keep the concrete in place before it sets.

The iron work of this bridge will cost about $70,000, and is being built by the Edgemoor Bridge Co., of Wilmington, Del., in accordance with the plans and specifications of L. W. Rundlett, City Engineer of St. Paul, who furnished the data from which the above illustrations have been prepared.

In a paper on "Asphalt in Building Construction," recently read before the Architectural Students' League of Brooklyn, T. H. Boorman stated that Theophilus P. Chandler, Jr., architect, of Philadelphia, is using rock asphalt on every floor of a large apartment house; the carpets will lay on the asphalt, being fastened down to narrow strips of wood set against the partitions when the asphalt is laid.

EXPERIENCE WITH ARTESIAN WELLS AT ROCKFORD, ILL,*

About 90 miles northwest of Chicago, with an elevation above Lake Michigan of 128 feet, and above sea level of 708 feet, on the banks of Rock River, running almost through its center, is situated the city of Rockford, a place of about 25,000 inhabitants, with a direct pressure system of water-works and 42 miles of mains.

The southern boundary of the collecting area, from which our wells draw their supply, is about 65 miles northwest of Rockford, and its extent, roundly estimated, is about 4,000 square miles; it has an effective elevation of 270 feet above Lake Michigan (although parts of it rise as high as 400 feet), and 850 feet above sea level.

In this area the Potsdam sandstone crops out at the surface. The difference in elevation between the two points is 142 feet, and the Potsdam sandstone being entered by the drill about 500 feet below the surface at Rockford, shows that water-bearing rock to have a dip of about 650 feet. Over this rock is a layer of magnesian limestone 100 feet thick, which, being impervious, confines the water to the lower rock.

Our first well was drilled 1,530 feet deep, with an 8-inch bore, and flowed at the surface about 1,000,000 gallons in 24 hours, the water rising by test 28 feet above the ground. This showed a friction loss of 114 feet between the basin and the well, or about 1.75 feet per mile.

We continued the work of sinking wells, and soon had four connected with the pumps, whose combined flow was about 3,000,000 gallons per 24 hours, but this flow was not permanent, and soon began to decrease, so that about 2,500,000 gallons per 24 hours was the limit. At this time a paper mill, situated one mile south of us on ground 17 feet lower, drilled a well which affected ours still more, and we drilled one more, but our own supply did not improve to the extent we desired or expected, and an investigation showed that the No. 1 well was flowing at the surface only 70,000 gallons, and at point of connection 210,000 gallons in 24 hours, and we decided to repipe and repack this well down through the upper stratas in the magnesian and note results. When finished, the result was a flow of 177,000 gallons of surface, and about 400,000 gallons at point of connection.

The same work on No. 4, resulted in an increase from 142,000 to 254,000 gallons at surface with a delivery at point of connection of about 700,000 gallons in 24 hours.

We are now at work on the other wells, and the total benefit cannot be determined until all wells are repiped.

We note that our wells were faulty in construction. The repiping shows conclusively that the wells were leaking badly in the upper stratas.

One well will under certain conditions affect another, the conditions in our case being a fine water-bearing sandstone, causing too much friction, and elevation.

A multiplicity of wells of small diameter, close enough together to make the conduit or suction of any value at point of delivery to pumps, will interfere with each other to such an extent as to limit the supply, and if to overcome this interference the distance one from another is increased, the friction in conduit is so great as to overcome any gain on account of non-interference. This we demonstrate in our No. 5, which is 700 feet distant from the nearest one of the other four.

The flow of our wells is not uniform. Extremely dry weather for any length of time at the basin affects the flow, decreasing it gradually, and it is months, frequently, before we notice a return to normal conditions. These wells, being all connected to one conduit and through the suction into the pit, are so arranged that any one of them can be piped out above ground and shut off from the main pipe, and by so piping either one of the five, and continuing pumping from the other four we find that the highest the water will raise above ground is eight feet, and this head will gradually lower as we increase the pumpage and lower the water in the pit, showing conclusively that we have more discharging capacity in the five holes than the porosity of the sand rock will supply in the area in which they are drilled.

Artesian wells at Galena, Ills.; Dubuque, Iowa, and Prairie DuChein, Wis., all supplied from the same basin, have a much stronger flow than ours, and investigation shows that at those places the Potsdam is much more porous, and in some instances delivers to the 8-inch hole more water than that hole can deliver at the surface. We also find that while the area of the collecting basin is about 4,000 square miles, only a small portion contributes toward our supply, owing to the dip of the rock preponderating toward the west and southwest.

SOME OBSERVATIONS AND SUGGESTIONS CONCERNING WATER-WORKS CONSTRUCTION.†

The Water Supply.—The first requisite of any system is, of course, an abundant supply of the best water. For supplies for small towns in the East ground water from collecting or driven wells is being largely used. Stored in covered reservoirs or tanks it gives almost universal satisfaction.

The Pipe System.—The pipes forming the distribution system should be of sufficient size to furnish good fire streams. With this in view, 6-inch pipe is small enough, except for short cross streets, where there are no hydrants, or to connect what might otherwise be dead-ends. If a pipe is a dead-end and has no hydrant upon it, or has one only to be used as a blow-off, there is this advantage in having it small, that less water is wasted in blowing it off, and the consumers get fresher water than from a large pipe.

If possible, there should be none of these pipes with plugged ends, but every pipe should be part of a circuit.

The size of pipes could be much reduced if only domestic service were to be provided for. A fire of any size requires immense quantities of water to extinguish it, and this must be applied quickly in large volumes. This requires large pipes.

Hose and Hydrants.—The recommendation of J. R. Freeman, in his valuable paper read before the American Society of Civil Engineers, of New York, and later, in a modified form, before the New England Water-Works Association, at Boston, that the size of fire hose be increased from 2½ to 3 inches in diameter, is worthy of the most serious consideration. It seems perfectly feasible that all, except the few lengths nearest the nozzle, which may have to be used from a ladder, should be of the larger size. The tables given in that excellent paper show the great decrease in friction due even to a slight increase in the diameter of the hose.

Of course this change would involve corresponding changes in the size of hydrants and hose fittings, but who that has watched the feeble streams thrown upon a great conflagration has not wished they could be increased in force and volume. Increasing the size of hose for a part of its length at least is no doubt the most economical way in which this result can be secured.

Hydrants in the thickly settled parts of a town should not be over 350 feet apart.

The loss from friction, especially in hose of the present size, is so great, that a good head at the hydrant or steamer is soon lost in forcing the water required for a good fire stream through a few hundred feet of ordinary hose. According to Mr. Freeman's tables, the least friction found was 10 pounds per square inch, and the greatest 27 pounds in 100 feet of hose.

Both were 2½ inches in diameter, the former being solid rubber, with "the interior free from ridges, and was intended to be as smooth as rubber could be made." The latter was unlined linen hose.

When it is considered that even with the best hose, such as is referred to above, and which is probably better than that found in most fire departments, the loss is 50 pounds for 500 feet of hose, we see the advantage of short lines.

Mr. Freeman gives 45 pounds at the base of the play-pipe as the proper pressure to discharge 250 gallons per minute through a 1⅛-inch smooth nozzle, and reckons it as a "good ordinary fire stream."

To obtain the same results with 500 feet of the best rubber hose would require 95 pounds at the hydrant or steamer. If the hose were such that there was a loss of 20 pounds in a 100 feet to produce a stream of the same efficiency would require a pressure of 145 pounds at the hydrant or steamer. All of which goes to show that good fire streams are dependent on short lines of smooth hose.

Hydrants should be set, if possible, just off the supply main, or else there should be a gate on the hydrant branch, which can be closed whenever it is necessary to repair the hydrant.

A saving in the cost of specials can be made by taking the hydrants off the smaller side lines near the main, and this will not increase the friction loss to any extent. The gate shutting off this branch line in connection with others beyond shuts off the hydrant without shutting off the pumping or supply main.

Location of the Pipes in the Streets.—There ought to be more uniformity in regard to the portion of the street in which the pipe is laid. The writer's practice has been to lay the pipes on the north or east side, and about one-third of the width of the street away from the street line.

There is apt to be more sun on those sides of the street in winter, and probably the frost goes to a less depth. This rule cannot always be followed, but as a general thing it is a good one. The center ought to be left for the sewer, if one has not already been built. The south or west side can be used for the gas pipe.

Sometimes the water pipes are laid from one side to another to avoid ledge or boulders. This is not good practice, and the man who follows with another system of pipes will not be happy.

Mr. Diven, in his excellent paper read at St. Louis last year, has spoken of the necessity of complete records of the location of all pipes, gates, branches, etc. The writer has adopted a method which has given excellent satisfaction on several works. The sketches are made in heavy India ink lines on tracing cloth within a rectangle 7¼ inches by 6 inches, with a margin of ½ inch on the side for binding. The sheet of tracing cloth might be 2 feet by 3 feet, containing 18 pages or rectangles.

Black India ink lines mark the boundaries of these rectangles and surround the outside. One or more sketches can be put on one space, but plenty of room should be allowed to make everything, and especially the figures, plain and intelligible.

A blue print is then made, and is cut up by following the division and outside lines.

This makes all the pages exactly the same size. For a small sum a bookbinder will bind them in substantial covers.

The advantage of this method is, that after the tracings are made, any number of blue prints can easily be taken, and if a book is lost, the original is still left. A complete alphabetical index, also made on tracing cloth, from which to take blue prints, makes it very easy to find any desired gate or branch.

A number of these books can be made, and one given to the Superintendent, one to each Water Commissioner, and one to the Town or City Clerk, to keep as a record.

Weight of Cast-Iron Pipe.—Much has been said and written on this subject, but there are two considerations which must be borne in mind in determining the required weight or thickness, and which make it difficult to depend much on theory. One is the fact that pipes must have a certain thickness to stand transportation, and the other is deterioration of pipes from corrosion or other causes. The latter is probably slight, but an accurate knowledge of it can only be obtained by many years' experience.

Much useful information could be obtained by the careful testing of old pipes, which have been in the ground many years. The bursting pressure, weight and thickness should be obtained. The comparison of the weight and thickness with those the pipe possessed when laid would furnish interesting data. If the bursting weight of a similar pipe from the original lot had been taken, this again would furnish interesting and useful knowledge.

For ordinary heads, not over 175 feet, the following weights of pipe will be found satisfactory.

4 inch	20 pounds per foot.
6 "	30 " "
8 "	45 " "
10 "	62 " "
12 "	80 " "

Taking into account the rough handling pipe is likely to receive in transportation, and the fact that it will certainly be no stronger, as successive years go by, the above weights are about right.

Bells and Joint Room.—Bells should be 3 inches deep for 4 and 6-inch, and 3½ inches for 8, 10 and 12-inch pipe. The joint room for the above sizes, should be about ⅜-inch.

Curves.—Curves can easily be laid to a radius of 300 feet, with straight pipe. By occasionally cutting a pipe and using a sleeve, the writer has laid 12-inch pipe on a curve of 80-feet radius. The pressure at the point is 90 pounds per square inch, and there have been no leaks, although the pipe has been laid nearly five years.

Tees or Y's.—Tees or right-angle branches are better than Y's in many localities, even though the angle in the streets differs considerably from a right angle. By putting the tee in at just the right place an easy curve can be made of short bell pieces, which often accumulate, and the pipe brought on to the proper side of the street. If the branch is from the force main, and is between the pump and the reservoir, the resistance to the passage of the water will be the same, whether the water is coming from the pump or from the reservoir.

Water and Sewer Pipes not to Interfere.—Especial attention ought to be given to the fact that if a sewerage system should be established in the future, manholes will be necessary at the street intersections, and as it is necessary to make the sewers straight from manhole to manhole, the required space should be left for them and the sewer pipe. This is especially true where there is much rock excavation.

Service Pipes.—Lead is no doubt the most durable, but there is a prejudice against it in some minds which makes the use of some good substitute desirable. Plain wrought-iron pipe, lined with pure cement, makes a service pipe which is very durable, does not fill up with rust, is capable of being bent to some extent, and is cheap. The cost of lining an inch pipe with cement, so as to make it three-quarters of an inch in diameter, need not be over one cent per foot, The tees and couplings can be lined with lead, or a mixture of lead and tin.

Samples which have been in the ground ten years are as smooth and clean inside as when put in; whereas tarred, enameled or even galvanized iron pipe in many cases would be completely filled with rust.

Gate Boxes.—Various forms of iron boxes are in use which give excellent satisfaction. In country streets they should be set about an inch higher than the street surface, and have a ring of stone paving around them, 12 or 15 inches wide.

ANNUAL REPORTS.

Annual Report of the Board of Water Commissioners of the City of Manchester [N. H.], for the fiscal year ending December 31, 1889.

This brief report of the Commissioners is accompanied by that of the Superintendent, Charles K. Walker, which gives the details. There were 676,135,583 gallons of water pumped during the year, and pumping expenses and repairs amounted to $4,429. There were 10,183 feet of cast-iron mains laid during the year, nearly all 6-inch, of which a part was to replace cement-lined sheet iron pipe. There were 15 hydrants set, making 441 in all, and 139 service pipes added, making 3,226 in all. There were 106 meters set during the year, making 951 in all. The total amount charged to construction account during the year was $30,232, and to current expense $17,006. The receipts were $86,700, including $52,381 for water by rate, and $33,596 for water by meter.

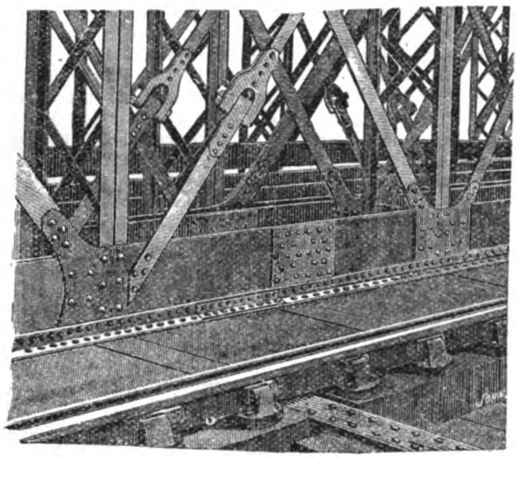
* From a paper entitled, "Our Experience with Artesian Wells," presented by J. T. Lakin, Superintendent of the Rockford, Ill., Water-Works, at the Chicago meeting of the American Water-Works Association, May 20-23.

† From a paper by F. L. Fuller, C. E., Boston, Mass., presented at the Chicago meeting, May 20-23, of the American Water-Works Association.

AN ASTONISHING DETAIL OF BRIDGE CONSTRUCTION.

A RECENT issue of the London *Engineer* has the accompanying illustration of construction of the Newark Dyke railroad bridge, which is being rebuilt with lattice girders of 265 feet span, and says that "Fig. 10 shows the gib and cotter connection in counterbraced bars made from flat bars bent round and cut to shape."

Comment is unnecessary. In this country adjustable diagonals are unknown in lattice girders, which for long spans are constructed for special rigidity, and in general have all diagonals of the same compressive strength. Destroying this would apparently be all loss and no gain for the essential characteristic of the bridge. If, however, it was determined to make a riveted bar adjustable, American constructors would probably weld on or upset stub ends and use a sleeve nut, as is customary for some pin connected flat bars.



Here the bent plate is shown ingeniously weak, whichever way of the grain it is cut, and the cotters are distinctly represented as *without fastenings*, held in place only by friction and continuous strain, and not only liable but almost sure to rattle out. The connection plates of the lower chord and diagonals have an amusing resemblance to short-sleeved underwear.

It is to be hoped that details of this kind are not of frequent occurrence in British practice.

NEW METHODS OF INVESTIGATING BRIDGE STRESSES.

To supplement the ordinary superficial inspection of iron bridges in service, M. Firmin Larroque, as appears by a paper published in the Proceedings of the Institution of Civil Engineers, has devised apparatus designed to afford comparisons between the effects produced by the application of the same load to a bridge at different times. Assuming the case of an elementary bridge of a single girder strained by the passage over it of a given rolling load at a certain velocity, he considers the bridge composed of an infinite number of vertical cross sections or laminæ, each of which receives a vibration wave from the passage of the load over every other lamina. These waves may be received by a microphone and transmitted electrically to a telephone. A record taken when the bridge is new may be compared with all future records, and the difference, if any, noted. Such difference would be an indication of deterioration. In order to compare the records they must be lasting; for this purpose the phonograph is used, and this is the key to the system. The author has used three different methods: (1) A string, stretched by a small weight, was passed over a pulley, the spindle of which was fixed to the vibrating body; the string was then carried to a spiral spring, and thence to the diaphragm of a phonograph, the spring being used to lessen the length of the vibration. (2) An india-rubber ball, with a small weight placed upon it, was connected by tubing to a drum, one face of which was the diaphragm of a phonograph; both these methods are of little use when the distance between the phonograph and the vibrating point is great. (3) The vibrations are received by a microphone which transmits them to a telephonograph which registers them, and this method is suitable for any distance. In order that the length of time occupied in noting vibrations may be always exactly the same, a contact forming part of the circuit to the two instruments is placed at each end of the bridge, the first of which is closed by the passing body as it comes upon the bridge, the other opened as it leaves it. For comparison of different records, the author prefers sight to hearing, and, for this purpose, has modified the phonograph as follows: In place of the diaphragm he uses a thin rectangular plate, fixed by one edge, and carrying at the other end a point on one side, and a very small mirror on the other, which latter reflects a ray of light on to a screen. The phonograph, if then made to travel parallel to the screen, produces a luminous zigzag line on it, and, if two instruments are used, and both are made to travel and revolve at the same speed, two records can be compared, or one phonograph may be used in a fixed position, while a sensitised paper is made to travel in front of it in place of the screen. Any number of different tests may then be compared by photography. The author has been able to discover, and to locate, hidden flaws in bridges by the above means, and the whole apparatus may be used for any number of bridges.

MARINE PARK, BOSTON.

AT the eastern extremity of South Boston, and about two miles from Boston proper, there has been laid out a unique pleasure ground, called the Marine Park. The accompanying illustrations show the manner in which it is proposed to complete it, provided permission can be obtained from the United States Government to lay out the Marine Garden on Castle Island, which is now occupied as a military station.

Among other things the Park was designed to furnish a sea beach sweeping around a bay, which might serve as a rendezvous for pleasure boats and a field for aquatic sports, and a pleasure walk and drive back of the beach, from which there might be an extended view of the harbor; also, a pier carried out far enough from the western headland of the bay to open to view two fine expanses of natural scenery not otherwise to be commanded from any public ground in the city, one towards the ocean and the other towards the head of Dorchester Bay. A marine aquarium was also designed to be a prominent feature of the Park.

The pier and pier-head shown in the lower part of the plan have been completed, as described in our issues of January 28, 1888, and September 21, 1889. The pier is of iron, and the pier-head is an artificial island somewhat pear-shaped in plan, built of gravel, with its outer line protected by a sloping wall of ballast and riprap, surmounted by a parapet of cut granite. In the center a circular wall has been built to serve as a foundation for the proposed building shown in Fig. 2.

PIER HEAD BUILDING, AT MARINE PARK, BOSTON
FIG. 2

ACTION OF GYPSUM ON MORTAR.

THE destructive action of gypsum on mortar in construction is illustrated by the condition of the exterior talus of the curtain of a stone wall in Paris, described by *La Semaine des Constructeurs*, which was built of blocks of mill stone faced with calcareous stones containing a large proportion of pieces of gypsum. It appeared on examination that the wall was disintegrated in many places to a thickness of 4 inches, and when taken down for renewal in 1886 the mortar had changed from white to rose color, and was found hard and white between two calcareous stones, but incoherent between a calcareous and a gypsum stone, especially nearest the gypsum, and between two gypsum stones, entirely pulverized. Furthermore, in the last case the powdered mortar was unctuous to the touch, burned the skin slightly as if partially unslacked, and, when retempered and made into bricks, would set in the open air, but remained plastic when immersed in water. The deduction seemed warranted that the presence of the gypsum had destroyed the strength of the mortar, or at least hastened its decomposition.

An analysis of samples of mortar taken from between two calcareous stones, from between two gypsum stones, and from between a calcareous and a gypsum stone, respectively, showed in all cases alike about 50 per cent. of sand, 20 per cent. of lime, 20 per cent. of shrinkage, or "loss by fire," and small amounts of alumina, peroxyde of iron, magnesium and insoluble residue, and a marked variation in the amount of sulphuric acid, which was, respectively, 0.40, 2.05 and 3.75 per cent. The composition of the gypsum stone was determined to be, lime 32, sulphuric acid $45\frac{8}{10}$, insoluble residue 1, alumina and peroxyde of iron $\frac{1}{10}$ per cent., a trace of magnesium and a shrinkage of $21\frac{7}{10}$ per cent.

The relation of the variable quantity of sulphuric to the decomposition of the mortar is thus explained by Captain Dolot: "Mortars exposed to irregular action of sea water are affected by the dissolved sulphate of magnesium in the water which acts on free lime, its alluminate, its sillicate, and in some cases on its double sillicate of lime and alluminum. The magnesium becomes inert, the lime is converted into a hydrate or soluble salt (chlorate or sulphate), or crystallized in mass in sulphate form, and the structure is at length transformed into a dry wall. Probably analogous phenomena occurred in this wall. Water, constantly filtering in and evaporating, attacked the gypsum and resolved it to sulphate of lime, which, every time the moisture diminished, expanded in the interstices of the water, evaporated, and formed crystals, which by their expansion burst the mortar that enveloped them. When the humidity increased these crystals were dissolved, afterwards reforming and breaking other cells, and so on, the mortar thus being mechanically disintegrated slowly but almost continuously.

The color was occasioned by a little hydrated peroxyde of iron, liberated by the sulphate of lime. The unctuousness of the crumbled mortar is attributable to the presence of dissolved sulphate of lime. The bricks hardened in the air because the sulphate of lime contained in them set, but remained pasty under water where the sulphate of lime could not crystallize.

These phenomena can be artificially produced by placing in a glass of water a piece of gypsum in contact with a piece of hard mortar. Experiments were made with mortar from Besse's lime, five months' old, and Portland mortar well set. No action was observed so long as the immersion was total, but allowing the water to evaporate sufficed to cause the formation of crystals of sulphate of lime on the emerging portions, and the cracking of the mortar which finally fell to pieces.

The conclusions point to the prohibition of the use of gypsum stones in constructions exposed to humidity, but if a controlling reason imposes their employment, they should be built exclusively separate in one section by themselves."

A LARGE RAILROAD BRIDGE IN INDIA.

Indian Engineering, in describing the just-completed Chittravati Bridge, between the Kondapuram and Tadpatri stations on the northwest line of the Madras Railway, says:

It is the finest bridge yet built in Southern India, being over half a mile long, divided into 19 openings of 140 feet each from center to center of piers; these are spanned by double-intersection Whipple-Murphy girders, each 139 feet 8 inches long, 20 feet wide, and 17 feet deep, supported on cast-steel fixed and roller bearings at alternate ends; the distance between the center of these or effective span being 136 feet. Each girder weighs 146 tons 12 cwt.; the rails are bolted to longitudinal teak beams, laid on wrought-iron trough rail runners supported by cross girders placed 8 feet apart, and riveted to the lower chords of the main girders, which are connected at top by massive plate overhead struts, riveted to the top flanges.

The 18 piers are each formed of a pair of cast-iron cylinders 12 feet in diameter, placed 18 feet apart. These extend from the bottom rock to within 10 feet of the river surface, where their diameter is reduced to 9 feet by a conical taper piece 7 feet 6 inches high; from this up to their top the cylinders are 9 feet in diameter; above the river surface the pair of 9-foot cylinders forming the pier are joined by massive wrought-iron bracing boxes, firmly bolted thereto and filled with concrete.

Each 12 feet cylinder is formed of rings 6 feet deep, each made up of six segments 1½ inches thick, strengthened by vertical and horizontal internal ribs, all joints are planed or turned, and the segments and rings are joined together by 1¼-inch bolts, a space being left which is calked with iron rust cement to form water and air-tight joints. The metal in the 9-foot diameter cylinders is reduced in thickness to 1¼ inches. The rock of the ancient river bed was found at from 18 feet to 78 feet below the present sandy bed.

At half the piers there was found over the rock a layer of trap boulders often cemented together by kunker, varying in thickness from 6 to 22 feet; sinking the piers through these boulders was by far the most difficult and tedious part of the work, and required 27,988 hours of diver's work; 255 lineal feet of 12 feet cylinders and wells were sunk through these boulders.

One cylinder took eleven and a half months to sink it through 22 feet of large boulders, and the other of the same pier eight and a half months. One of the boulders removed contained 35½ cubic feet or nearly three tons. The foundations of this one pier took as long as all others.

Large loads of rails were used to force the cylinders down aided by the firing of small charges of dynamite in the bottom of the excavation. The largest load used was 1,300 rails or 290 tons.

When sunk and bedded the cylinders were filled with concrete made of one volume English Portland cement, two and a half sand, and six of stone, measured dry, which came to one of mortar to two of stone, mixed wet.

This was lowered through the water by self-acting skips, till a sufficient depth to keep the water out was put in; when this concrete had set the water was pumped out and the rest of the cylinder filled dry, the concrete being carefully rammed in 6 inch layers as deposited.

From river bed to within 2 feet of the top the cylinders were filled with stone masonry in surki mortar, the last 2 feet being of one Portland cement to two sand, on which the cast steel bearings were set.

In erecting the girders they were built on Camber blocks under the shipment joints *laid on the river bed* in the dry season, service bolted and riveted complete; after which they were lifted up bodily by four 60-ton hydraulic jacks placed two at each end.

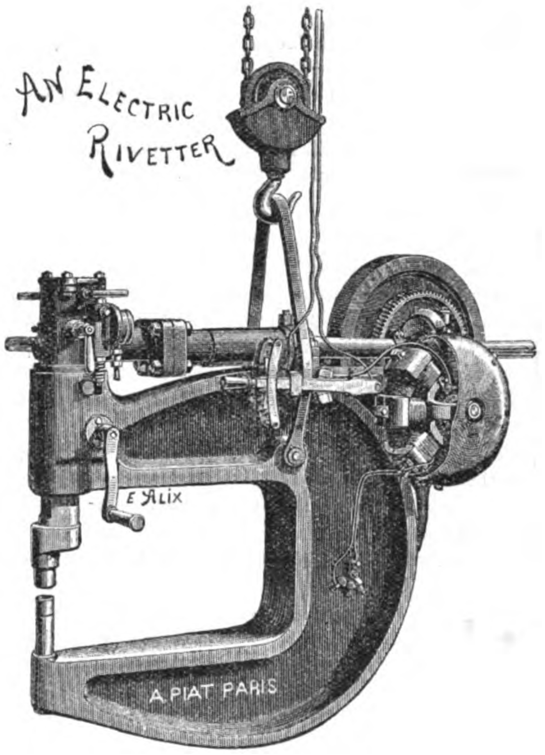
By this system the bulk of the riveting work was done by men standing on the river bed, and the use of all false works and temporary staging avoided.

The bridge was built in a little over 22 months, including interruptions by freshets and the floods of *two* wet seasons.

For a great part of the time 1,200 men a day were employed, and of these only two men were killed, and these by unavoidable accident.

AN ELECTRIC RIVETER.

THIS portable riveter, illustrated in the Paris *Genie Civil*, has been recently designed by A. Piat for general use where riveting is to be done in places supplied with dynamos for electric lighting, etc., and said to be easily driven anywhere that the work requires it and at any distance from the source of power.



THE EFFICIENCY OF AUTOMATIC SPRINKLERS.

IN the course of a discussion on automatic sprinklers at the Cincinnati meeting (May 13–17) of the American Society of Mechanical Engineers, C. J. H. Woodbury said that although the first automatic sprinklers were invented early in the century, yet the production of practical devices and their introduction on a large scale has been limited to the last 12 years.

The efficiency of such devices is shown by a compilation of the fires occurring on property insured by one insurance company, from January 1, 1877, to January 1, 1890. These fires are divided into two classes; the first including those where automatic sprinklers formed a portion of the apparatus in service over the origin of the fire, and the second including those which lacked the service of such apparatus. At 290 automatic sprinkler fires only 122 of which reached sufficient amount to be followed by a claim, the losses amounted to $127,665.44, the average cost of each fire being $433.32. The other losses amounted to $7,388,503.25 at 947 fires, 400 of which were followed by a claim; the average cost of each fire being $7,802.01, or 18 times the average less occurring at fires under automatic sprinklers. It is but fair to say, however, that these figures deal with full automatic sprinkler systems, and from them have been eliminated such instances as where the water was shut off from the automatic sprinklers, or where they were not provided with a proper static supply in the usual manner. An automatic sprinkler system is not different from other mechanical devices in requiring frequent inspection.

But these results were reached by a very few automatic sprinklers, although the whole number of such devices is very great. Mr. Woodbury stated that he had in his possession 165 different forms of automatic sprinklers, most of which would not be reliably operative in case of fire, or they are so constructed as to be especially prone to leakage or to disability by corrosion.

FRENCH FORESTRY DEPARTMENT.*

AT the Paris Exposition the exhibition of the Department of "Eaux et Forets" is made in a special building of its own. The exterior is covered with slabs showing the bark in such a way as to resemble tree trunks and has rustic decoration. This appropriateness of style is a minor illustration of the æsthetic taste which characterizes the French exhibition. Different portions of the interior of the Forestry Building are assigned each to a single kind of tree, and for each kind there is exhibited the surface with the bark on, sections transverse, radial and tangential, and the goods into which it is manufactured; as, for instance, one kind is made into wooden shoes, another into boxes, a third into bottle-stoppers, etc. This simplicity by which facts are made as clear as possible, even to untrained minds, is also very characteristic of the French exhibition; further illustration of it will be found in what I am going on to speak of. Another portion of the Forestry exhibition shows the work of the Department in the mountain regions, the French Alps and Pyrenees, in protecting the steeply sloping territory. Where a mountain side was liable to landslides or avalanches of rock, a series of retaining walls is built, and loose boulders are supported, and the growth of vegetation is started to hold the soil. In valleys which torrents of water have occasionally devastated, some very extensive improvements are made. The injury by flood is not only the washing out of the upper valley, but the overwhelming of arable land in the flatter portion below with the detritus, destroying its fertility, and the cutting off of communication over government roads, which, near the frontier, are important from the military point of view. The cure for these evils is of the nature of substituting for the inclined bed of the stream a series of steps, so that, instead of acquiring such destructive velocity, the water may fall nearly dead from one pool to another. More practically speaking, the fundamental work of protection consists of building dams at short intervals on all the steep parts of the channels. These dams, however, are of several classes; in the upper and smaller channels they are merely little rough stone walls of the simplest character, while on the lower and larger portions of the streams some are fine masonry structures with waste ways, comparable with the best that are built here for water power. It is not uncommon to put a hundred or more dams on a single stream. Besides, the beds of the streams are improved by removing their irregularities and establishing a smooth and approximately uniform cross section, so as to facilitate steadiness of flow. The banks, which may have been denuded, are replanted with whatever is suitable to grow. This work of caring for the whole length of the channels has cost in the aggregate millions of francs; and to an American who is accustomed to seeing mountain streams left in a state of nature, it is very striking, and suggests that in this country it is high time that more general interest were awakened in the preservation of existing forests at least. The most conspicuous part of the exhibition consists of three handsome paintings, such as are called dioramas, giving very natural representations of three of the works as they would look to an actual spectator from a well chosen point of view. They show mountain summits and landscape and possess merit as works of art. In one of the scenes the spectator seems to be looking out of a smithy; in another out of an engineer's shanty fitted up in realistic style. In alcoves adjoining are collected maps on a large scale of the areas drained by the streams, photographs for comparison taken from nearly the same standpoints before and after the execution of the works, and monographs describing the work in detail and giving its cost, also plans and sections, pictures of scenery and full information.

THE water-works report of Mansfield, O., for the 12 months ending April 30, 1889, William Ritter, Superintendent, shows that there were 1,430 feet of 4 and 6-inch mains laid during the year, making 94,345 feet in all; three hydrants added, making 130 in all, and 75 services added. There were 456,562,500 gallons of water pumped during the year, the total cost of fuel was $2,072, the average domestic pressure was 95 to 100 pounds and the fire pressure 100 to 125 pounds, and the total running expenses were $5,914. The amount charged to construction account was $4,067, and the receipts from water rents $8,999.

---

* Some Notes of Foreign Travel, by Fred. Brooks, read before the Boston Society of Civil Engineers, and published in the *Journal of the Association of Engineering Societies*.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department*. Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

TOWNS SEWERED ON THE FRANCHISE PLAN

GEORGE E. WARING, JR., Consulting Engineer, of Newport, R. I., writes: "Referring to your discussion as to franchises for the sewerage of towns by private corporations, it may be of interest to you to consider the inclosed prospectus of a company which had a contract with the city of New Orleans.

The interests of the city seemed to be well guarded, and the cost to householders would have been less than the cost of vault cleaning by the expensive system there in vogue.

The capital for the company could not be raised, at the time the effort was made, because of a lack of faith in the Legislature and Courts of Louisiana on the part of Northern investors—an objection which probably no longer exists."

THE NEW ORLEANS DRAINAGE AND SEWERAGE COMPANY.

The New Orleans Drainage and Sewerage Company offers for subscription $1,000,000 of its capital stock (10,000 shares of $100 each).

The company is organized under the general Incorporation Act of the State of Louisiana as amended by an act approved April 10, 1880. It is incorporated for the period of 99 years, and its charter contains the following provision:

"No stockholder shall ever be held liable or responsible to or through said corporation for its contracts or faults in any further sum than the unpaid balance, if any there be, due on the share or shares owned by him and standing in his name."

The capital of the company is $1,500,000, (which may be increased to $5,000,000.) Of this $500,000 is common stock, which may be issued in payment for services or property. The remainder, now offered for subscription, is preferred stock, the entire proceeds of which are to be applied to construction account.

The preference is as follows:

"The preferred stock shall be entitled to dividends from first profits up to 8 per cent. per annum, by preference over said common stock. If there be in any year profits to be divided over 8 per cent. on the amount of such preferred stock, the same shall be declared as dividends on the common stock, up to 8 per cent. per annum on the same; and if there be in the same year further profits to be divided, the same shall be declared equally and pro rata on both common and preferred stock."

The funds now to be subscribed are to be used for the construction of a complete system of sewerage and soil drainage in the city of New Orleans, on the plan now in operation in Memphis, Tenn.

After a most carful examination of the subject, and on the urgent recommendation of the New Orleans Auxiliary Sanitary Association, and of the Louisiana State Board of Health, of leading engineers and physicians of New Orleans, of the City Engineer, and of a Committee of the Council, sent to Memphis to investigate the system, the Council passed an ordinance (approved by the Mayor April 19, 1881), granting to this company a franchise for the laying of sewers and sub-soil drains for a period of 99 years, subject to the city's right of purchase at appraised valuation at any time after 20 years, and directed the Mayor to make a contract with the company, which binds the city to the above conditions and engages that the city of New Orleans will not adopt any other system of sewerage for a period of 25 years after the execution of the work, say 30 years in all, and that "the city will at all times, by a proper exercise of its police powers and other powers, protect the pipes and other property of the company from obstruction and injury, and will, by every lawful means, promote and enforce the adoption and proper use of the system herein provided, and will at all times, during the term of the said contract, provide and enforce the provisions and prohibitions contained in the second section of this ordinance, or their equivalent, with diligence and in good faith.

By the terms of the contract, as fast as the company's sewers are made ready to receive the drainage of houses, it becomes unlawful for householders along its course to maintain any privy vault, cesspool, surface gutter or other means of disposing of household wastes, except through closets, sinks, drains, etc., connected with the Company's sewers. That is to say, the use of the sewers is compulsory for the entire population, as the facilities are furnished. The company is not required "to accept or furnish an outlet for any drain not of its own construction, nor unless the fixtures used in the house shall have been approved by it; its approval or refusal to approve being subject to the sanction of the State Board of Health, whose decision shall be final, as of safe and proper construction; nor to accept any connection with any property until its owner shall have executed the contract contemplated by Section Second of Act No. 125 of 1880, providing for securing proper compensation to the company by privilege or servitude." By this provision the claims of the company for unpaid sewer rates take precedence of all mortgages and may be collected by summary process.

The rates to be charged vary for dwelling houses according to size, from 85 cents per month to $2 per month. Corresponding rates are fixed for business establishments, hotels, etc. These rates are subject to considerable discounts for payments in advance. If paid annually in advance, the charge for dwelling houses is from $6 to $17 a year.

There are now in New Orleans about 25,000 dwellings, and it is estimated the rates from these will be sufficient to pay 15 per cent. dividends on the cost of the work, beyond operating expenses. There are about 10,000 other buildings.

It is worthy of note that the rates provided to be paid for the removal of all domestic wastes are less than the present cost of compliance with the municipal regulations concerning the emptying of privy vaults alone. Indeed, the scheme on which the company is based has all the advantages enjoyed by companies for furnishing illuminating gas, with the important modification that every member of the community will become, as a matter of sanitary regulation, a patron of the works, while the company has no manufacturing expenses to pay. The city is not now closely built up, and its anticipated early and considerable increase of population will add to the revenue of existing sewers, by occupying vacant lots along the line.

The directors of the company are leading business and professional men of New Orleans, and the entire work is to be under the consulting engineer of the company, Col. George E. Waring, Jr., the originator of the Memphis system of sewerage.

Condition of Subscription.—The first installment, 10 per cent., to be paid on subscribing; and the second installment (5 per cent.,) becomes payable November 15, 1881, and the remainder in installments of not more than 10 per cent. each, and at intervals of not less than 30 days, as called. The 10 per cent. paid on stock subscribed for in excess of allotment will be credited on the next assessment on the alloted shares. Shares will be alloted in proportion to subscriptions in all cases, except that single-share subscriptions in New Orleans will be allowed in full.

During construction, and prior to the earning of dividends, interest on moneys actually advanced will be paid, from revenues received, at the rate of 5 per cent. per annum, and charged to construction account. It is estimated that not more than 65 per cent. of the subscription will be called. Of the dividends declared, 8 per cent., on the amount paid in, will be paid to holders of preferred stock in cash, and the remainder will be credited as the payment, on account of the unpaid subscription on the stock, until the full amount, 100 per cent., shall have been paid up. J. H. OGLESBY, President.

AIR CUSHIONS ON A WATER-MAIN.

"T. B. S.", of New York, writes: "In your reply to 'City Engineer,' under the head of 'Air Cushions on a Water-Main,' page 394, you refer to and explain the disappearance of the air from air chambers. Will you explain how this loss may be compensated for? Would also like your opinion as to the proper sizes of air chambers."

[To renew the air in the chamber without drawing the water from the pump or main a small air pump is often arranged to be worked by hand, or, better, by some moving part of the engine. Sometimes a small air cock is placed on the suction but this should be very carefully looked after, for the admission of too much air, and very little is enough, not only reduces the capacity of the pump by the expansion of the air on the suction stroke, but in a pump without a fly-wheel the sudden compression of the air on the return stroke permits the plunger to acquire undue velocity at the start causing unpleasant and sometimes, perhaps, even dangerous shocks. Another way would be to have an auxiliary chamber connected to the air chamber top and bottom by two pipes with valves, and enough lower than the air-chamber so that when the auxiliary chamber was filled with air, and the valves were opened in the connecting pipes, the air and water in the two chambers would change places, which operation could be repeated as often as necessary. Care should always be taken to so place the air-chamber that any free air in the water current could rise into it and the connection with the air chamber should be equal to the size of the force main.

How large the air chamber should will be depend on the character of the pump and the speed and pressure at which it is run. As the office of the air chamber is to equalize the flow in the force main it is obvious that the more irregular the delivery of the pump the more work the air chamber has to do, and hence the larger it must be. A single-acting pump would therefore require a larger air chamber than a double-acting one of the same capacity, and a duplex or rotary pump less than either, in fact the two latter would hardly need an air chamber at all. A fly-wheel pump would need more air chamber than a direct-acting one, on account of the greater variations in speed of plunger which the fly wheel introduces. Obviously, too, the faster a pump runs the more air chamber it needs, since any pump, if run slow enough, can get along without an air-chamber. The pressure also must be considered, as the only efficient part of the air-chamber is that occupied by the air, and its volume will be inversely as the total pressure. For instance, the same air at 15 pounds pressure, or 30, including atmosphere, will occupy three times the space and give three times as much cushion as it would at a pressure of 75 pounds, or a total of 90 pounds. If air is artificially supplied to the chamber its effective capacity will, of course, be independent of the pressure, which then does not make so much difference, except as the strains on the metal are more severe and their equalization therefore of more importance. The length of the force-main and the average velocity of the water in it should also be considered, since both these things increase the liability to water hammer and the danger resulting from it.

By preparing a diagram showing the relative speed of the pump plunger at different parts of its stroke, or the aggregate speeds if there is more than one plunger, and comparing it with the average speed, an air-chamber can be so proportioned that the variations of pressure in the force main shall not exceed a given amount. Ordinarily the effective capacity of the air-chamber should not be less than twice, and need not be more than four times the displacement of one stroke of one plunger, but it will usually be wise to give the air-chamber the benefit of any doubt, and make it as large as a due regard for economy and other considerations will permit.

Sometimes a stand-pipe is better than an air-chamber for reasons explained on page 346, but it has the disadvantage that it cannot usually be placed so close to the pump, and therefore an air-chamber is commonly used even with a stand-pipe, but it need not be so large in that case.

ANNUAL REPORTS.

MISSISSIPPI RIVER IMPROVEMENT OF NAVIGATION BETWEEN MINNEAPOLIS AND DES MOINES RAPIDS, including improvements at special localities between those points; operating and care of the Des Moines Canal. Officer in charge, Major A. Mackenzie, Corps of Engineers, U. S. A.

The annual reports of Major A. Mackenzie, Corps of Engineers, U. S. A., of the work under his charge for the year ending June 30, 1889, constitute appendix A A, of the report of the Chief of Engineers, who first mentions that $549,600 has been expended altogether for snag boat service on the upper Mississippi, and that as a result accidents and damage from snags, wrecks and such obstructions have become very rare. He also notes the completion, for $125,000, of a dry dock 400 feet long and 100 feet wide at the Des Moines Rapids Canal.

Major Mackenzie gives the work of the snag boats more in detail, and also gives abstracts of proposals received for various items of shore protection and dam construction. The lowest bids for loose stone in place in lots of from 14,000 to 22,000 cubic yards varied in different places from $1.19 to $1.54 per cubic yard, and for brush from 40 to 50 cents per cubic yard. The highest prices were $1.95 and 85 cents respectively.

Assistant Engineer C. W. Durham, complains of the dumping in the river of large quantities of refuse from the city of St. Paul. It is said that 500 tons of refuse are dumped into the river every day from Minneapolis, which has a crematory of 200 tons daily capacity, and if St. Paul contributes 500 more it would be sufficient in 25 years, taking a ton of refuse to equal one cubic yard, to completely fill the river bed to one foot above low water for a distance of 30 miles.

The materials for river improvement works cost, rock on barges 62½ to 64½ cents per cubic yard; brush on barges 25 to 28 cents per cubic yard; material in place costs from $1.14 to $1.23 per cubic yard, or exclusive of plant charge, 79 to 86 cents, and, exclusive also of general superintendence and office expenses, 66 to 72 cents; cost of material on barge was from 33 to 45 cents, and of towing and putting in material 27 to 34 cents.

Gen. T. L. Casey, Chief of Engineers, indorses the recommendation of Major Mackenzie, that the rapids at Rock Island be improved for a distance of some 13 miles at a cost of $330,000, in preference to constructing a lateral canal for that distance, at a cost of $4,000,000, which he does not think the present requirements of navigation will warrant. A map of the rapids and details of the proposed improvements are given.

SECOND ANNUAL REPORT OF THE BOARD OF WATER COMMISSIONERS OF LITTLE FALLS, N. Y., 1889.

The greater part of the report is given up to a detailed financial statement for the year ended January 1, 1890. The report of the engineer, Stephen E. Babcock, refers to the work of maintaining and extending the system, water vents, etc., and gives also a record of fires for the year. The annual water rates for 1890–91, as adopted by the Board of Water Commissioners, are published in the concluding pages of the pamphlet.

ST. AUGUSTINE, FLA., has decided to establish a garbage cremator, to be managed by a contractor.

DOMESTIC PLVMBING HEATING LIGHTING & VENTILATION ENGINEERING

PLUMBING DETAILS IN THE MECHANICS' BANK BUILDING.

THIS building, at 33 Wall Street, New York City, just completed, is designed for an office building and to accommodate the Mechanics' Bank, which occupies all of the first floor. The building is about 30 feet front by 70 deep and is nine stories high, exclusive of basement and janitor's apartments on the roof.

The plumbing includes the following fixtures: one basement toilet room for the bank employees, containing 4 water-closet sinks, 3 urinals and 5 wash basins. One private toilet room on the first floor for the bank officers, containing 1 water-closet, 1 bath-tub, 1 wash-basin and 1 urinal. One general toilet room on the ninth floor that contains 8 water-closets, 3 urinals and 1 wash-basin. On the ninth floor there is a ladies' toilet room containing 3 water-closets and 1 wash-basin.

The eighth floor has a small toilet room with one wash-basin, and there is a slop sink on every floor above the basement, and on each floor from the second to the seventh inclusive there is a toilet room, 1 water-closet, 1 wash-basin and 1 urinal. The janitor's apartments contain 1 bath-tub, 1 water-closet, 1 wash-basin, 1 pantry sink, 1 kitchen sink and 13 tray laundry tubs. In the basement engine room are the hot and cold water distribution drums, a drip sink and a water-closet.

Figure 1 shows the distribution system in the basement near the pumps. Y is the cold and Z is the hot water drum, each about 2 by 5 feet, made of galvanized iron and supported by the gas-pipe table X X, etc., set in the footing of the foundation walls. The drum Z contains a 2½-inch pipe *a*, supplied with live or exhaust steam through a pipe S.

The arrangement of the pipe *a* is similar to that made by Byrne & Tucker for the Mills and the Duncan Buildings in New York, described, respectively, on p. 203, Vol. VI, and p. 296, Vol. VIII. The pipe S passes through a stuffing-box *b*, and is screwed into a wrought-iron head plate that is welded into the top of the pipe *a*. The return steam-pipe *s* is screwed into a hollow rivet that is cast on the bottom of the cap *c* that is screwed into the bottom of the boiler and tapped to receive the pipe *a*. The stuffing-box permits the pipe S to slide back and forth through it with the expansion movement, which is taken up by the spring of the horizontal branch S S. The large pipe *a* is used instead of the usual steam coil to prevent noise when the full head of steam is turned on, and to heat the water rapidly. Cold water under tank pressure is received through the 2-inch* pipe C and supplied to the distributing drums through branches W and W. Q is a 1½-inch pipe supplying water under street pressure. Ordinarily its valve V is closed, but by opening it the drums Y and Z may be filled directly from the street mains, or the basement fixtures, which are branched from Q, may be supplied from the tank.

Cold water is distributed through the building from the drum Y through the 1½-inch pipe D and the 1-inch pipes E, F and G to different lines of wash-basins, and through the 1-inch pipes N, O and P to the various flushing cisterns.

Hot water is delivered from the drum Z through the ¾-inch pipe R to the engine room sink and through the 1½-inch pipe A to all the slop sinks and to the officers' toilet room. B is a ¾-inch return circulation pipe, H is a 2-inch safe waste from the roof tank and I, J, K and M are 1-inch safe wastes from the toilet rooms. L is a 2-inch delivery pipe from the pumps to the roof tank. V is a drip-pipe through which all the rising lines may be drained by opening their cocks T T, etc. The drums Y and Z may also be drained into it through their emptying pipes U, U.

Figure 2 shows the roof tank, built of ¼-inch iron plate and 2 by 2-inch angles with ⅝-inch tie rods A A, and Tee bar stiffeners B B, etc. The tank is filled through the 2-inch pump pipe G, overflows directly upon the tiled roof through the 3-inch pipe D and may be emptied also directly upon the roof through the 1½-inch pipe E. F is a 3-inch fire line with hose couplings on every floor C is the 2-inch supply pipe to the distributing drums Y and Z (Fig. 1), H is a 1½-inch supply pipe direct to the janitor's apartments, and I is a 2-inch supply pipe direct to the ninth floor toilet room. K, K, K are vent-pipes to facilitate the discharge of all the water in the supply lines C, H and I, after their valves J J J are closed. L is a vent pipe from the hot-water drum Z, Fig. 1. M is a float whose chain N operates the index of the tank gauge in the pump room. The float M is made of a butler's pantry copper sink with a sheet of copper tightly soldered over the top.

Figure 3 is a diagram of the ninth floor toilet room which is about 12 feet wide by 22 long, and contains 8 water-closet sinks, 3 urinals and 1 wash-basin. It has a tiled floor, oil finished wood-work, and white marble wainscoat and panels A A, etc. The irregular shape of the room made it necessary to arrange the urinals as shown, two of them, U U placed back to back opposite the entrance and screened by a 7-foot marble slab B. C is a marble safe.

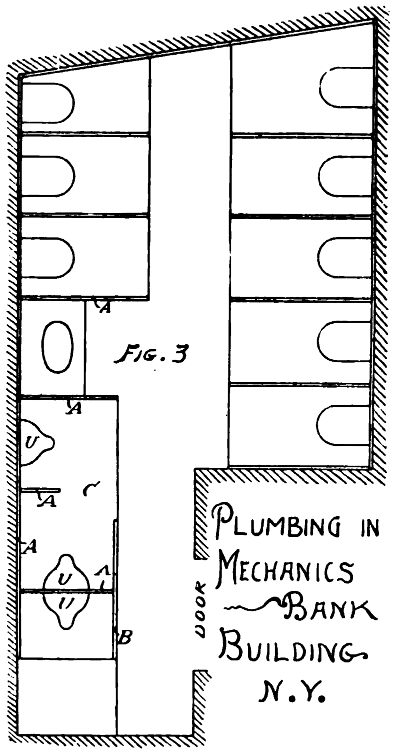


Figure 4 shows the suspended horizontal boiler in the janitor's kitchen. Cold water is received through the pipe C and hot water through the pipe H; the branch B supplies the kitchen sink and the branch A supplies the laundry tubs, bath-room, etc. The janitor's bath-room is finished with unusual elegance, having marble wash-basin table, royal porcelain bath-tub, ivory finished water-closet and nickel-plated exposed brass pipes. The floor and wainscoat are finished with white and tinted ceramic tiles.

Figure 5 shows the drip-sink S in the engine room. It is supported on pieces of 1-inch gas pipe A A, leaded into the footing of the foundation wall over which it is set so as not to occupy much floor space. An adjacent water-closet

---

* The sizes given for pipes are correct but the sketch is not drawn to scale.

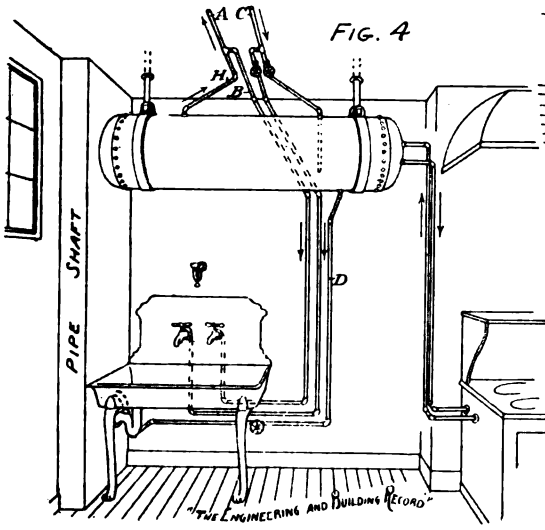

FIG. 4

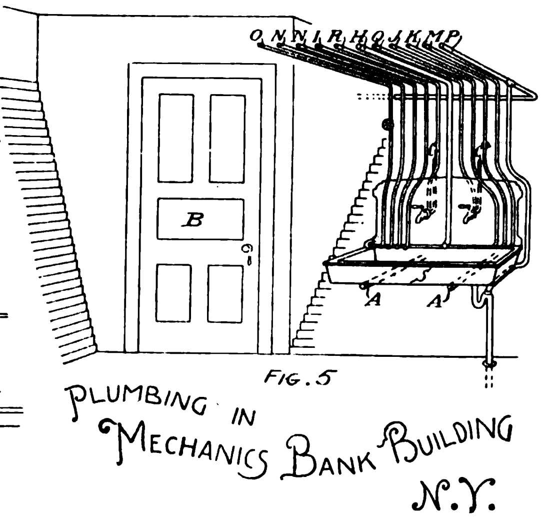

FIG. 5

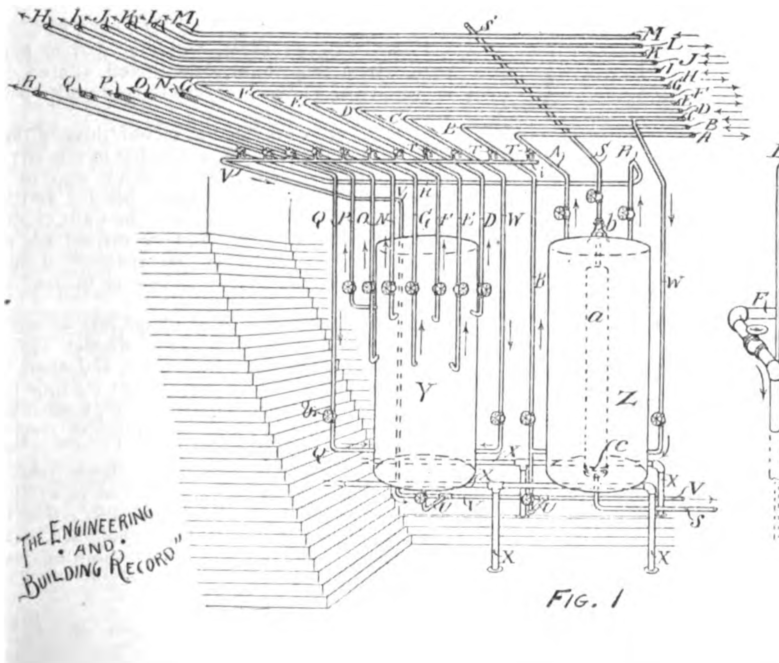

FIG. 1

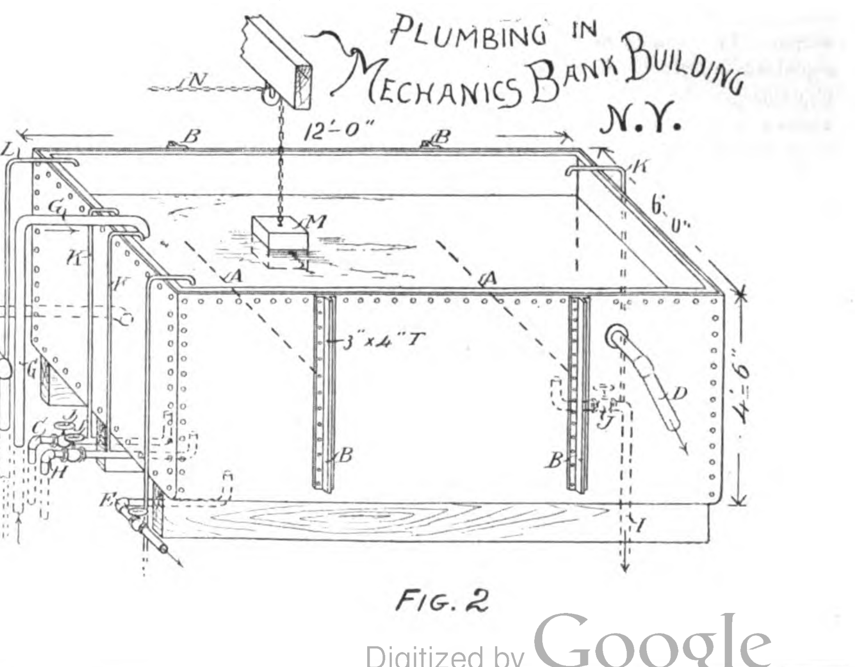

FIG. 2

at B is also arranged so as to be convenient for the firemen, etc., and not take up unnecessary floor space. Q is the drip-pipe from the roof tank safe, and H, I, J, K and M are drip-pipes from toilet room safe wastes. R is the hot and Q the cold supply (Fig. 1), N N are safe wastes, P is a trap vent-pipe and O is the drip-pipe from the steam radiators.

C. W. Clinton, of New York, was the architect of this building, and Byrne & Tucker, also of New York, did the plumbing.

COMPARATIVE TESTS OF RADIATORS.

At the Cincinnati meeting of the American Society of Mechanical Engineers, Charles E. Emery directed attention to the fact that it is possible, in testing many devices, to state correctly the actual results obtained in detail when, on account of the methods employed, the tests do not show the true comparative value of competing devices.

For instance, experts know, what house owners and many steam-fitters do not, that the efficiency of a radiator depends upon the freedom with which air can circulate over the radiating surfaces; so engineers can be found who will make a careful test of a client's radiator with a given surface distributed over considerable length; for instance, with only two rows of small pipes, and test in comparison an opponent's wide, short radiator arranged, say, to put the same surfaces in pipes four or five rows deep. The long, thin radiator will condense more water every time, and if the engineer in his report makes a correct drawing of the radiators tested, so that on the face of the report he does not appear to deceive the public, but is careful not to mention the principle involved, the client has an opportunity of extolling the merits of his particular radiator in comparison with his opponent's, and to gain a commercial advantage not entirely warranted by the actual relative values of the goods themselves.

RECEIVING TANKS ON STEAM HEATING SYSTEMS.

The return of drips in heating systems that take steam directly from low pressure boilers may be easily managed, but when high pressures must be maintained in the boilers for furnishing power and the steam for heating has to be passed through reducing valves new elements of difficulty come up for consideration. The *Locomotive*, in a recent issue, gave illustrations of receiving tanks applied to such systems.

It appears that a certain heating plant was giving much trouble from pounding and rattling. The returns entered the receiving tank through a pipe which passed horizontally through the head near the bottom of the tank. The supply for the pump was taken from the bottom through another pipe at right angles to the return pipe. An escape pipe was placed in the top of the tank to relieve the pressure. Cold water was also admitted, when necessary, through another pipe which entered the top of the tank. The cause of the trouble was at once apparent. The return pipe entering below the level of the water in the tank, a considerable portion of the steam that was returned was condensed at once upon striking the cold water, and the noise so produced was communicated through the piping to every one of the buildings heated. The pump also would occasionally refuse to work, although it was placed properly below the tank level so that the water would flow into it of its own weight. The trouble here was that the return pipe, as explained, entered close by and at right angles to the pipe through which the pump was fed, so that the steam which entered through the return, along with the water of condensation, broke the current in the suction pipe.

To remedy the trouble the return pipe was arranged to enter the tank at the top, discharging the water of condensation upon the surface of the water already in the tank. The escape pipe was removed so that the vapor collecting over the water could not pass off. By this removal of the escape pipe a great saving of heat, and therefore of fuel, was effected. When the pressure from the accumulating vapor in the tank equalled that in the heating system, the water of condensation flowed into the tank only as fast as it accumulated in the pipes. The connections and returns could thus be kept flooded so that all noise in the pipes was prevented.

In referring to this point further the *Locomotive* remarks that when all the pipes to the radiating surfaces are of good size, and the pressure throughout the heating system is uniform, it is well to run a small pipe from the steam main to the tank so as to prevent the water from being blown out of the return pipe. This will make the flooding of the connections certain, and the small pipe may be very easily arranged so as to remove the drip from the main steam pipe, as well as to keep up the pressure in the tank. A drip valve should be placed at the lowest point of the return pipe for draining it when it is not in use, and one should also be placed on the receiver to remove air and prevent an air bond in first starting up the system.

Where there are some radiators so nearly on a level with the water in the tank that they will not return their drips freely through the return pipe entering the upper part of the tank, it is often advantageous to allow such radiators to return their water through a separate pipe which enters the tank 8 or 10 inches or a foot lower than the surface of the water in the upper return pipe. This will give the ill-conditioned radiators the advantage of a correspondingly less static pressure to return against, and will equalize the circulation all over the buildings.

Notes and Queries

on Domestic Engineering.

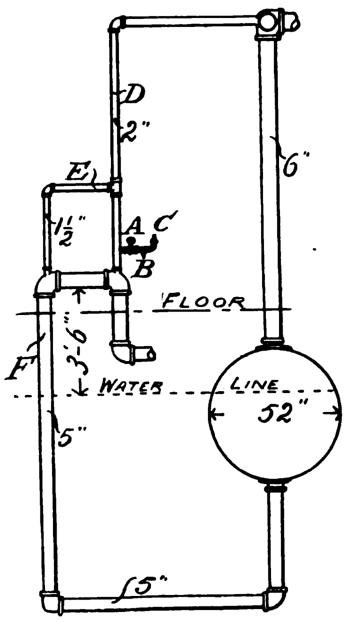
Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

TROUBLE WITH A STEAM HEATING PLANT

Guy Tilden, architect of Canton, O., writes: "I inclose you herewith a blue print showing the arrangement of the artificial water line of steam heating job in this city, which is giving some trouble. The job contains about 2,000 feet of direct radiation, is a two-pipe job, with separate return from each radiator which connect with the main return. There are straight-way stop valves in the main supply and main return but no check valve in the return.

The trouble is that the water syphons out of the returns with considerable force, which takes about half a minute, and then everything is quiet for 15 or 20 minutes, then it will syphon again, finishing with snapping, cracking and a little pounding, then all is quiet again.

The 2-inch pipe D we had put on first and, thinking that this choked when syphoning began, I had the 1½-inch pipe E put on. This helped it some, but only a little. Then I had the pipe E disconnected from D, and increased to 2 inches and run direct to the boiler. This helped still more. I also had a 1½-inch pipe connected with the return at F and run direct to the boiler, but this did no good at all. I also had a ½-inch pipe and stop valve connected at A, a compression gauge cock at B and a check valve at C, and found that when syphonage occurred with eight pounds pressure on the boiler the check would momentarily open, and if we opened the gauge cock B, water and steam, principally water, would flow through at a great rate."



[We have known of trouble similar to yours in an apparatus arranged with an artificial water-line. The cause of it was never satisfactorily explained, but it was remedied by using a swing check valve and stop valve in the pipe D as close to the top of the syphon as it was possible to place it. The check valve, of course, should open from the main steam pipe towards the return pipe. The stop valve was used simply to vary the size of the passage through the pipe D and is probably not essential. It, however, may save further trouble to put it in when the alteration is made for the check valve. We believe that the engineer in charge found the contrivance to work best when nearly closed. It will be necessary to alter the pipe D above the branch E so as to use a horizontal check-valve. This, however, is a matter of detail which any fitter should understand.]

NATIONAL PLUMBERS' ASSOCIATION MEETING.

The eighth annual convention of the National Master Plumbers' Association will be held at Denver, Col., June 17, 18 and 19.

ADVANTAGE OF PLUMBING AND VACCINATION LAWS.

A. R. Carter, Secretary of the Health Department of Baltimore, Md., in sending information regarding plumbing regulations adds the following suggestive information regarding the advantage to the city of a compulsory vaccination law and a plumbing law · "From January 1 to December 31, 1882, 2,825 cases of small-pox were reported in Baltimore, 617 of the number being removed to the Quarantine Hospital, 1,496 had been vaccinated and 1,329 exhibited no signs of vaccination; 551 died in the city and 188 at the Quarantine Hospital. From January 1, 1883, to July 7 of the same year, no cases being reported after the later date, 2,114 cases were reported, of which number 395 were removed to the Quarantine Hospital, where there were 109 cases remaining from 1882, making a total of 504 cases. Of the 2,114 cases reported 1,363 had been vaccinated and 751 exhibited no signs of vaccination. Six hundred and thirty three deaths occurred in the city and 353 at the hospital, making a grand total of 4,939 cases, of which number 2,859 had been vaccinated and 2,080 exhibited no signs of vaccination, 1,729 having died during the epidemic, a very large majority being unvaccinated.

During the period from January 1, 1882, to July 7, 1883, our corps of vaccine physicians, made 300,000 vaccinations, besides many thousand by family physicians. Only bovine virus was used by our vaccine physicians. One death only during the entire period was reported by the attending physician as being caused by vaccination, the decedent being a child, during the month of March, 1883.

The cost of the epidemic to our municipal government was $190,000 in expenses, 1,725 lives, and millions of dollars to the trade of our city, nearly all of which could have been saved by a compulsory vaccination law and a timely appropriation of $50,000; but the warnings of the Health Department were unheeded, until October, 1882, when our prayers were answered by the "City Fathers," the law was enacted, appropriations were made, extra vaccine physicians appointed, the law enforced in all cases, and by July 7, 1883, the disease was stamped out entirely, and not a case has originated in our city since that date. One case was brought here in 1884 and one in 1886.

October 22, 1883, an ordinance to provide for the inspection of soil, waste and drain pipes, and all other sanitary plumbing was approved by our Mayor, which went into effect January 1, 1884. From 1830 to 1883, inclusive, a period of 54 years, scarlet fever had averaged 226 deaths, whilst for the past six years, 1884–1889, inclusive, the average has been 59 deaths. In 1830 the population was 81,000, and there were 149 deaths; in 1889, population 500,343, 71 deaths. Diphtheria for seven years prior to ordinance averaged 469 deaths; for the past six years, 1884–1889, inclusive, the average has been 145 deaths. In fact all zymotic diseases have exhibited a marked diminution since the enactment and enforcement of the two good ordinances.

YONKERS BUILDING ORDINANCE.

The following is the building ordinance of Yonkers, N. Y., adopted October 28, 1889:

I. No wall, structure, building, part or parts thereof shall hereafter be built, constructed, altered or repaired in the city of Yonkers, except in conformity with the provisions of these regulations.

II. Except as provided in section three of these regulations, all buildings hereafter erected in this city shall have all walls constructed of stone, brick, iron, or other hard incombustible material, properly bonded and solidly put together, with close joints; and the walls of all buildings shall be built to a line and be carried up plumb and straight, and the several component parts of said building shall be built and constructed in such manner as is herein provided.

III. Frame or wooden buildings may be erected in this city, provided that such frame or wooden buildings shall not exceed three stories in height, and shall not have a frontage of over 45 feet, and that at the time of the erection of said frame or wooden buildings an open space of 3 feet intervenes between the building so erected and the nearest adjacent building.

IV. The basement walls of dwelling houses not over 36 feet in height, and not over 25 feet in width, shall not be less than 12 inches thick if of brick. The other walls (not including foundation walls) shall not be less than 8 inches thick; but no party wall shall be less than 12 inches thick. The walls of dwelling houses over 36 feet in height, and not over 50 feet in height, shall not be less than 12 inches thick above the foundation walls, except the top story, the wall of which may be 8 inches.

V. No wall of any building now erected or hereafter to be built or erected, shall be cut off below or altered, without permission so to do having been first obtained from the Inspector of Buildings. Every temporary support placed under any structure, wall, girder or beam, during the erection, finishing, alteration or repairing of any building or structure, or any part thereof, shall be of sufficient strength to safely carry the load to be placed thereon. The walls of every building, during the erection or alteration, shall be strongly braced from the beams of each story, until the building is inclosed, and the roof tier of beams shall be strongly braced to the beams of the story below until the floors in the said building are laid.

VI. In no case shall the wall or walls of any building be carried up more than two stories in advance of any other wall except the front wall.

VII. In all buildings every floor shall be of sufficient strength in all its parts to bear safely upon every superficial foot of its surface 75 pounds; and if used as a place of public assembly 120 pounds; and if used as a store, factory, warehouse, or for any other manufacturing or commercial purpose, from 150 pounds and upwards; and every floor shall be of sufficient strength to bear safely the weights aforesaid, in addition to the weights of the materials of which the floor is composed; and every column, post or other vertical support shall be of sufficient strength to bear safely the weight of the portion of each and every floor depending upon it for support, in addition to the weight required as above to be supported safely upon said portions of said floor.

VIII. The planking and sheathing of the roof of every building other than frame, erected or built as aforesaid, shall in no case be extended across the front, rear, side, end or party-wall thereof unless filled in between with brick and mortar level to the top of the beam.

IX. No building already erected or hereafter to be built in said city shall be raised, altered or built upon in such manner, that were such building wholly built or constructed after the passage of this act, it would be in violation of any of the provisions of these regulations. Before any building shall be enlarged, raised, altered or built upon the same shall be first examined by the Inspector of Buildings to ascertain if the building or buildings are in good and safe condition to be enlarged, raised, altered or built upon, and no such building shall be enlarged, raised, altered or built upon until after such examination shall have been made and a decision thereon rendered by the Inspector of Buildings; and the decision of said inspector after such examination shall be made without delay.

X. Before the erection, construction or alteration of any building or part of any building in the city of Yonkers is commenced, the owner or his agent or architect shall submit to the Inspector of Buildings a detailed statement, in writing, of the specifications, and a full and complete copy of the plans of such proposed work, which shall be accompanied with a statement in writing, giving the full name and residence (street and number) of the owner, or of each of the owners of said building or proposed building. Such statement may be made by the agent or architect of the person or persons hereinbefore required to make the same, said statement and detailed statement and copy of the plans shall be kept on file in the office of the Inspector of Buildings, and the erection, construction or alteration of said buildings, or any part thereof, shall not be commenced or proceeded with until said statements and plans shall have been so filed and approved by the Inspector of Buildings. Ordinary repairs may be made without notice to the Inspector, but such repairs shall not be construed to include the cutting away of any stone or brick wall, or any portion thereof, the removal or cutting of any beams or supports, or the removal, change or closing of any staircase.

XI. The drainage and plumbing of all buildings, both public and private, hereafter erected in the city of Yonkers, shall be erected in accordance with plans previously approved in writing by the Board of Health or its authorized agent. Suitable drawings and descriptions of the said plumbing and drainage shall in each case be submitted and placed on file in the Health Department.

XII. The Inspector of Buildings shall attend at his office each day between the hours of 11 o'clock A. M. and 12 o'clock M.

XIII. The Inspector shall keep a constant supervision of all buildings in the course of erection, and report in writing to the Mayor any violation of the law of the State or of any of these regulations, and the Mayor is authorized upon such report to take such legal proceedings as shall be necessary to enforce compliance with the law of the State and the regulations of the Common Council and of the Inspector of Buildings.

XIV. Any person aggrieved at the decision of the Inspector of Buildings may appeal, in writing, to the Mayor, who shall decide the question involved, and report at the next meeting of the Common Council his action in the premises. And the Common Council shall have power to review the action of the Mayor, and may overrule the same by a two-thirds vote.

XV. The Inspector of Buildings shall examine all buildings deemed by him to be unsafe in any particular, or reported to him to be unsafe, and within 24 hours after such examination deliver duplicate reports of the condition of said buildings, one to the Mayor and one to the Common Council, by leaving the same with the City Clerk.

XVI. Fire escapes shall be erected upon such buildings whenever, and in such manner as shall be required by the Inspector of buildings.

XVII. These regulations shall take effect December 1, 1889.

Novelties.

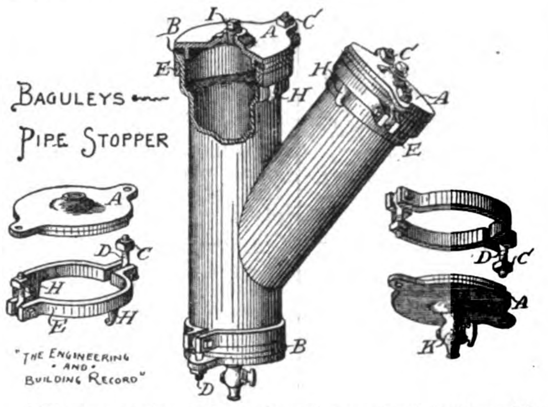
Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course, be understood that the selection does not imply endorsement.

BAGULEY'S PIPE STOPPER.

THIS device consists of a cast-iron disk, A, that can be tightly screwed to the end of a pipe by nuts C C of the bolts D D attached to the malleable iron collar E, which may be clamped to the pipe above the bead of either end. B is a rubber gasket. Hub clamps have also the hooks H H, that catch the shoulder and are sufficient to hold it without bearing on the bead. Every cover plate has a boss in the center, tapped to receive either a plug I or a stop-cock K.



This stopper is made in five sizes, 2 to 6 inch, and is specially designed to close waste and soil pipes, etc., for the application of a pressure test. It is claimed that it is easily applied, economical and durable, that it takes up so little room that it can be used in close places where there is very little clearance, etc., and that it has been tested to 130 pounds steam pressure.

This device has been patented by William Baguley, 504 Park Avenue, New York City.

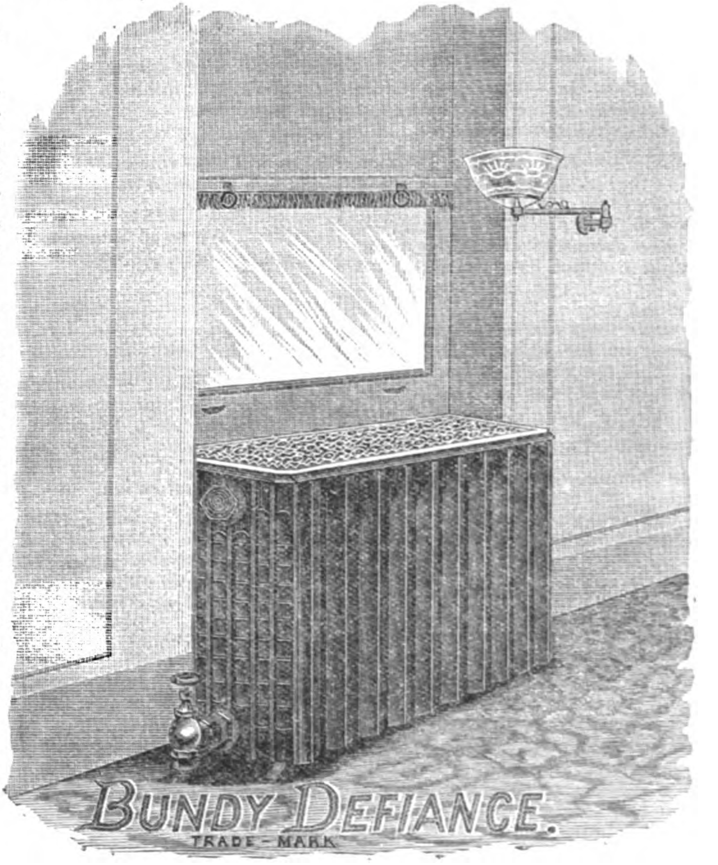
IMPROVED STEAM AND HOT WATER RADIATOR.

THE accompanying cut shows the latest modification of one of the A. A. Griffing Iron Company's steam and hot water radiators recently brought out at their works, Jersey City, N. J., and called the "Bundy Defiance."

The special features of it are its adaptation for use under windows, in recesses, or wherever a low radiator is required, and also its compactness, giving a large surface in a limited space. In placing this radiator under windows, the window sill often serves as a top finish, or a marble slab resting on brackets over the radiator can be used.

There are two sizes of "Defiance" sections, 8 by 13 and 11 by 18 inches, respectively, the first figure representing the width of the sections or radiators, while the last shows the height. Its total height can be increased when the radiator is set on legs, and here a special feature is observed in the great variety of heights in which the legs are furnished. They can be had ½, 1, 1½, 2, 2½, 3, 3½, 4, 4½, 5 and 5½ inches high, so that the radiators can be furnished in different heights, varying by half inches, from 13½ to 23½ inches. When no height is specified in ordering, the 1-inch legs are always shipped.

The larger section has 7 square feet of heating surface, the smaller one 4, and in either case each section increases the length of the radiator 4 inches. All sections are interchangeable.



NATIONAL CONVENTION OF BUILDING INSPECTORS.

PURSUANT to general desire on the part of a large number of the building inspectors of the United States, a convention is called to meet at the Grand Pacific Hotel in Chicago, on Wednesday, June 18, 1890, at 2 o'clock P. M., for the purpose of organizing a National Association of Building Inspectors, appointing committees, and mapping out our work, after which we will adjourn to meet at some future time and place to be at that time decided upon. A general invitation is extended to all inspectors of buildings in the United States, with an earnest desire that you be present at our initial meeting.

Every city that has now, or contemplates having in the near future, building laws, should be represented.

Committee of Inspectors of Buildings: J. M. Hazen, Minneapolis, Minn.; Gates A. Johnson, St. Paul, Minn.; George C. Whitlock, Omaha, Neb.; J. M. Dunphy, Chicago, Ill.; T. J. Brady, New York City; Arthur Bates, Milwaukee, Wis; E. W. Simpson, Detroit, Mich.; Frank H. Jackson, Denver, Col.; Emil G. Bueckert, Cincinnati, O.; Spencer B. Hopkins, Providence, R. I.; Roy McDonald, Louisville, Ky.; L. W. Hanson, Portland, Me.; G. T. Woodward, Lowell, Mass.; J. Theodore Oster, Baltimore, Md.; John S. Damrell, Boston, Mass.; George Wharton, Philadelphia, Penn.; M. A. Lytel, St. Joseph, Mo. May 31, 1890.

TRADE PUBLICATIONS.

THE COMBINATION GAS MACHINE.

AN attractive catalogue, entitled "Light for Evening Hours," just issued by the Detroit Heating and Lighting Company, of Detroit, Mich., sets forth in a pleasing manner the advantages and claims to general recognition of the "Combination' gas machine. The latter, as may be known, is intended for factory or other buildings, in city or country, of such extent as to warrant the establishment of an independent lighting plant. The catalogue contains illustrations of the machine itself, and of a number of buildings where it is said to be in successful operation. The last two pages of the catalogue are devoted to the Bolton hot-water boiler, made by the Company, a sectional perspective and general descriptive particulars being given.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

CONTRACTING INTELLIGENCE

Persons who make any use of the information they find in these columns we trust will not omit to mention The Engineering & Building Record as the source

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." *Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.*

For works for which proposals are requested see also the "Proposal Columns," pages i-ii-x-15.

WATER.

For Additional Water Items see Proposal Columns.

Santa Ana, Cal. — City Clerk Edward Tedford writes: "The Board of Trustees of this city advertised for plans and specifications for water-works. They accepted plans and specification for a stand-pipe system May 23, the system not to cost over $50,000. Now they will call an election to vote bonds, and if the bonds are carried will be ready to accept bids on the plans and specifications they have adopted. We will know in about six weeks."

Richmond, Ky.—City Clerk J. E. Greenleaf writes: "We have signed contract with Richmond Water-Works Company to build and operate a system of water-works. Work to begin within 60 days from May 7, and to be completed within 12 months from that date."

Rochester, N. Y.—J. Nelson Tubbs, Chief Engineer, writes: "It is pretty well settled that an additional supply of 15,000,000,000 gallons per day from Hemlock and Canadice lakes will be provided in the near future. Actual work will not probably be commenced until 1891. The cost will be nearly $2,000,000."

Humboldt, Neb.—City Clerk E. W. Elwell writes: "There is some talk of establishing water-works in our city, but as yet have taken no steps in regard to the matter further than to have plans, specifications and estimate drawn; we have not received them from the engineer yet. Do not know what the result will be till after the election."

Owosso, Mich.—The City Clerk here writes: "June 9th we vote to bond the city for $20,000, run 20 years at 5 per cent., to complete our water-works already begun."

Walthowville, Ga.—The Town Clerk at this place contradicts the published report that water-works were to be established.

Hinton, W. Va.—Recorder J. T. Hoffman writes: "The Hinton Water-Works Company has been granted a charter with a capital stock of $50,000 and a privilege of increase. The stock is on the market, and being taken up rapidly. A contract has been submitted by the town of Hinton to this company for approval on 90 days. The company will pump the water from the Greenbrier River into a reservoir on the side hill at 100 feet elevation. It is the desire of the town to have the work in as soon as possible."

Shelton, Wash.—This place is to have a system of water-works.

Falls of Rough, Ky.—Town Clerk L. Green writes: "There has not been anything done yet towards establishing water-works here, and I hardly think will be very soon."

Brooklyn, N. Y.—The Aldermanic Committee on Water and Drainage has decided to report to the Board for adoption the budget for the Water Department proper during the year ending April 30, 1891. The total amount is $762,368.

Antwerp, N. Y.—The citizens of this village, at the special election May 29, voted in favor of appropriating the sum of $10,000 for putting in a system of water-works. The Water Commissioners will at once perfect plans for putting in the works.

Salt Lake City, Utah.—A proposition from the Utah Water Company to purchase the water-works plant now owned by the city has been presented to the City Council and referred to the Committee on Water-Works.

Zanesville, O.—The City Council, May 26, passed a resolution declaring it necessary to issue bonds to the amount of $50,000 for the improvemement of the water-works of the city by the laying of a 30-inch pipe from the reservoir to the foot of Market street, to supply the heart of the city with more water.

Marblehead, Mass.—The following proposals for laying cast-iron water pipes, rock excavation, etc., were opened April 29, by the Marblehead Water Board. F. L. Fuller, Engineer:

J. Erwin Hillpot, 1719 Sydenham Street, Philadelphia, $21,586.26; John C. Coates, 31 Exchange Street, Boston, $25,670.82; E Eugene Eglee, Flushing, N. Y., $26.816.48; N. J. Dean, 10 South Street, Salem, $27,393.58; Gore, Little & Co., Cambridgeport, $27,705.59; Frederick E. Show, Providence, R. I., $27.869.87; Geo. W. Mantle, New York, $29,064.87; J. T. Langford, Boston, $29,364.75; J. J. Newman, Providence, R. I., $30,431.50; T. William Harris & Co., New York, $31,764.18; F. D. Mayo, Lynn, $33,610.83; Ferris & Halliday, Jersey City, N. J., $35,068-66; Dennis O'Connell, Dorchester, $35,103.39. The contract was awarded to N. J. Dean, Salem Mass.

Lebanon, O.—Charles B. Stevens, of this place, proposes to supply the town with water on the franchise plan. His proposition provides for six miles and a half of cast-iron pipe, two horizontal duplex compound engines, and the town to rent 65 hydrants for a period of 30 years, at an annual rental of $3,250.

Bentonville, Ark. — Mayor W. D. Mauck writes: "The matter of water-works has been postponed until October."

Norristown, Pa —The managers of the Pottstown Gas and Water Company has awarded the contracts for their new reservoir above town, with pumping station, water mains, etc., which will cost about $125,000. There were eight bidders for the reservoir, seven for the pipe laying and for the pumping machinery. The contract for laying over three miles of water mains was awarded to Howard E. Ahrens, of Reading. The reservoir and pumping station contracts were deferred for the present. The company has awarded the contract for manufacturing 1,500 tons 20, 24 and 30-inch iron pipe for the water mains to the Mellert Foundry and Machine Company, of Reading.

Cleveland, O.—It is proposed to extend the water-works tunnel two miles further under the Lake. Address City Engineer Force for particulars.

Woodstown, N. J.—The people of this place will soon vote on the question of establishing a system of water-works.

Trenton, Tenn.—Mayor Oppenheimer writes: "We voted May 29 to build a system of water-works, the cost not to exceed $20,000.

Lynn, Mass.—The Common Council has allowed an appropriation of 75,000 to be used in the Water-works Department.

Lowell, Mass.— Among the improvements proposed for the water-works system at this place are a filtering plant and new pumping engines. The estimated cost of the engines is $40,000. City Engineer Evans can furnish information.

Mohawk, N. Y.—Proposals will soon be wanted for the construction of a system of water-works at this place. For details address Valentine Brown, Chairman Water-works Committee.

Woburn, Mass.—The City Council has voted to recommend the construction of another supply main to the reservoir, at an estimated cost of $0,000.

Davenport, Iowa.—The water company has decided to put in a filtration plant of six million gallon daily capacity. The issuance of bonds to cover this expenditure and for an extension of mains is under consideration.

Hamburg, N. Y.—Extension and improvements will be made to the plant of the Hamburg Water and Electric Light Company at this place.

Calvert, Tex.—The water mains at this place are to be extended. For particulars address L. T. Fuller, Water-works Superintendent.

Huntington, Ind.—John W. Hill, C. E., of Cincinnati, O., has been engaged to prepare plans, etc., and to superintend the construction of a system of water-works at this place.

Circleville, O.—Extensions will be made to the water mains of this place.

Oconto, Wis.—This place is to have a system of water-works at an estimated cost of $125,000. H. J. Hilbert, C. E., of Milwaukee, Wis., can furnish details.

Xenia, O.—An extension to the water mains will undoubtedly be made the coming season. The superintendent of the water-works is G. F. Cooper.

St. Marys, O.—This place is to have a system of water-works. For particulars address John W. Hill, C. E., Cincinnati, O.

Oshkosh, Wis.—The water-works system at this place is to be remodeled. John W. Hill, of Cincinnati, O., is preparing the plans.

Denver, Col.—The Denver Water-Works Company has awarded a contract for two 15,000,000 gallon triple expansion pumping engines to E. P. Allis & Co., of Milwaukee, at a cost of $170,000.

Bel Air, Md.—The contract for the construction of a system of water-works at this place, has been awarded to James H. Harlow & Co., of Pittsburg, Pa.

Millvale, Pa.—James H. Harlow & Co., of Pittsburg, Pa., have been awarded the contract for constructing a system of water-works at this place.

Water-Works.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: St. Paul, Minn.; Brooklyn, N. Y.; Columbus, O.; Waycross, Ga.; New Rochelle, N. Y.; Ogden, Utah; Denver, Col.; Binghamton, N. Y.; Cedar Rapids, Iowa; Nebraska City, Neb.; East Liverpool, O.; Ottawa; Fargo, N. Dak.; St. Louis, Mo.; Providence, R. I.; Milwaukee, Wis.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

Dayton, O.—At a meeting of the City Council, the resolution declaring it necessary to sewer the city was reconsidered and referred to the Committee on Drains and Sewers,

Brunswick, Ga.—An election will be held here June 7, on the question of issuing $300,000 sewerage bonds.

Clinton, Iowa.—The City Engineer is preparing plans, etc., for the construction of numerous stoneware sewer-pipe extensions.

Port Huron, Mich.—Numerous tile sewers are to be constructed at this place. Address Alderman O'Sullivan, the Chairman of the Sewer Committee, as above.

Norristown, Pa.—Sewer mains are to be constructed in numerous streets of this city. Address the City Clerk, as above.

Williamsport, Pa.—A bill has passed the City Council which authorizes the Highway and Sewer Committee to employ Carroll Philip Bassett, C. E., to prepare plans, specifications, etc., for a system of sewers and appurtenances for this place. For particulars, address Mayor Keller, as above.

Boston, Mass.—Our correspondent writes: "Referring to the proposals for building Sections A and B, Metropolitan Sewer, Henry C. Ayer, Chester, Pa., has been notified that his bid has been accepted and to comply with the conditions of the contract by filing bonds, etc., but no award will be made until said bonds are accepted by the Board of Commissioners. This matter will probably rest as it is, until the meeting of the Board on Saturday next."

Orange, Mass.—The contract for building the new sewer system at this place, has been awarded to Lucian A. Taylor, of Boston, for $62,954.

Springfield, Mo.—On May 27, the citizens of this place voted in favor of issuing bonds in the sum of $150,000 for constructing a separate sewerage system. The plans, which were furnished by George E. Waring, call for over 19 miles of mains.

Troy, N. Y.—Numerous sewer extensions have been ordered by the Public Improvement Commission. Commissioner Thompson can furnish information.

Wilmington, Del.—The Directors of the Street and Sewer Department, have voted the sum of $27,000 for continuing work on the intercepting sewer branches. President Farra can give details.

Kingston, Jamaica.—The Legislature of the Island of Jamaica has adopted Colonel Waring's plans for the sewerage of Kingston, and the work is to be carried out by Messrs. Waring, Chapman & Farquhar, of Newport, R. I., in preparation for the International Exposition to be held in Kingston in 1891.

Columbus, O.—The Board of Public Works of this city has engaged Col. George E. Waring as consulting engineer to revise the plans for an intercepting sewer for that city, and to report on a general scheme of interior sewerage.

Boston, Mass.—The following proposals for the construction of Section A, main sewer, were opened May 28 by the Metropolitan Sewerage Commission: Edward F. Brigham, Cambridge, $90,835; Moulton Mahoney Trumbull, Lawrence, $89,862.50; John Cavanagh & Co., Boston, $87,565; William H. Ward, Lowell, $84,990; Harry P. Nawn, Boston, $81,470; Perkins & White, Boston, $81,435; Everson & Liddle, Yonkers, N. Y., $72,273.75; National Construction Company, Boston, $70,681; Orrin P. Roberts, Cambridge, $65,794.25; Charles Linnehan, Cambridgeport, $64,083.75; Henry C. Eyre, Chester, Pa., $63,150.

Boston, Mass.—The following proposals for the construction of Section B, main sewer, Boston and Brookline, were opened May 28 by the Metropolitan Sewerage Commission: Henry C. Eyre, Chester, Pa., $41,745; Orrin P. Roberts, Cambridge, Mass., $47,928.45; Everson & Liddle, Yonkers, N. Y., $50,950.25; National Construction Company, Boston, $51,640.50; Edw. F. Brigham, Cambridge, Mass., $54,813.75; William H. Ward, Lowell, Mass., $60,609.

Springfield, Mo.—The citizens of this place, on May 27, voted on a proposition to issue $150,000 bonds for constructing a separate sewerage system, according to the plans of George E. Waring, with about 19 miles of mains. The proposition was carried.

North Tonawanda, N. Y.—The following bids for the construction of about six miles of sewers were received by T. E. Warner, Village Clerk, May 19: E. H. Rogers, Jr., Tonawanda, $110,935.15; J. M. Smith, Buffalo, $101,762.60; Franklin & Olson, Buffalo, $90,919.30; A. D. McConnell, Buffalo, $71,471.77; McGregor & Green, Buffalo, $67,601.99; George B. Allen, Buffalo, $64,953. The contract was awarded to A. D. McConnell at $71,471.77.

Parkersburg, W. Va. — J. S. A. Farrow, City Engineer, writes: "Our city expects to lay 2½ or 3 miles of sewers and 40,000 yards of brick pavement, which will be let, as soon as I can complete profiles, plans, etc."

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

Milwaukee, Wis.—Contract for superstructure for Michigan Street draw-bridge has been awarded to the Milwaukee Bridge and Iron Works, at $14.955.

Wheeling, W. Va.—Plans for the Main Street bridge are to be prepared by F. O. Dodge. Estimated cost of the structure, $90,000.

Birmingham, Ala.—Reports say that this city will again advertise for bids for building the 21st Street bridge.

Fort Worth, Tex.—It is proposed to take immediate steps towards repairing the damaged bridge over the Trinity River, at Main Street. Mayor Fraser can furnish information.

St. Louis, Mo.—The Skinka Construction Company, which received the contract for the masonry on the new bridge to be built over the River des Peres, at Broadway, has failed to comply with the terms of the contract, and will forfeit the contract. The estimated cost of the work was about $16,000. The work will probably be readvertised.

Cleveland, O.—City Engineer Force will make an effort to secure two or three new bridges over the river as soon as possible. One of the smaller bridges has already been pronounced unsafe.

York, Canada.—The Dominion Parliament has appropriated $30,000 towards the construction of an iron bridge over the Grand River, at this place.

Terre Haute, Ind.—The following bids for the construction of a wooden viaduct were received by George H. Simpson, Engineer, May 30: Lafayette Bridge Co., Lafayette, Ind., $4,489.15; Pittsburg Bridge Co., Pittsburg, Pa., $6,200; Missouri Bridge Co., Leavenworth, Kan., $5,249; Wrought Iron Bridge Co., Canton, O., $5,902; R. C. Thompson & Co., Terre Haute, Ind., $5,593.

Cheyenne, Wyo.—Frank Dana, City Clerk, writes: "Our viaduct contract has not been let yet, but will be shortly."

Chicago, Ill.—The following bids for the erection of a swing bridge at Northwestern Avenue were received by the City Engineer, May 25: King Iron and Bridge Co., $14,950; Chicago Bridge and Iron Works, $14,115; Schaler & Shinglaw, $14,930; Bruder & Seifert, $14,000; Lane Bridge and Iron Works, $17,387; Wrought Iron Bridge Co., $15,644.

Minneapolis, Minn—The County Commissioners have received bids for the substructure of the Cedar Avenue bridge as follows: Ring & Tobin, $18,626.99; E. F. Comstock & Co., $18,399.42; W. D. Van Norman, $15,966.55; Minnesota Lake Stone Company, $17,879.61. A bid by R. M. Douglas & Co. was withdrawn, because of its excess over other bids.

The following bids for the iron work of the bridge were received. Wisconsin Iron and Bridge Company, $15,246; S. M. Hewitt, $14,974; King Iron Bridge Company, $15,764; Wrought Iron Bridge Company, $15,200; Clinton Bridge Company, $15,465; Olaff Hoff, $16,100; Chicago Bridge and Iron Company, $15,645; A. Y. Bayne & Co., $15,520; Milwaukee Bridge and Iron Company, $15,300.

Baltimore, Md.—A bill to appropriate $80,455 for the completion of the Light Street bridge, has been favorably reported to the City Council.

Bridges.—See our Proposal Columns for information regarding bridge construction at the following places: Cincinnati, O,; Columbus, O.; Trenton, N. J.; Reading, Pa.; Lamar's Mill, Ga.; Mitchell, Dak.; Boston, Mass.; Lynchburg, Va.; Oil City, Pa.; Eureka, Col.; Alder Point, Cal.

NEW DEPOTS.

Rockville, Conn.—A new depot is to be erected at this place by the New York and New England Railroad Co.

Havelock, Neb.—A depot, together with shops, etc., will be erected here at an estimated cost of $300,000.

STREET-WORK AND PAVING.

Clinton, Iowa.—The City Council has instructed the City Engineer to prepare plans, specifications and estimates for about 20,000 square yards of vitrified brick or cypress block pavement, to be contracted for, for Fourth Street.

Gloucester, Mass.—The sum of $10,000 has been appropriated by the City Council for paving East Main Street.

Lima, O.—The officials of this place have authorized the improvement of numerous streets. Details can be had by addressing J. V. Smiley, as above.

Lynn, Mass.—The sum of $125,000 has been appropriated by the Common Council for street improvements.

Lyndhurst, N. J.—The Union Township Committee has issued a call for an election on June 10, to decide whether the town should be bonded for $42,500, the money to be used for macadamizing streets.

Elizabeth, N. J.—The paving of numerous streets of this city is being agitated. Particulars can be had by addressing Mayor Rankin, as above.

Newport, Ky.—The property owners on Tenth Street propose to have the street improved by grading, paving, etc.

Troy, N. Y.—The Public Improvement Commission is making efforts to establish a boulevard in this city. For details address Commissioner Murry, of the Commission, as above.

Tiffin, O.—Considerable paving is to be done at this place. For particulars address John McCartney, Chairman of the Street Committee, as above.

Valparaiso, Ind.—A stone highway, 11 miles in length, is to be constructed from this place to Chesterton. It is to be 20 feet wide and 14 inches deep. Address Jerome Carter, as above, for particulars.

Readers of **THE ENGINEERING AND BUILDING RECORD** interested in the Contracting News Department of that paper are respectfully requested to examine those columns every week, and advise the Editor of any item which they may find that, in their judgment, is of no value to any one other than the person mentioned.

GAS AND ELECTRIC-LIGHTING.

Gordon, Pa.—This place is to have electric lights, at an estimated outlay of $10,000. Hon. D. D. Phillips can furnish particulars.

Washington, D. C.—A charter has been granted the Volta Electric Light and Power Company, for the purpose of introducing and supplying light and motive power for private dwellings, mercantile establishments and street vehicles. The secretary is H. K. Simpson.

Fredonia, N. Y.—The question of establishing an electric lighting plant here, to cost, estimated, $10,000, is to be settled at a public election to be held at an early day.

Rutland, Vt.—The electric light company of this place is to increase its plant.

Huntington, Ark.—The Huntington Cotton Company of this place will establish a 750 incandescent isolated electric light plant.

St. Joseph, Mo.—This place is to have electric lights; $500,000 is to be invested. Address O. M. Spence, as above.

Penn Yan, N. Y.—This place has appropriated the sum of $1,500 for electric lighting purposes.

Grafton, W. Va.—The Globe Contract Company has closed a contract with the Grafton Electric Light, Heat and Power Company of this city, consisting of 25 arc lights and 500 incandescent plant, installed complete for the sum of $11,000.

Denver, Col—The Portable Electric Light and Power Company has been incorporated at this place. Capital stock, $1,500,000. Henry R. Wolcott can be addressed.

Brunswick, Ga.—It is probable that an electric lighting plant will be erected at this place by the Brunswick Light and Water Company.

Anderson, S. C.—The Anderson Electric Light and Power Company has been incorporated here with a capital stock of $10,000. John F. Roddy, of Rock Hill, can furnish particulars.

Albany, N. Y.—The Erie and Niagara Electric Light Company has been incorporated here. Capital stock, $30,000.

Medina, N. Y.—The Syracuse Electric Construction Co. has been awarded the contract for lighting this village with 41 electric lights, which will be operated until midnight, at a cost of $60 per light. The work of putting in the plant will begin at once.

Rockford, Mich.—This town will have an electric plant.

Holyoke, Mass.—The Holyoke Electric Light Company will establish a plant here to cost $10,000. Address F. A. Wyman, president, as above.

Columbus, O.—The Board of Public Works will take steps to secure a new service for lighting the city.

Blacksburg, S. C.—The Blacksburg Land and Improvement Co, will erect an electric light plant here.

Atlantic City, N. J. The following proposals for gas and electric street lighting were opened at a recent meeting of the City Council: Atlantic City Gas and Water Company will light Atlantic, Arctic and Pacific Avenues, each with 23 arc lights or more, at the rate of $91.25 per lamp for the year; Thomas Grimwood will light Atlantic Avenue with arc lights for $164.25 per light per year, and Pacific and Arctic Avenues for $142.35 per light per year. For furnishing the gas lights the only bid was from the Atlantic City Gas and Water Company, agreeing to furnish the lights for $18 per light per year. The contract for both the gas and electric lighting was awarded to the Atlantic City Gas and Water Company.

Chicago, Ill.—The Fort Dearborn Light and Power Company has been incorporated here. Capital stock, 25,000. Incorporators, A. L. Baker, E. F. Bunyan, and others.

Yazoo, Miss.—City Clerk E. J. Pomsine, writes: "The chairman of Committee on Street Lighting, Mr. Charles A. Collins, has been instructed by the Board of Mayor and Aldermen of Yazoo City, to correspond with different electric light companies, to ascertain probable cost of lighting the city with arc lamps, and no doubt that a proposition for water-works to be run in connection with the lights would be favorably entertained."

Chicago, Ill.—The Worrall Electric Construction Company has been incorporated here, with a capital stock of $500,000, to construct and maintain electric plants. Incorporators, E. Gaylord, M. J. Frost and C. Y. White.

Electric Railways.—New electric railways will be established, and improvements will be made to those already built, at the following places: Beatrice, Neb,; Flushing, N. Y.; Milford, Mass.; Hopedale, Mass.; Holyoke, Mass.; Newburyport, Mass.

GOVERNMENT WORK.

Camden, N. J.—Synopsis of bids for erection and completion of the U. S. Post-Office, Custom House, etc., here (except heating apparatus):

	Amount per specification.	Amount, if faced with stone instead of brick.	Amount to be added if oak is substituted for white pine.	Amount to be added if American plate glass, ¼-inch thick, is used instead of sheet glass.
Wm. Gray & Son, Philadelphia, Pa	$71,413.00	$83,333.00	$1,597	$1,897
R. C. Ballinger & Co., Philadelphia, Pa	72,761.50	87,475 75	4,139	1,100
Robt. S Johnston, Philadelphia, Pa		88,489.00	3,625	1,050
J. E. & A. L. Pennock, Philadelphia, Pa	73,400.00	99 400.00	1,100	1,200
James Bradley, Philadelphia, Pa	73,769.00	97,524.00	3 449	4,449
D. J. Curtis, Spokane, Mo	70,000.00	78,000.00	6,000	2,000
Darling Bros., Worcester, Mass	67,000.00	87,000.00	4,000	1,200
Campbell & Wood, Ithaca, N. Y	93,000.00	98,500 00	2,400	850
Wm. Leverus	97,725.00	113,865.00	2,485	1,340

Washington, D. C.—The following proposals for the work named were opened on the given dates by the Supervising Architect of the Treasury Department:

Fort Smith, Ark.—Iron vault doors for the United States Court House and Post Office at this place, opened June 3. Bidders: National Safe and Lock Company, $345; Mosler Bank Safe Company, $525; Hall's Safe and Lock Company, $570.

Denver, Col.—Brick and terra cotta floor arches, wall furring, partitions, column covering, etc., for the United States Court House and Post Office at this place, opened May 31. Bidders: Wright Fire-Proof Company, Chicago, Ill., $20,786.60; Thomas P, Lee, Chicago, Ill., $16,064; Pioneer Fire-Proof Construction Co., Chicago, Ill., 21,000; Tobias Johnson, $31,833.

*INDUSTRIAL.

Philadelphia, Pa.—The Board of Port Wardens is considering the question of extensions to Pier 30, of the Philadelphia Warehousing and Cold Storage Company.

Xenia, O.—A brick rope walk, to cost over $50,000, will be built here. Eli Millen and Judge E. Munger are interested.

PROPOSALS.

(Continued from page x.)

Notice to Contractors.

SEALED PROPOSALS WILL BE RECEIVED by the Board of Directors of the North Hudson Driving Park Association, at their office, No. 113 Hudson Street, HOBOKEN, N. J., until 7.30 P. M., June 12, for **GRADING** the infield of the Guttenberg Race Track at North Bergen, N. J. Plans and specifications can be seen, and all information obtained at the office of Messrs. BEYER & McCANN, Civil Engineers and Architects, Hudson Place, Hoboken. 1

JUNE 4, 1890.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P.M. on the 28th day of June, 1890, for all the **LABOR AND MATERIALS** required in the erection and completion of the U. S. Court-House and Post-Office building at TEXARKANA, ARK.-TEX. (heating apparatus and approaches not included), in accordance with the drawings and specification, copies of which may be had on application at this office or the office of the Superintendent. Each bid must be accompanied by a certified check for $500. The Department will reject all bids received after the time fixed for opening the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be sealed and indorsed "Proposal for the erection and completion (except heating apparatus and approaches) of the U. S. Court-House and Post-Office building at Texarkana, Ark.-Tex.," and addressed to JAS. H. WINDRIM, Supervising Architect. 2

SEWERS, St. Paul, Minn.—Proposals are wanted until June 9, for constructing sewers in certain streets at this place. Address J. T. Kerker, Clerk Board of Public Works, as above.

SEWERS, Nebraska City, Neb.—Proposals are wanted until June 20, for the construction of a vitrified clay pipe sewer. Address A. F. Mines, City Engineer, as above.

MACADAMIZING, Westminster, Md.—Proposals are wanted, no date specified, for macadamizing about five miles of roads. Address F. K. New, Mayor, as above.

ROADS, Elizabeth, N. J.—Proposals are wanted until June 19, for the improvement of certain roads in this vicinity. Address F. A. Dunham, County Engineer, as above.

PAVING, Columbus, O.—Proposals are wanted until June 11, for improving certain streets by grading, paving, etc., Address F. M. Seuter, Clerk Board of Public Works, as above.

SEWERS, Columbus, O.—Proposals are wanted until June 11, for constructing brick and pipe sewers. Address Board of Public Works, as above.

PIER, New York City.—Proposals are wanted until June 20, for the construction of numerous piers. Address the Department of Docks, Pier A, N. R., as above.

ELECTRIC LIGHTING, Milwaukee, Wis.—Proposals are wanted until July 1, for furnishing, erecting and maintaining 300 or more electric lights, for a term of 3 years. Address Fred. F. Wilde, Deputy Comptroller, as above.

SCHOOL, Peru, Ind.—Proposals are wanted until June 17, for the erection of a brick school building at this place. Address C. E. Emsviler, Secretary School Board, as above.

PAVING, ETC., Des Moines, Iowa.—Proposals are wanted until June 18, for paving certain streets. Address the Board of Public Works, as above.

PUMPING MACHINERY, East Liverpool, O.—Proposals are wanted until June 25, for furnishing additional pumping machinery. Address East Liverpool Water-Works, as above.

BRIDGE, Mitchell, Dak.—Proposals are wanted until July 17, for erecting a bridge at this place. Address R. Robinson, as above.

PAVING, Bradford, Pa.—Proposals are wanted until June 16, for paving certain streets at this place with vitrified brick. Address James A. Lindsey, City Clerk, as above.

BRIDGE, Pembina, N. Dak.—Proposals are wanted until July 8, for the erection of a bridge over the Tongue at this place. Address Mr. Kabernagle Auditor, as above.

STREET WORK, Springfield, O.—Proposals are wanted until June 26, for paving with brick or asphalt certain streets at this place. Address W. H. Linn, City Engineer, as above.

BRIDGE, Pennigton, N. J.—Proposals are wanted until June 23, for the erection of a high truss wrought iron bridge over Jacobs Creek, on the road leading from Pennington to Titusville. Address John O. Ege, as above.

PROPOSALS.

BRIDGE, Forsyth, Ga.—Proposals are wanted until June 17, for the construction of a bridge over the Towaliga River, at Lamar's Mill. Address J. A. Daniel, as above.

SEWERS, Binghamton, N. Y. — Proposals are wanted until June 16, for constructing sewers, drains, etc., in certain streets at this place. Address W. J. Flanigan, City Clerk, as above.

LIGHTING, Camden, N. J.—Proposals are wanted until June 23, for lighting the streets of this city for a term of three years. Address City Clerk, as above.

WATER WORKS, Fargo, Dak.—Proposals are wanted until July 7, for constructing a complete system of water works at this place. Address A. O. Rupert, City Auditor, as above.

SEWERS, Cedar Rapids, Iowa.—Proposals are wanted until June 16, for constructing sewers at this place. Address A. St. Clair Smith, Chairman Committee on Sewers, as above.

STREET WORK, New York City.—Proposals are wanted until July 1, for the improvement of certain streets. Address the Department of Public Works, as above.

GULLY WELLS, Quebec.—Proposals are wanted until June 11, for the construction of certain gully wells. Address W. D. Baillairge, Assistant City Engineer, as above.

STREET WORK, Cleveland, O.—Proposals are wanted until June 11, for the improvement of certain streets. Address C. G. Force, City Civil Engineer, as above.

PUMPING PLANT, Ottawa, Ont.— Proposals are wanted until June 27, for furnishing the pumping plant at the Kingston Dry Dock. Address A. Gobeil, Secretary Department of Public Works, as above.

WATER MAINS, ETC., Carthage, Ill.—Proposals are wanted, no date specified, for 4,000 feet additional water mains and ten fire hydrants. Address S. W. Merrill, City Clerk, as above.

SEWERS, St. Paul, Minn.—Proposals are wanted until June 12, for constructing sewers in certain streets at this place. Address J. T. Kerker, Clerk Board of Public Works, as above.

DREDGING, Brooklyn, N. Y.—Proposals are wanted until July 2, for dredging at Navy Yard at this place. Address N. H. Farquhar, Navy Yard, as above.

BRIDGES, Oil City, Pa.—County Commissioners of Venango Co., Pa. (office at Franklin), invite proposals, up to June 19, for four single-span iron bridges, 64, 57, 42 and 36-foot span Also, up to June 18, they invite proposals for stone abutments for each of said four bridges.

Olive st, 2-story br bldg; cost, $12,000; o, D Arnold.

Market st, 3-story br bldg; cost, $8,000; o, J A Niles.

Chestnut st, 3-story br bldg; cost, $7,500; o, F C Davis.

Broadway, 2-story br bldg; cost, $52,500; o, St Louis R R Co.

Bell av, 3-story br bldg; cost, $15,000; o, Paramore Investment Co.

Bell av, 2-story br bldg; cost, $12,000; o, J D Paramore.

Magazine st, 2-story br bldg; cost, $20,000; o, Schuchmann.

STOCKTON, CAL.—A $40,000 hotel and theatre will be erected here. For particulars address S W Newell, as above.

ST. PAUL, MINN.—A power house will be erected by the City Railway Company at Hill and Ontario sts, for the proposed electric line.

Ashland, nr Kent, 3-story br dwell; cost, $18,000; o, John E Williams.

Selby, nr Dale, 3-story br dwell; cost, $17,000; o, same as above.

Selby av, dwell; cost, $18,000; o, John E Williams.

Colorado nr S Robert, 4-story st bldg; cost, $50,000; o, Xavier S Pierre.

6th, cor Wabasha, 5-story br block; cost, $150,000; o, P J Kavanagh.

State nr Concord, 2-story br dwell; cost, 18,000; o, Peter Rohantsen.

YORK, PA.—Mr J A Dempwolf, architect, has been employed by the York Hotel Company to design a 6-story hotel with all the modern improvements; elevators will run to the dining room on sixth floor; drawings are being made; cost, $82,000.

YPSILANTI, MICH.—3-story stone warehouse; cost, $8,000; o, N W Glover; a, M L Smith & Son; b, not let.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D.C.

VOLUME 22. NUMBER 2. PUBLISHED EVERY SATURDAY. 277 PEARL ST., NEW YORK.

NEW YORK, JUNE 14, 1890.
LONDON, JUNE 28, 1890.

SINGLE COPIES, TEN CENTS. Subscription, $4.00 per year in advance, post paid. IN AMERICA.
SINGLE COPIES SIXPENCE. Subscription, 20*s*. per annum in advance, post paid. IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street*, *New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.
TERMS, $4 PER YEAR, IN ADVANCE.
20*s*. in GREAT BRITAIN. Other Foreign Countries $5.
Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & CO., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $5; China, Japan, Sandwich Islands, Mexico and Cuba, $5; South America, $5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

THE PROPOSED WORLD'S FAIR AT CHICAGO.

CHAUNCEY M. DEPEW, who recently returned from a trip to Chicago, gives, in the New York *Tribune*, an encouraging account of the prospects for the World's Fair to be held in that city in 1892. Mr. Depew reports the greatest enthusiasm all through the West over the project, and announces to doubters in other parts of the country that the city has already $5,000,000 in cash and that they will get $5,000,000 more from the Legislature. He very properly urges that the United States Government should give moral support to the enterprise to make it as successful as it should be, since without this Governmental recognition foreign exhibitors are not likely to consider the enterprise a sound one. He thinks the fair will be a great thing for the West, and that it should double Chicago's population within ten years, and that it will be of great advantage to the Western railroads. It, of course, is to be expected that in an undertaking of this sort there will be during its inception and progress more or less local friction. It is to be hoped, however, that critics will profit by Mr. Depew's example, and not hasten to magnify every local criticism to the injury of the project and thus unnecessarily increase the heavy burdens of those who will be responsible for the carrying on of the undertaking, which should have the sympathy and encouragement of all sections.

CROTON AQUEDUCT CONTRACTORS' CLAIMS.

THE bill passed by the New York Legislature giving claims of the Croton Aqueduct contractors now pending precedence over all other cases in the courts of the State has failed to become a law by the refusal of Governor Hill to sign it.

Though less outrageous than the bill which preceded it and was passed by one branch of the Legislature, creating a special tribunal for determining the claims, it was still plainly wrong in principle, and had it become a law would have made a bad precedent, to say nothing of direct mischief possible under it. The first named bill, referred to in the issue of this journal for April 19, was withdrawn, and for its disappearance the community is specially indebted to the New York *Tribune*, which denounced it early and late, and was in a position to be especially influential with the Legislature.

The Aqueduct Commissioners may be depended on to interpose no needless delays to the prosecution of any suits, nor will the city's law officers. We have no doubt the contractors will collect all just and equitable claims, if not by agreement with the Commissioners, then through the medium of the courts of the State.

DRAINAGE OF LOUGH ERNE, IRELAND.

AT a recent meeting of the Institution of Civil Engineers a paper was read by a member, James Price, Jr., on the drainage of the Lough Erne district in Ireland, of which work he was the resident engineer.

The district comprises over a million acres and the works which have been carried out were designed by James Price, Sr., also a member of the Institute, in 1878. They consisted in cutting a channel through a rocky barrier at Belleek on the River Erne below the Lower Lough Erne, controlling the discharge through this channel by large sluice gates and improving the channel above Belleek and also between the two loughs. The channel at Belleek was excavated under the protection of clay dams.

The sluice gates when closed retain the water at its normal summer level, but when a heavy rain commences in the upper part of the district they are raised so as to permit the 27,643 acres in the lower lough and the 9,453 acres in the upper lough to be drawn down six inches. Thus the flood is provided for before it arrives and the overflow of adjacent land is prevented. Allowance was made for a discharge of 600,000 cubic feet per minute, but by opening in advance a discharge of 500,000 cubic feet per minute proved sufficient.

These sluice gates, four in number, were designed by F. G. M. Stoney, M. Inst. C. E. They are 29 feet 2 inches wide, 14 feet 6 inches high with a lift of 9 feet. Each gate weighs 13 tons, but as it bears on a train of 8-inch live rollers one man can easily raise it the full height in 45 minutes, and a turbine can lift the four gates simultaneously in half an hour.

The total cost of the gates, exclusive of masonry, was £4,000. The total cost of the entire works was £180,000, of which £30,000 was for navigation and £150,000 for drainage. Large compensation had to be paid for anticipated injury to fishery rights, although the works have actually improved the salmon fishery.

Observations of the rainfalls, lough levels and sluice discharges for four years showed that the storage in the loughs affected but little the summer flow and indicated that the great reservoir for the summer flow of a river was the ground water. The general effect of the drainage works had been to keep the level of the loughs more uniform, higher in summer and lower in winter, and by preventing the flooding during a wet summer of fifty square miles of adjacent low land not only was the loss of that year's crop of hay avoided, but also injury to the following crop, which was apt to be damaged by the decayed grass of the previous season. These extensive tracts of damp land also so chilled the air as to interfere with the ripening of neighboring crops, to say nothing of their injurious effect on the health of the community.

The author advocated the following general principles in designing drainage works: First, that the cross-section of the enlarged channels should be hyperbolic instead of trapezoidal, thus increasing the discharge in proportion to the section, obviating slips by flattened slopes next the land, facilitating dredging and confining the low-water channel so that the sides could be cleaned. Second, that the channels should be given a fall of only one or two feet per mile, with embankments and back drains where necessary and accumulating any excess of fall at certain points where the discharge might be effected along paved channels. While embankments were generally avoided in Ireland, it was, in the opinion of the author, clearly a mistake to lower a large river to avoid flooding a small area, and, though not applicable to the Erne, embankments should be used for the Barrow drainage. The extension of arterial drainage in Ireland would, he thought, render large areas of ground available and would raise the mean summer temperature, which at present is only 58° Fahr.

The initiation of such schemes can, however, no longer be left to the landowners, who, under their altered conditions of tenure, have lost their former interest in the improvement of their estates.

A SUBWAY FIRE IN NEW YORK.

A FIRE started from a leak in a gas main on Broadway at the intersection of Fulton Street, New York City, Thursday morning, and burned all day. The New York Steam Company had a trench in the street at this point to its pipes, which run under the gas mains, and at 2:30 o'clock Thursday morning a workman dropped his lantern in such a way as to ignite gas escaping from one of the latter, a fierce flame finally followed, and it was not until 7 o'clock in the evening that the fire was under control. The wooden curb of the trench caught fire, the heat melted the lead in other gas mains, of which there are a large number crossing at the place, and every leak added fuel to the flame. Attempts were made to put the fire out by filling the trench with earth, but the volume of gas escaping had become so great that this was unavailable. Then the gas companies set to work to shut off the gas by air or water bags introduced in the mains on all sides of the fire. This made about 24 pipes to stop in all, from 8 to 16 inches in diameter, as there are probably 12 mains crossing at the point indicated, it was not known just which ones were making the trouble, and each one must be stopped on both sides of the fire. The rubber air-bags, it should be understood, are introduced when empty in the mains through plug holes, and then filled with air by a force-pump until they expand and stop the pipe. In like manner an oiled cotton cloth bag of larger diameter than the main is introduced to the larger pipes and filled with water, and a static pressure maintained sufficient to stop the passing of gas.

After about ten hours' work with air and water bags the escape of gas was reduced so that the flames were extinguished by throwing wet clay on the leaks. The electric lighting conduits and cables on the east side of Broadway were destroyed by the heat, and it was feared that the telephone cables in the subway on the west side of the street would be ruined, but, so far as can be ascertained, they were not injured.

RAPID TRANSIT SCHEMES IN BOSTON.

A BILL has just become a law in Massachusetts directing that any railroad or street railway company in the State may build the Meigs system of elevated road, provided that cities and towns in which the lines run assent. The assenting in the case of cities is to be by a majority of all the members of the Council, and in towns by a majority of the voters present at a special town meeting, besides which the location in Boston shall be first approved by the Board of Railroad Commissioners. The Meigs Company has sent a petition to the Board of Aldermen which contemplates laying out an elevated railroad system in this city extending to Charlestown, Brighton, Roxbury and South Boston, with branches to Cambridge and Somerville, and several other rapid transit schemes are being pressed in the city.

THE COLUMBIA COLLEGE SCHOOL OF MINES.

AT the Columbia College Commencement this week degrees were conferred in the School of Mines as follows:

Engineer of Mines.—Alexander L. Black, Edwin M. Blake, William M. Davis, Albert L. Levy, Manuel R. Montenegro, Howard F. Welsh.

Civil Engineer.—George A. Beckwith, Romeo T. Betts, Dwight D. Book, Joseph Carson, Diego L. Clark, Hewlett R. Connell, Thomas C. Coykendall, Andrew E. Foyé, Charles E. Gudewill Charles H. Hart, John S. Hoyt, Elisha D. Hurlbut, Jr., Louis F. Massa, Thomas M. R. Meikleham, José Portuondo, Albert C. Fowler, Alger C. Gildersleeve.

Metallurgical Engineer.—Frederick I. Cairns, George J. Hicks Frank C. Hooper, Thomas J. Jones, William H. McKleroy, Thomas M. St. John.

Bachelor of Philosophy.—(Course of Analytical and Applied Chemistry.) Joseph A. Deghuée, George A. Ferguson, Bertrand C. Hinman, Herschel C. Parker, James R. Steers.

Bachelor of Philosophy.—(Course of Architecture.) Samuel W. Andrews, Jr., Herman Behlen, Will A. Buckland, William R. Clayton, Frederick G. Colton, Lloyd W. Fisher, James Monroe Hewlett, Meyer Jarmulowsky, Robert D. Kohn, Edward G. Lichtenstein, William S. Lowndes, Horace B. Mann, William Stone Post, William L. Thorne, Charles Peck Warren, Alexander M. Welch.

A MOVEMENT is started in Wilmington, Del., to establish free public baths.

ANNUAL CONVENTION OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS.

PAPERS to be read at the convention of the American Society of Civil Engineers, which opens at Altoona, Pa., June 26, are announced as follows:

"On a Method of Taking Cross-Sections of Deep Rock Cuts by Triangulation," F. W. Watkins.

"On the Littoral Movements of Inlets along the Coast of New Jersey," Lewis M. Haupt.

"The Designing and Erection of the Oakley Arch," J. Foster Crowwell.

"The Stability of Loaded Masonry Arches," A. S. C. Wurtele.

"Irrigation in India," Herbert M. Wilson.

"Construction and Maintenance of Track," Julien A. Hall.

"Street Electric Railways," O. H. Landreth.

"The Ventilation of Tunnels," N. W. Eayrs

"Inland Sewage Disposal with Special Reference to the East Orange, N. J., Works," Carrol Ph. Bassett.

"The Three River Spans of the Bridge Recently Completed Across the Ohio River at Cincinnati," William H. Burr.

"The Beginnings of Engineering with Special Reference to Early Engineering Science in America," J. Elfreth Watkins.

"On Truss Bridges," Onward Bates.

"One Way of Obtaining Brine," Charles B. Brush.

"The Self-Registry of Effects of Strain in Metals," Robert H. Thurston.

"Comparison of Water Supply Systems from a Financial Point of View," J. Leland FitzGerald.

RADIATOR MANUFACTURERS' MEETING.

THE Association of Steam Radiator Manufacturers held a meeting at Buffalo this week, with about 15 delegates present representing many of the large works. A press report says that the old prices were re-adopted, and that an effort to reduce the cash discount from 2 to 1 per cent. failed.

Among the concerns represented were the A. A. Griffing Iron Company, Jersey City; Detroit Radiator Company, Michigan Radiator and Iron Manufacturing Company, Detroit; the Crane Company, Chicago; T. H. Brooks & Co., Cleveland; Nason Manufacturing Company, New York; The H. B. Smith Company, Westfield, Mass.; Gurney Heater Company, Boston; T. C, Joy, Titusville, Pa.; and Pierce Steam Heating Company, Buffalo.

FACTS ABOUT BRIDGES WANTED.

O. CHANUTE, F. C. Carter, J. F. Wallace, M. Seifert and W. E. Williams, a committee appointed by the Western Society of Civil Engineers to report as to the regulation of the construction and maintenance of bridges, have issued a circular asking for information upon the following points·

Foreign custom and laws in regard to the construction and inspection of railway and highway bridges.

The manner in which this question has been treated and any legislation had thereon in the United States.

The points in bridge designing and construction which need special attention.

Former bridge accidents and their causes.

Standard plans and designs of railway bridge floor systems.

Information should be sent to the Committee on Bridge Legislation, Western Society Civil Engineers, 78 La Salle Street, Chicago, Ill.

WORK ON THE NICARAGUA CANAL.

SOME details of the beginning of work on the Nicaragua Canal are given in a dispatch to the New York *Times*. Work on the canal itself has been confined to clearing a track over the course proposed for it through the forest from Greytown 16 miles to the top of a rocky ridge. This clearing is 1,000 feet wide at Greytown, but soon narrows to 500 feet. It is here that some very expensive work on the waterway will come. Near this clearing, and nearly parallel with it, another narrower way has been cut for a railroad to the Silico Lagoon. A contract for 12 miles of this line has been let to C. P. Treat, and ground was broken upon the work May 20.

The jetty to improve the harbor has been extended about 500 feet, and the outer end is now in 11 feet of water. Work had been suspended for some time from want of material, but had recently started again. The jetty is 43 feet wide, with four rows of piles eight feet apart, inclosed with sheet piling, and the space filled. The piles are sunk 15 to 18 feet in from 3 to 5 minutes with a water jet, and then driven to 20 feet. For filling mattresses of brush are put down and secured in place by broken rock, when the sand drifts in very fast, and has even piled up by the side of the jetty so that the shore line seems to follow the work. Rock is so scarce that the same pieces have been used for fixing the mattresses over and over again, but when the railroad reaches the "divide" an abundant supply will be available, with which it is proposed to supplement and strengthen the structure. Frank P. Davis, divisional engineer, is now in charge of the work, assisted by civil engineers Hunt, Holcomb and others.

THE CHESAPEAKE AND OHIO CANAL.

THE receivers appointed by a Maryland court to take charge of the Chesapeake and Ohio Canal have reported against repairing it for use as a waterway, on the ground that it could not be operated profitably in the face of railroad competition. The total cost of necessary repairs is put at $268,698. The report says that by ordinary competition in rates it would not be possible to operate the canal, and that therefore the receivers applied to the owners of Allegheny coal mines to give guarantees of enough shipments to warrant opening the canal and so maintain a check upon the railroads. All that could be got, however, was a promise of shipping 450,000 tons of coal annually for four years and, basing their calculations upon this, the receivers made an estimate of the total income of the canal of $189,963 per year for the period indicated as an outside figure, while the running expenses are put at $135,106 and the interest on certain bonds would increase the outgo to $193,700. After the four years expired the report intimates that the canal could not possibly be operated, and the substantial conclusion is that all thought of it as a waterway must be abandoned.

THE CHICAGO DRAINAGE LAW UPHELD.

A PRESS dispatch says that the Illinois Supreme Court has affirmed the validity of the act known as the Chicago Drainage Law, which has for its general purpose the taking of the city sewage and the water of Chicago River along the line of the Illinois and Michigan Canal and thence to the Illinois and Mississippi Rivers by gravity.

SENATOR EVARTS, of New York, has introduced in the United States Senate a bill authorizing the construction of a bridge over the Hudson River, under what is known as the "Greene" charter, located anywhere between Tenth Street and One Hundred and Eighty-first Street, New York City. The incorporators have organized and voted to open stock subscription books, but the time for doing this was not fixed.

AT the Commencement of the University of the City of New York this week, the degree of Civil Engineer was given G. W. Bond, G. T. McNab, A. D. Phillips and A. B. Samuelson.

OBITUARY.

W. H. HARRISON, Superintendent of Bridges of the Chicago, Santa Fe and California Railroad, died suddenly at Scranton, Ill., June 5.

WILLIAM BUCHANAN, of Cedar Rapids, Iowa, Treasurer of the Cedar Rapids Water Company, died Tuesday, at the age of 59 years.

JOHN W. TAYLOR, of Somerville, N. J., who supervised the construction of the Raritan Water-Works in 1839 and had since been in railroad and banking business, died June 7, at the age of 68 years.

PERSONAL.

L. H. CRAMER has just been re-elected Village Engineer of Saratoga, N. Y. This was Mr. Cramer's eighteenth successive election to the place.

FRANK L. SUTTER, architect, Dayton, O., has moved from the Barney Block to room 15 in the new Jefferson Block.

WILLIAM S. BACOT, of New York City, has been given the honorary degree of Civil Engineer by Princeton College. Mr. Bacot graduated at Princeton in 1881.

E. P. RIPLEY, General Manager of the Chicago, Burlington and Quincy Railroad, has sailed for Europe, to be absent a short time. Upon his return he will assume the duties of Vice-President of the Chicago, Milwaukee and St. Paul Road.

S. H. HARRINGTON, has resigned his position as Mechanical Engineer of the Erie Railroad at Susquehanna, Pa., and accepted a position with the Gould Manufacturing Company, of Buffalo, N. Y.

J. D. MOLER, until recently City Engineer of Springfield, O., has taken his son, William G. Moler, C. E., formerly Superintendent of Schools at Greenfield, O., into partnership, and the firm will do a general engineering and contracting business, with headquarters at Springfield.

COMING MEETINGS.

THE annual convention of the American Society of Civil Engineers will open at Cresson, Pa., at 10 o'clock Thursday morning, June 26.

ENGINEERING SOCIETIES.

THE CLEVELAND CIVIL ENGINEERS CLUB held a meeting Tuesday evening, with W. H. Searles in the chair. Albert H. Porter was elected Secretary. Dr. Herman Poole read a paper on "Ferroid," which he described as a new composition stone made of sulphur, iron and silicon, about one-third as heavy as iron, and of a deep slate color.

THE ENGINEERS' CLUB OF ST. LOUIS held a meeting June 4, with President Nipher in the chair, W. H. Bryan, Secretary, and 30 members and 3 visitors present. J. G. Jennings was elected a member.

Mr. Russell, Chairman of the Committee on Local Data, presented his report. The nature of the matter collected was explained, and it was ordered that the committee be continued, with authority to employ expert assistance, if necessary, to edit the report, and to get for the club estimates on the cost of publication.

The report, which is intended to be printed as a handbook for the club, gives the cost of different kinds of masonry and foundations, cost of railway construction and railway location, steam heating, street reconstruction, the amount of rainfall, etc.

Professor Nipher called attention to the fact that rainfall in the State of Missouri was almost exactly equivalent to the river discharge at St. Louis.

A DIRECT ACTING HYDRAULIC PUMPING ENGINE.

KNIGHT & Co., Engineers, of Sutter Creek, Cal., have brought out a type of direct acting pump designed to be driven by water pressure under heads of from 300 to 500 feet or more if desirable.

The main cylinder is 12 inches diameter, and is of wrought iron, and the side pipes are steel castings. The principal feature, and the one that finally led to noiseless and successful working, is the use of independent exhaust valves. The induction valves are moved from an auxiliary cylinder. The working of the machines is said to be quite noiseless and without jar, even when 500 feet of heavy pump rod is connected with the engine. Four of these large pumping engines are now working with driving "heads" as follows: one with 336 feet, two with 460 feet, and one with 720 feet. The efficiency of the engines, it is claimed, reaches 75 per cent.

SLOW-BURNING CHARACTER OF WOOD POSTS.

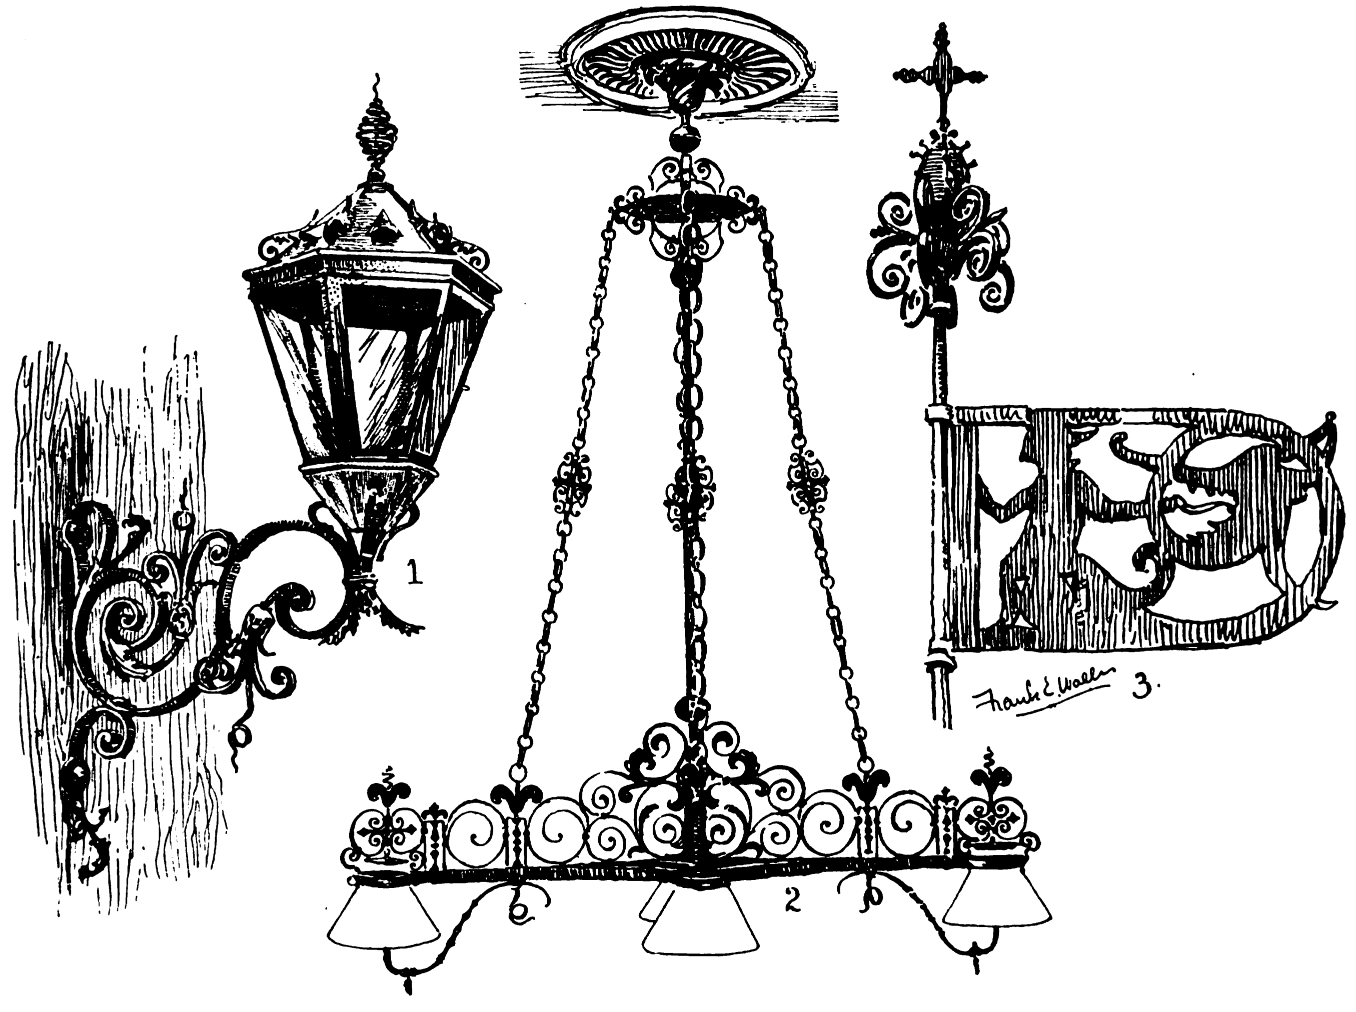
THE endurance of wooden posts when subjected to fire is commented upon by the London *Architect* in referring to a fire which occurred in a large warehouse and raged with great fury for five hours, at the end of which time it was extinguished.

The warehouse was built with brick walls. It had wooden floors supported on wooden beams, which, in their turn, were carried on wooden story posts about 12 inches thick, and, although serious damage was done, not one portion of the heavy woodwork was destroyed. After the fire the proprietors allowed the chief of the fire brigade to remove one of the story posts, with a section of the beams and other parts surrounding it above and below. This post had been subjected to the full action of the fire during the whole of its duration, or, making full allowance for everything, including the delay of the fire attacking the particular spot on which it stood and the time at which the cooling process commenced, certainly not less than four and a half hours. As large quantities of water had been used and it was probable that everything had been saturated, the wood was carefully dried before a strong fire until not a trace of moisture remained in it. It was then set on end in an open yard, exactly as it had stood in the warehouse, with the pedestal underneath, the cap above, and the beam across the cap. More than a ton of shavings, light wood and heavy wood were placed around it, and, after the whole heap was saturated with petroleum, a light was applied to it, and after this large quantities of petroleum and turpentine were pumped on it. At the end of two and one half hours the post, beam and other parts were withdrawn from the fire, and within a few minutes of the time they were withdrawn they ceased to burn. A few feet were then sawed off horizontally, at that part which had suffered most from the flames, and afterward the same place was split longitudinally with steel wedges, in order to examine its condition. The post was of pitch pine—about the most inflammable wood known—and yet, after exposure for seven hours to fire, the fury of which could not be exceeded except in blast furnaces, it contained a quantity of perfectly uninjured and apparently fresh wood, probably capable of supporting the whole weight which the post was designed to carry. Immediately after the saw cut, and again after the cleaving with steel wedges, the center was carefully examined, and found to be just perceptibly warm to the touch, but nothing more, thus proving that the fiber, in which the strength lay, was quite uninjured.

ELECTRIC POWER FOR CRANES.

ONE of the English papers directs attention to the fact that in one of the most extensive timber yards in England an electric moter is attached to the frame of one of the cranes and geared with friction gearing to a central shaft, which, by means of three levers and a foot brake, performs the operations of hoisting and slewing and propelling the crane. The current is conveyed to the electric motor by two copper tubes laid along the tramway on which the crane runs, and taken off by suitable contacts. In other respects the crane is of the ordinary build. The power is derived from an 18-unit Crompton dynamo, which supplies 300 incandescent lamps employed in lighting a factory. It gives a current having an electromotive force of 110 volts, and some 30 amperes are used for working the crane. It was specified that the crane should lift 15 cwt. as a maximum load, and raise 10 cwt. at a speed of 80 feet per second, and slew at the same speed. It, however, lifts 18 cwt., and in other respects, also, is said to improve upon the specifications.

In connection with this it is of interest to note that at the Alliance, O., shops of the Morgan Engineering Company a traveling crane is driven by a single electric motor, which has all the usual movements.



WROUGHT IRON WORK.—FIGS. 1 AND 2 BY JOHN WILLIAMS, NEW YORK CITY. FIG. 3 IN SOUTH KENSINGTON MUSEUM.

NEW ENGLAND WATER-WORKS ASSOCIATION CONVENTION.

(From our Staff Correspondent.)

PORTLAND, ME., June 12.

FIRST DAY'S SESSION.

THE ninth annual convention New England Water-Works Association opened here yesterday. Headquarters were provided at the Falmouth Hotel, and the meetings were held in the City Hall.

The convention was called to order at 2.45 o'clock, with President Dexter Brackett in the chair and R. C. P. Coggeshall Secretary, and 102 members and visitors present. In his opening address President Brackett made a brief statement of the work of the association, its aims and purposes, and referred to its growth as shown by its increase in membership from 43 at the second convention to 335 now. Two-thirds of its active members are residents of New England, but it has representatives from 25 States and territories outside of New England.

He dwelt upon the advantages of encouraging excursions and social meetings as favoring an interchange of ideas between members as to the practical discharge of their duties in the management of water-works. Brief reference was made to the various papers presented to the members at their several meetings during the winter, especially the papers by John R. Freeman on "Fire Streams"; that of F. F. Forbes, of Brookline, Mass., on "Algæ in Reservoirs and Ponds," and to the various short experience papers on matters pertaining to the management of water-works, given at the meetings in February and March. He suggested a few subjects which he thought should be brought up for future discussion, as follows: "How to Preserve and Improve the Quality of Water," "Cast or Wrought-Iron Pipe, its Thickness, etc.," and "Waste of Water." The careful consideration of these and kindred subjects is one of the chief objects of the association. In closing his remarks Mr. Brackett referred to the valuable work rendered to the association by the Secretary, Mr. Coggeshall, and thanked the society for the courtesy and attention extended to him as President during the past year.

The Secretary's report was next presented and accepted. It shows an increase in membership from 277 in June, 1889, to 335 at this time, consisting of 257 active, 4 honorary, and 73 associate members. The report of the Treasurer, Hiram Nevon, of Cambridge, Mass., and that of the Finance Committee were presented and accepted. They showed total receipts, $3,475.95; expenditures, $2,346.65; balance on hand, $1,129.30. It was voted that a committee of five be appointed to nominate officers for the ensuing year. The President announced that he had a telegram from Mayor Clark, of Toronto, inviting the association to hold their next annual convention at that place, and it was voted that a committee of five be appointed to consider this invitation and the general question of the place of the next annual convention.

On behalf of the Committee of Registrars appointed at a previous meeting to report upon "Classification of Water Rates," J. C. Whitney, Registrar of Newton, announced that from the 450 answers to circulars sent out by the committee they had received no data which would enable them to come to any definite conclusion on account of the almost total want of uniformity in these rates as tabulated. The committee, however, indorsed the report of the committee of 1887, and requested an extension of time to further investigation. It was voted that this committee be continued and report at a future meeting.

A paper by Charles W. Morse, Superintendent of the Water-Works at Haverhill, Mass., was presented, in which the writer maintained that water-works built and conducted by a private company yield greater benefit to the people than is possible under municipal control, and he endeavored to show how greater economy and efficiency can be attained under the former than under the latter management. In the discussion that followed several members participated.

F. L. Fuller, of Boston, referred to his experience with the water-works of four towns, where in each case the commissioners appointed were entirely competent, reliable men, selected with special reference to carrying on their special work, and in each case the work as done was better than would have been possible under a private company. Many water-works are constructed by towns which would not be attempted by a private company.

Mr. Hawes, of Fall River, thought that municipalities should own and operate water-works, and all works which concern the public good. This can be done much cheaper under municipal than under private control. The best works and the lowest rates are obtained from municipal management, and not from private corporations.

E. W. Cato, of Newton, Mass., said that he considered the question both from a theoretical and practical point of view. To start with, it should be assumed that both the city and the private company have honest and competent officials. All works for public use should be constructed and operated by public officials. Municipalities have greater resources and more extended legal rights than private corporations, and, therefore, can more economically and efficiently construct and operate public works. Theoretically, municipal management is the best. Practically, the merits of each individual case should be determined independently.

Mr. Holden, of Nashua, N. H., spoke of a number of towns as "progressing backwards" on account of their unwillingness to build water-works, which encouraged manufacturing. In a number of cases the development of the manufacturing industries of towns was due entirely to the building of water-works by private companies when the town itself would never have done the work.

The paper was also discussed by F. W. Whitlock, of Waterbury, Conn., and Solon M. Allis, of Malden, Mass.

NEW MEMBERS.

The following new members were elected:

Resident Active Members.—James Burnie, Superintendent of Water-Works, Biddeford, Me.; Francis W. Dean, Hydraulic Engineer, Boston, Mass.; Charles R. Dyer, Superintendent of Meter Department, Portland, Me.; Eben R. Dyer, Superintendent of Construction, Portland, Me.; W. J. Goldthwaite, Water Commissioner, Marblehead, Mass.; F. W. Gow, Assistant Superintendent, Medford, Mass.; Arthur W. Hunking, Hydraulic Engineer, Lowell, Mass.; James T. Murphy, Water Commissioner, Marlboro, Mass.; William McNally, Water Registrar, Marlboro, Mass.; William Jackson, City Engineer, Boston; A. F. Crockett, President Camden and Rockland Water Company, Rockland, Me.

Non-resident Active Members.—William Hamilton, Superintendent, Toronto, Ont.; Charles W. Pratt, Superintendent, Utica, N. Y.; J. Nelson Tubbs, Chief Engineer of Water-Works, Rochester, N. Y.; E. M. Treman, Superintendent, Ithaca, N. Y.

Associate Members.—James C. Bayles, Hydraulic Engineer, East Orange, N. J.; King & Goddard, Pipe Fittings, etc., Boston; Perrin Seamans & Co., Water-Works Supplies, Boston; Rensselaer Manufacturing Company, Water Valves, etc., Troy, N. Y.; Standard Thermometer Company, Instruments, Peabody, Mass.; Taunton Locomotive Manufacturing Company, Machine Works, Taunton, Mass.; J. N. Winslow, President Stoneware Company, Portland, Me.; E. B. Winslow, General Manager, Stoneware Company, Portland, Me.

[This report will be continued next week.]

MAYOR ALGER, of Taunton, Mass., has sent a special communication to the Common Council urging at length the immediate construction of a system of sewers. He gives many details showing the inadequacy of the present sewers and the pressing need for replacing them with something better, and favors carrying out a comprehensive sewerage scheme submitted some time ago by Phineas Ball, C. E., of Worcester, Mass.

ARTESIAN WELLS IN NEW ENGLAND.

A TABLE showing the artesian wells in New England is given in the report of the Water Commissioners of Taunton, Mass., for 1889. This table shows that of 34 New England wells ten yield 70,000 gallons or more, and seven yield more than that at Taunton; three yield 200,000 gallons or more, but none yield as much as 500,000 gallons. All the wells in New England more than 1,000 feet deep have been failures.

Four are flowing wells, but two of these require pumping to be of any use. Sometimes wells are exploded in the hope of opening a water vein near the bore, but not more than one in three of these shots is successful, and sometimes matters are made worse.

Samples of the material were taken from every 6 or 7 feet of depth, from which George F. Chace, the Superintendent of the Taunton Water-Works, has made a large chart showing the geological formation passed through and the dip of the strata, which was about 40 degrees. The table is as follows:

LOCALITY.	Diameter in inches.	Depth in feet.	Gallons in 24 hours.	Rock strata.	Depth at which rock was first reached.	Does well flow?	Quality of Water	Result of exploding.	Remarks.
York Beach, Me....	6	51	120,000	* Hard sandstone.	2	Yes.	Good.	No shot.	* Sometimes called "blue granite."
Bennington, Vt........	....	1000 1000	....	.. ..	100 20	... .	....	"	Failures.
34 Providence St., Boston.	7⅝	2503	Inexhaustible.	Granite and slate.	159	5 ft. of surface.	Too much sulphuret of hydrogen	"	Good water: 459 to 484; well spoiled by going too deep.
Boston Gaslight Co.	....	1750	....	Slate. and Conglomerate.	80	No.	Much mineral and vegetable matter.		
Dorcester	....	870 900							
Dighton, Mass...	6	50	200,000	....	15	5 ft. of top.	Salt.	"	J. C. Jessup & Co.
Hopkinton, Mass... ...	6 6 6 8	58 65 75 119	50,000 58,000	Broken granite.	18 14 8 2½	No. " " "	Fine. " " "	" " " "	
Clark's Cove Guano Co. New Bedford, Mass ..	6	510	5,000	Granite and limestone.	12	"	Too near salt water.	Good results.	
North Adams, Mass...... Belden Silk Mill.....	8 8	500	900,000	Limestone.	80	4 ft. of surface.	Good, but very hard.	No shot.	
Northampton, Mass......	8	3700	7 gals. per min.	Conglomerate sandstone.	150	No.	Not good.	"	700 lbs. dynamite; total failure.
Lowell Hosiery Co., Lowell, Mass..... ...	6-4	303	24,000	Trap or mortar stone.	15	"	Poor.	"	Twice gained 25 per cent.
Malden, Mass	8	650	93,600	Quartz.	70	"	Fair.		
Stockbridge, Mass.	8 8	300 650	40,000 to 60,000	Limestone and mica schist.	50	"	"	"	This well an utter failure.
Fall River, Mass....	6	180	43,200	Granite.	13	No.	Fair.	No shot.	
Taunton, Mass., Lunatic Hospital	6	89	90,000	* Blue granite.	27	"	Good.	"	* Called by geologists sandstone.
Taunton, Mass., Morton Laundry...	6	96	20,000	Slate and sandstone.	26	1 or 2 gals per min.	"	"	
Taunton Water-Works ...	8	975	75,000	Slate and sandstone.	85	12 ft. of surface.	"	"	
West Cummington, Mass.	8	625	3,600	....	10	No.	Too much iron.	"	
Darien, Conn.	6	215	16,800	Granite.	42				
Fitch's Soldiers' Home.	8 8	251 80	8,000 to 12,000 12,000 to 20,000	Conglomerate schist.	20 20	Flows few gals. per hour.	....	.. ....	Shooting did no good.
Meriden, Conn. ...	8 8 8	208 205 256	Using 57,600	Red sandstone.	15	Yes.	Hard, clear.	Good results.	
Britannia Works, Meriden, Conn....	12	530	100,000	Brown sandstone.	90	No.	"Hard as lightning."	No shot.	
Stamford, Conn..........	8	450	... ...	....	..	"	Brackish.	"	
Electric Light Co., Newport, R. I........	8	110	75,000	Dark slate.	11	"	Very hard.	"	

OBSERVATIONS AS TO CURRENTS IN LAKE ERIE.

Walter P. Rice, the City Civil Engineer of Cleveland, O., has been conducting some interesting experiments to determine the action of wind and currents on the sewage discharged at Cleveland, in Lake Erie, with a view of locating the outfall to prevent possible contamination of the lake at the water-works intake. His preliminary report is as follows:

Currents and Location of Outfall.—A knowledge of the currents in the lake is necessary in determining the proper location for the outfall. For this purpose, careful observations were made, spar buoys were established at one, two, three, five and ten thousand feet distances from the shore in prolongation of Muirson and Marquette Streets. As a general rule, two floats were released at each buoy, one for surface, and the other mid-depth currents. The movements and positions of floats were noted from time to time, by means of triangulations from a shore base line. The observations on each float from ends of line were practically rendered simultaneous, by means of telegraphic communication. A few observations were also taken at the mouth of the river in the vicinity of the breakwater.

The surface float consisted of a cedar post, carrying a small flag, and weighted with stone at the submerged end. The mid-depth float finally adopted consisted of a combination of a pole float, with submerged oil barrel, having the heads knocked out and sunk by means of weights attached to a couple of cross rods. One float, having more surface exposed to the wind than the other, experiments were made to ascertain what the amount of error would be due to this cause, under similar conditions. Very little difference was noted in the results, however. It is safe to assume that there is some error due to this cause, the effect of which would be to give current velocities somewhat in excess of the true ones.

Bottle Floats.—In addition to the regular observations, bottle floats, with inclosed postal cards, were released at the different spar buoys, ranging from 1,000 to 10,000 feet lakeward. About 21 were heard from. Of a lot released on November 4, six were heard from, as having been found November 18, in the neighborhood of Presque Isle, within a radius of 2 miles. The distance is about 90 miles. A lot released November 1, were found scattered along the coast from Chagrin River, to a point east of Ashtabula, distance 22 to 60 miles from Cleveland; the 60-mile float having been found November 18. A lot released October 28, were found scattered from Willson Avenue to Fairport, the latter being found November 11, distance 28 miles.

Current Observations.—In taking observations it was soon discovered that the currents were controlled by the winds. All current velocities are, therefore, given in terms of the wind velocity—*i. e.*, as a percentage of the latter. The following are the results:

Surface currents from 1,000 feet station to the 10,000 feet station, run from 7 to 5 per cent. up stream, $3\frac{1}{3}$ to $3\frac{1}{10}$ down stream.

The 5,000 feet station shows an excess of per cent. both up and down; $5\frac{7}{10}$ per cent. up, $4\frac{1}{10}$ down.

Mid-depth currents run from $2\frac{56}{100}$ per cent. to $5\frac{8}{10}$ per cent. up, $2\frac{33}{100}$ per cent. to 2 per cent. down.

Five thousand feet no exception

Off piers—Ran $\frac{18}{10}$ per cent. up, $2\frac{4}{10}$ per cent. down.

Surface—Average per cent. up stream 6.03 per cent.; down, 3.54 per cent.

Mid-depth—Average per cent. up stream, 3.893 per cent.; down, 2.071 per cent.

Relation between up and down stream velocities is practically the same in both surface and mid-depth observations, the effect up stream being about double that of down stream. The mid-depth currents increase in power as you go seaward and the under currents are of course less than the surface. While the unfortunate fact is developed that the up stream currents are of greater strength than the down steam currents, it will be shown further on that the prevailing winds are from the west to southeast, thus diminishing the frequency of dangerous currents.

The heaping of the water on lee shores of the lake, due to long continued winds, prove that the water has a movement of translation due to wind. The disturbance of level can only be accomplished by currents, as likewise its readjustment and the head of water produced is a direct measure of the current intensities; the return or readjusting currents taking the path of least resistance in the effort to establish an equilibrium. In deep water the return currents might be along the bottom.

The topography of the south shore of Lake Erie shows a straight coast line, broken by one indentation or pocket, the most southerly point of which marks the location of the city of Cleveland. The general coast line prolonged would pass seven miles out to sea. The city is so situated as to have two-thirds of the lake to the east, and one-third to the west, thus affording double the length of sea for winds blowing from the easterly half of the compass. To my mind this fact principally accounts for the increased strength of currents up the lake, without having recourse to eddy effects which would perhaps exist under favorable conditions.

The different horizontal strata of water from surface to bottom respond to a continued wind in the order of their distance from the surface, so while there may be difference of direction in the upper and lower currents at any given moment, it only depends upon the duration of the wind to have all the currents wheel into line with the wind.

On the assumption that the float velocities are identical with the current velocities, a wind movement (velocity by time) of 80 miles would carry surface currents from Wilson Avenue to the water-works crib, and the mid-depth currents would require a movement of about 123 miles to traverse the same distance. The directions of the wind necessary to produce this movement are N. and N. E., and the frequency of its occurrence in the different months for both surface and mid-depth currents as deduced from the average for three years is as follows:

	S.	M-D.		S.	M-D.
January	4	2	July	13	5
February	3	2	August	9	4
March	6	4	September	5	2
April	8	4	October	3	2
May	8	4	November	3	2
June	7	4	December	2	1

Seventy-three times surface, 36 times mid-depth.

The cross-sections of Lake Erie, at Cleveland, is about 19,985,000 square feet. Taking the mean discharge of the Niagara, at 265,000 cubic feet per second, on the assumption that the lake can be treated as a river, the mean velocity of flow of the section would be about eight-tenths of a foot per minute, and as the average of the mid depth velocities during the present period of observations was 19 feet per minute, it clearly demonstrates that the currents due to flow are modified in direction day by day by the stronger currents due to the winds. In other words, there is no fixed line of current due to natural flow and the lake cannot be considered as a river, but rather as a basin with erratic currents, under control of the winds, and overflowing at the lowest point of the rim.

Corroborative Testimony.—Captains of fish tugs at this port unite in the declaration, that during a northeast wind there is a decided current of water from surface to bottom, up stream, or to the westward, the indications of which are the sagging of gill nets up stream and clogging of down stream side of nets with garbage, leaves, etc. These nets are set at various distances from the water-works crib outward as far as 20 miles; they are 6 feet deep and rest on the bottom. During the last winter, nets set between the crib and Axworthy Point, and for several weeks under the ice, were filled with a thick yellowish fungus growth and were also clogged on the lower side with some of the refuse, apparently dumped from scows. Fish entrails have been taken from the lower side of nets three miles out.

Strongly marked east and west currents have been observed on Lake Huron, due to winds. It is a known fact, and recorded in the pamphlet issued by the Lighthouse Board that changes in wind produce large variations in the discharge through the St. Clair and Niagara Rivers. In my opinion the strongest currents would be produced by the following conditions: A gale or blow of long duration lengthwise of the lake followed by a sudden cessation of wind In other words, the head of water produced at either end of the lake is a direct measure of the currents, and the time occupied in creating the head being greater than the time occupied by its dispersion, the return currents would be of maximum strength.

Movement of the Winds.—In attempting to draw proper conclusions as to the location of the outfall for a sewerage system, the observations on currents proving beyond all question that they are to all practical purposes dependent upon the winds, it becomes necessary to investigate the wind movements. I submit a graphical representation of the wind movements (time by velocity) compiled from the records of the Signal Service from 1883 to 1887 inclusive. January, February and March were omitted, as the lake is generally covered with ice during these months. The experiments of Mr. Whitelaw, however, show the existence of shore currents, even under these conditions, although probably not of great strength. On the diagrams the wind movement is plotted to scale working from circumference to center, so that the shaded portion represents the quantity of wind from all points of the compass. An inspection of the diagram reveals the following:

A great preponderance of wind movement from the west and southeast occurs during the months of October, November and December. The least movement is from the east in every month but August, which is the most evenly balanced month of all as regards the winds. The diagram showing the mean movements for five years during the nine months from March to January shows the following:

The minimum wind movement is from the east, the maximum wind movement is from the west to southeast.

The movement from the northwest, north and northeast being equally distributed and between the two, consequently the prevailing winds are favorable to any outlet east of the water-works crib. With a discharge of the sewage into comparatively deep water and near the bottom the sludge and heavier ingredients will soon settle, as the current movement is very slight. The lighter particles of the sewage ascending within reach of the surface, where the currents meet their maximum intensities, constitute their principal element of danger, and we must look for protection to the laws of diffusion and oxidization.

Unfortunately, circumstances did not permit of an investigation as to the law of diffusion, but in the report of Rudolph Hering and Samuel Gray on the "Disposal of the Sewage of the City of Toronto," the following conclusions are arrived at: That from observations of the flood discharges of the rivers entering the lake at Chicago, Cleveland and Milwaukee, in the case of the former (amounting to several thousand cubic feet per second) the dispersion is such as to render them unobservable at a distance of five miles; therefore that the average discharge is less than 100 cubic feet per second, which would represent the sewage from half a million people, would at that distance be even more thoroughly dispersed and in fact entirely lost.

This conclusion is corroborated by the investigation of John Whitelaw, Superintendent and Engineer of the Cleveland Water-Works, recorded in his report of January 31, 1869, where he makes the following statement: "During the months of January and February of last year, experiments were made and observations taken on the ice with a view of ascertaining if possible how far north the water in the lake was impregnated with the petroleum taste which has been such a source of annoyance for three winters past. For this purpose measurements were taken at right angles from the shore line at the inlet, and east and west of the same. Holes were cut in the ice at short intervals and the water tasted, at the same time the line running out from the inlet was measured and soundings were taken for the purpose of making a profile of the bottom."

After repeated observations it was found that the whole body of water, bottom as well as surface, for a distance of 4,300 feet, north from the shore line and parallel thereto, and for a distance of two miles west and one mile east of the river, was tainted with the taste of petroleum during the whole time the ice covered it. "The last trace of impure water was found at a distance of 3,800 feet north from the inlet, and in thirty feet of water." The distance from Willson Avenue to the water-works crib is about $4\frac{6}{10}$ miles, therefore sewage under infrequent conditions of the wind and current should be so thoroughly diffused as to be lost at that distance.

Final Conclusions.—The outlet should be, as far as possible, removed from the water-works crib, within practical limits, sewage under control of the currents may find its way to the crib from Willson Avenue, under proper conditions.

The outlet should be submerged as near the bottom as possible.

Some expedient might be adopted to prevent the sewage under infrequent conditions from being carried up the lake, if found necessary.

The sewage should be screened before entering the lake.

I would suggest that if the outfall was carried out into the lake at Willson Avenue, a distance of about 1,000 feet, in the shape of an embankment, with properly protected slopes or pile crib work, the same to be furnished with two discharge gates, one at the extremity and the other about half way out on the easterly side, that the conditions would be fairly well satisfied, the outer discharge being used in all cases, but the infrequent ones when the winds and currents are in the direction of the water-works crib, when the inner gate could be opened and the embankment would, with the shore line, form a vast reservoir to retain the diluted sewage during the brief time prior to the change of current to other directions, when it would naturally flow out into the lake and disperse. The expedient of using an inner gate can, if necessity ever demands it, be modified by a spur running from the main embankment parallel to the shore, thus preventing trouble along the beach.

CEMENT PAVEMENT IN ENGLAND.

John Parker, City Surveyor of Hereford, England, recently gave a description of some cement pavement being laid in the town named, which is published in the London *Building News*. The bottom bed, 3 inches thick, consists of clean gravel and cement, in the proportion of six to one, on a solid foundation, the surface or top coat being floated in $1\frac{1}{4}$ inches thick, consisting of 1 inch of clean washed sand, Dalbeattie (or Clee Hill), crushed $1\frac{1}{4}$-inch granite, and cement in equal proportions. Mr. Parker's specifications for the cement used are as follows:

"The cement is to be Portland, of the best quality, ground so fine that the residue on a sieve of 5,800 meshes to the square inch shall not exceed 10 per cent. by weight. A striked bushel shall weigh not less than 109 pounds, nor more than 116 pounds, the cement to be run through a hopper with spout 6 inches above top of measure. When tested, should the proportion which will not pass through the sieve be greater than 10 per cent., a quantity of cement proportionate to such excess must be added. When delivered, it is to be put into a dry shed at Corporation yard, and will not be accepted or paid for until it is tested by samples taken from different sacks or casks. About ten per cent. of its weight of water shall be added and briquettes formed into moulds of 1-inch sectional area at the weakest point. The briquettes, having in the mean time been kept in a damp atmosphere, are to be put into water 24 hours after being made, and remain in water until tested. It must not, at any time of the year, set in less than one hour, and must bear, without breaking, a weight of 350 pounds to the square inch 14 days after the briquettes have been made. If it does not, it will be rejected, and must forthwith be removed from the stores by the contractor."

Some wooden water pipe was recently dug up in Belfast, Ireland, says the London *Builder*, which is supposed to have been laid in 1678. The pipes were square, with a round hole, and occasionally a hole for the joining of smaller or service pipes. The wood was much decayed.

THE ELEVATED CABLE ROAD AT LOS ANGELES.

THE Los Angeles Cable Railway Company has recently built an elevated road on San Fernando Street, Los Angeles, Cal., which presents some unusual features in this class of work. The structure is 1,435 feet long and is parallel to and partly over the tracks of the Southern Pacific Railroad. By agreement between the two companies one row of columns of specified dimensions was to carry the two tracks of the cable company. The accompanying illustrations show how this was done by spreading the top and bottom of each column to a width of 12 feet. The base is imbedded in and anchored to a mass of concrete 15 feet long, 6 feet wide, and 7 feet deep, to insure stability. Upon the column is fixed a cross girder 16 feet long, on top of which the 50-foot longitudinals are placed. The rails are placed directly on the top flanges of these girders, with the cable and carrying pulleys between and below.

The structure was opened for traffic November 2, 1889, and has proved to be very firm and free from vibration with trains at 5-minute intervals, running 12 miles an hour. It was designed for a moving load of 1,000 pounds per lineal foot of track, and a wind pressure of 20 pounds per square foot of surface exposed, which is assumed, so far as the column is concerned, to be concentrated at the track level. The total weight of the structure is 518 tons, or 722 pounds per lineal foot. The contractor for the work was A. Gottlieb & Co., and the engineer was Samuel G. Artingstall, both of Chicago.

TESTING AUTOMATIC SPRINKLER HEADS.

IN discussing a paper on "The Determination of Sensitiveness of Automatic Sprinklers," read by A. F. Nagle at the recent Cincinnati meeting of the American Society of Mechanical Engineers, D. S. Jacobus gave particulars of tests of automatic sprinkler heads made by him, under the direction of Prof. Henry Morton, of Stevens Institute, for the New York Board of Fire Underwriters.

The sensitiveness of a sprinkler head, according to Mr. Jacobus, is only one of the elements that must be considered in determining whether it is perfect enough to be adopted. The capacity of the gas burner used by Mr. Jacobus to heat the oven in which the sprinkler head is tested is such that the temperature is raised to 200° Fahr. in about three minutes, and after this time the radiation of the sides of the oven is so great that the heat increases very slowly, rising to 230 degrees in about five minutes from the start. The average sprinkler operates in about five and a half minutes at 235° Fahr., so that by the time the head opens the temperature of the oven is increasing very slowly, and the error due to the difference of the actual temperature of the air and the reading of the thermometer is not a great one. On account of the existence of this small error, it was proposed to preserve the oven at a constant temperature, say 250 degrees, introduce the sprinkler head without sensibly altering this temperature, and note the time that was required to set off the head by means of a stop-watch. It was, however, decided that the test for sensitiveness as now conducted, was accurate enough, and the above refinement was not adopted.

The following tests are gone through at Stevens Institute on each set of sprinkler heads.

1 Tests in the oven to determine sensitiveness and reliability of action.

2. Tests by applying direct flame at intervals, to the head, to determine reliability of action.

3. Tests of distribution and rate of flow of water through the heads.

The most prevalent and dangerous defect usually found in sprinkler heads is the sticking of the valve to its seat after the releasing device has operated. To test the heads thoroughly in this respect the first and second tests, in addition to being made on the new heads, are repeated on heads that have been connected to piping and subjected to the action of water and of brine for about three months. The action of the water and brine for three months has caused the valves of many heads to stick so that they would not open under ordinary pressure.

The oven used for the sensitive tests is 2 feet in height and of 5 cubic feet capacity. At two of its sides pieces of glass are inserted about one foot long by 6 inches wide. A thermometer hangs at such a height that its bulb is about midway between the top and bottom of the oven. An arrangement of swing joints allows the pipe to be drawn outside of the oven, so that the sprinkler head may be readily screwed to its place. Before pushing the pipe back to its position in the oven a water pressure is made to act on the sprinkler, and any air that may be in the pipe is removed by means of a vent. The sprinkler is allowed to stand about two minutes in order to test for leakage, and then is pushed to its position in the oven. The bulb of the thermometer is placed near the solder joint and at the same height as the latter. The thermometer employed has a translucent scale, which is illuminated by a gas flame placed opposite the window at the back of the oven. A system of plates is used at the bottom of the oven to distribute the heat throughout the same. A gas burner is employed for heating.

A tank is mounted above the oven at such a height that 10 feet head of water is obtained. The sprinklers are usually tested under this small head of water. If the valve sticks to its seat after the releasing device has operated a valve leading to the tank is closed and the pressure gradually increased to that in the city mains, in order to determine if this will open the sprinklers. If the sprinkler opens the exact pressure at which it does so is recorded.

The advantage of employing water in the pipes instead of compressed air, and connecting the sprinklers in the same way that is done in practice, arises from the fact that their reliability of action and their sensitiveness can be tested at the same time. Sometimes sprinkler heads will fail on account of a slight leak starting at the valve, which allows a small amount of water to run over the partly melted solder joint of the releasing device, thus chilling it and preventing the complete opening of the head. This action would not occur if compressed air were used in the pipes, or if the sprinkler were connected in such a way that the water that escaped by leakage would not run over the solder joint and chill it. Various other defects are sometimes found in the releasing devices.

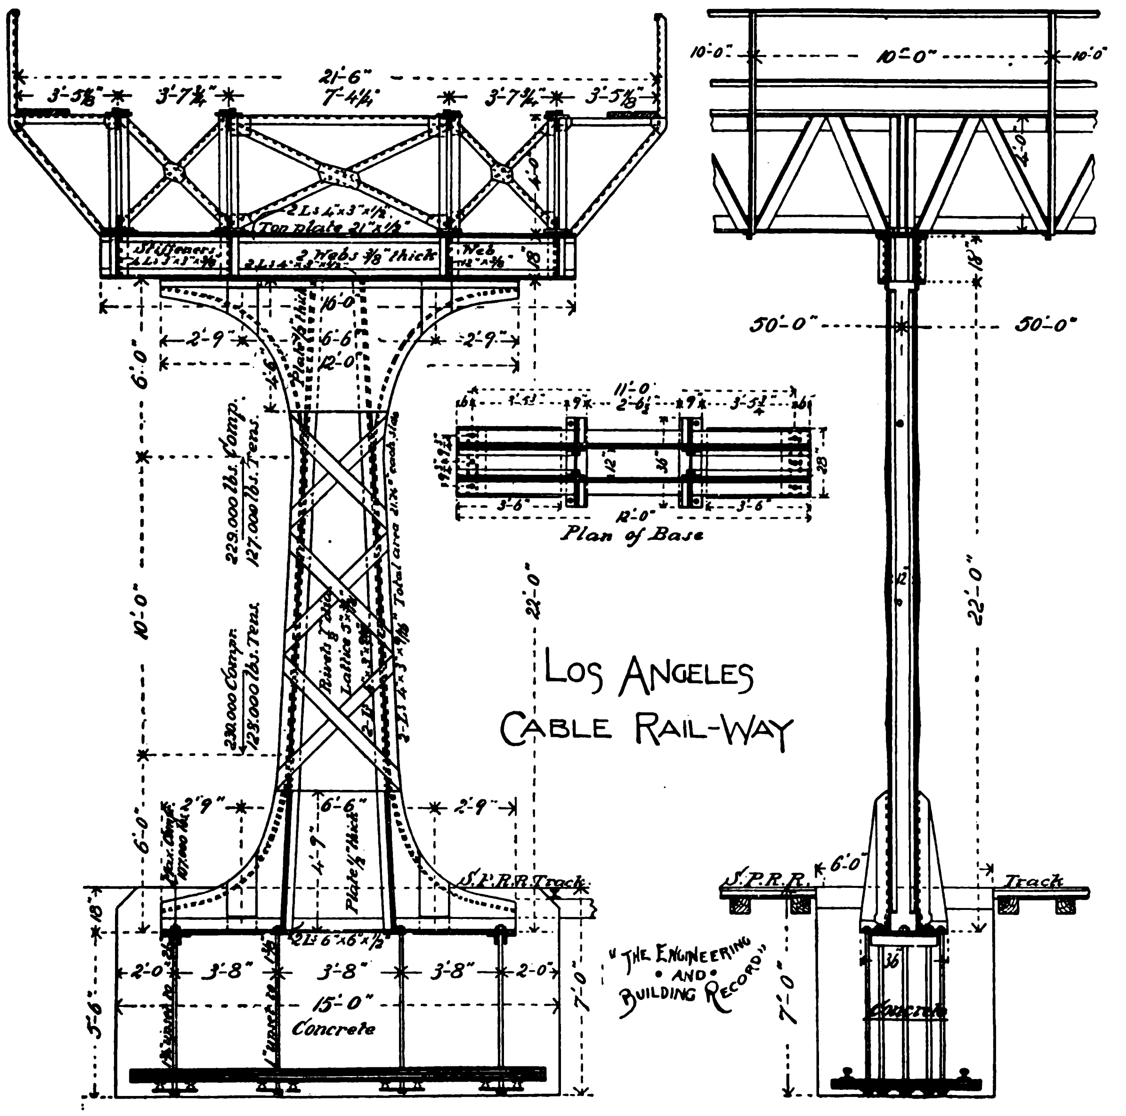
The tests of distribution and rate of flow are made under a head of ten feet, as well as under high pressure. A barrel is mounted so that the level of water in it is 10 feet above the center of the connection into which the sprinkler is secured. A large valve is placed directly under this barrel, by means of which the water may be admitted to the sprinkler without producing a throttling action. A 1-inch ordinary steam pipe screws into a bushing fitted in this valve. At a distance of 10 feet below the surface of the water a horizontal length of ¾-inch pipe, 10 feet long, is connected by means of an elbow. The reason for employing the lengths of pipe given above was to connect the head so that the water furnished it should have to travel through about the same length of pipe of a small diameter as it would in the case of a sprinkler connected to system in a building. The sprinkler head connected to the testing apparatus is 8 feet above the floor.

The New York Board of Fire Underwriters requires that the distribution 8 feet below the sprinkler head shall be over a circle whose diameter is 10 feet; that the diameter 6 inches above the head shall be 8 feet, and that the rate of flow shall be greater than one cubic foot per minute.

To measure the diameter 6 inches above the head a graduated straight edge is employed. The observer, standing on the same level as this straight edge, can readily observe the diameter spread over.

In some tests a flat surface has been placed 6 inches above the head to show how the water will be distributed when the head is used under a ceiling. If the water is thrown upward at too great an angle it will not distribute properly if used under a ceiling. All the heads are tested under 20 pounds pressure, as well as that due to 10-foot head.

An additional test that requires much time to arrive at satisfactory conclusions is one for liability to loss by water damage. Many heads are arranged so that they may be tightened up if leakage occurs. This tightening up is liable to bring an excessive strain on the solder joint, which may yield, not immediately, but perhaps one, two or three weeks afterward. It appears that the strain produced a slow, weakening action. This action has often been observed in the heads that were connected to open end pipes filled with water and brine and set aside for three months for the first and second tests, as already explained. Many of the so-called instances in which sprinklers have been opened by the water hammer may have been simply caused by excessive strain on the solder joint.



THE FREEZING PROCESS OF EXCAVATING.

THERE are given below some details of work at Iron Mountain, Mich., referred to in an article on excavating by the freezing process published in this journal May 7. Both description and illustrations are from an interesting article contributed by Daniel E. Moran, C. E., to a recent number of the *Railroad Gazette*. The 27 8-inch freezing pipes used were of ⅜-inch wrought iron, in sections, connected by taper screw joints cut in the thickness of the pipe itself and making flush joints inside and out. Each joint was tested by water pressure as lowered, and when the pipes reached the bottom the 10-inch casing pipes through which they had been sunk were removed by a water jet and the work, conducted up to this point by the Chapin Mining Company, was turned over to the Poetsch-Sooysmith Freezing Company, contractor for sinking the shaft.

A Linde ice machine (ammonia compression type), of 50 tons refrigerating capacity, built by F. W. Wolf, of Chicago, was used, driven by an Allis-Corliss engine, to which it was connected by a shaft carrying a heavy fly-wheel. The engine was 18 by 42 inches, used compressed air at 60 pounds pressure, and developed 55 horse power at 60 R. P. M.

No trouble was experienced from freezing of the brine used (60 per cent. Ca Cb$_2$), except when its specific gravity was below 1.200.

The cold brine was pumped through a set of distributing pipes and regulating valves to the ground pipes. After traversing the ground pipes it returned through a set of collecting pipes, similar in arrangement to the distributing pipes, to the refrigerating machine.

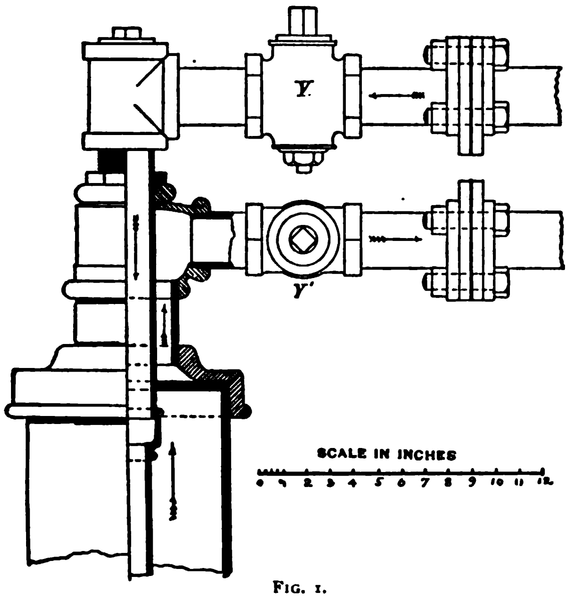


FIG. 1.

The connection of the ground pipe to the delivery and return pump pipes is shown in Fig. 1, where the circulation is indicated by arrows, and a portion of the 8-inch ground pipe and the inside 1½-inch pipe through which the brine is forced to the bottom is shown in section.

The circulation of the brine through each pipe was adjusted by means of regulating valves V and V$_2$ so as to bring the temperature of the return streams as nearly equal as possible. This method of regulation was designed to render the effect of each pipe equal in the event of the conditions affecting the pipes being different. The velocity of the brine in the inner down-flow pipes was 2 feet per second, the brine changing every 25 minutes in the ground pipes.

The connecting pipes above ground were not protected in any way, so that immediately after starting the condensation of moisture from the atmosphere coated the pipes and connections with a snow-like ice, which increased in thickness until some very picturesque effects were produced. The coating, moreover, served as a cheap and effective lagging.

The brine reached the bottom at nearly its initial temperature, so that the lowest temperature, and consequently the greatest freezing effect, was at the bottom of the shaft. With a nearly constant difference of only 1° Cent. between the top and bottom of the pipes there was a marked difference in the distance frozen, as determined at the completion of the work by means of a small trial shaft sunk on the outside of the wall, which showed a nearly uniform batter of about 1 in 15.

The rate of freezing varied in different materials according to the amount of water contained. Several careful experiments gave 17 per cent. of water in the fine sand. Where gravel or boulders were imbedded in the sand this percentage was largely decreased and the distance frozen was correspondingly greater.

It was calculated that the water in the sand consume nearly 80 per cent. of the refrigerating effect. If, then, the sand were replaced in part by material not containing water, the work of freezing would be proportionately reduced.

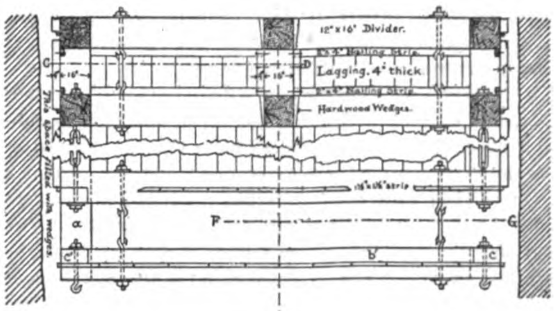

FIG. 3. Elevation and Section.

Losses of the total refrigeration are due to radiation above ground, conduction from subterranean sources of heat, conduction from surface, flow of subsoil water and the cooling of a quantity of material beyond the limits of the frozen wall.

The Iron Mountain sand had a slight tendency to cake and the grains were not clean. Nearly 70 per cent. of a 100-gramme sample (from the center of a lump) passed a 190-mesh screen.

Tests were made during the progress of the work to determine the strength of this material when frozen. Briquette molds were filled with saturated sand and frozen, the resulting briquette being kept at a low temperature until tested. An ordinary Fairbanks cement tester was used for both tensile and compressive tests. The compressive tests were limited by the size of the machine to 1-inch cubes, which were formed roughly by the same method used for the tensile strength briquettes. The tests were made in a cold room, but the temperature of the test pieces was not determined, nor is it known what effect, if any, cooling below 0° Cent. has on the strength of the material. The results were as follows:

	Tensile Strength.
Average of 4 tests	431 lbs. per sq. inch.
Maximum result	491 " "
	Compressive Strength.
Average of 8 tests	575 lbs. per sq. inch.
Maximum	880 " "

When unmixed with gravel frozen quicksand looks like a fine-grained sandstone; it is perfectly homogeneous, breaks with a tendency to conchoidal fracture and is as hard to work as a stone of similar character. When the sand contains gravel or boulders the difficulty of working is more than doubled. There seems to be no tendency of the rounded boulders to pull out of the quicksand, but rather for the break to follow.

Figure 2 is a section of the shaft showing the stratification of the soil and the arrangement of timbering and pipes.

Figures 3 and 4 show the details of the timbering, which was all framed at the surface.

The first and uppermost set of timbers was hung from heavy sticks which extended along two opposite sides of the shaft and were sufficiently long to get a solid bearing at each end 6 feet back from the edge of the excavation.

As the timbering progressed each set was hung by links and screw bolts from the one immediately over it. Only the main timbers and the 4-inch lagging were put in position at first, the cross timbers (or "dividers") not being put in until the timbering was nearly completed, and then in reversed order, beginning at the bottom and working up. The operation of putting in a set was as follows: The set having been framed, assembled and marked above ground, the first pieces sent down were the two opposite ones, *b* and *b'*, Figs. 3 and 4, which were to be hung from the set above, and support in turn the other two pieces, *c* and *c'*, by their halved ends. Pieces *b* and *b'* being in position, hanging loosely by the links and screw bolts, pieces *c* and *c'* were put in place without special care as to exact position. The four corner pieces ("studdles") came next, and then wedging, bolting, spiking, and putting on the lagging.

Between the sides of the excavation and the lagging heavy wooden wedges were driven, and where the material was especially fine hay was also packed in with the idea that it would, when wet, swell and fill the cracks between the 4-inch lagging pieces, and prevent any sand from entering. The only difficulty was to get the last piece in position, and careful fitting was necessary to have it go in tight.

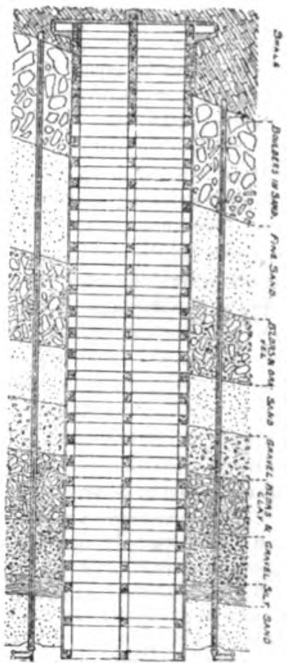

FIG. 2.

The joints between the pieces of lagging were waterproofed by strips of tar paper dipped in hot pitch and held in place by battens.

The timbering followed the excavation closely, chiefly to save the trouble of scaffolding.

The finished shaft was nowhere more than a quarter of an inch out of truth or plumb.

The completed excavation carried the shaft into the ledge from 4 to 10 feet. It was necessary to make a tight connection between the ledge and the lining, and to arrange for the support of the timbering from the ledge. This latter was accomplished in the usual manner by running short drifts into the ledge at the center of each side and putting in extra long and heavy cross timbers. The joint was made by trenching in the bottom of the shaft for the bottom set of timbers and carefully grouting the space between the timbers and the trench. To this bottom course of timbers the next course was fitted and spiked and the space between it and the ledge filled with cement mortar. The gap between the lowest set of open timbers and the bottom of the shaft was in this way filled in with solid timbering.

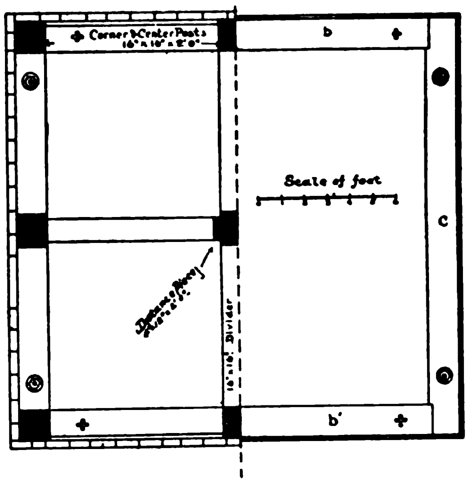

FIG. 4.

Sectional Plan on Line C. D. Plan on Line F. G.

When the timbering was completed steam was turned into the shaft to thaw all ice on the timber, so as to permit the joints in the lining to be made tight with tarred paper, as before described. Finally, water was pumped in up to the level of the water in the soil, and the shaft left to thaw out. The purpose of filling the shaft with water was to equalize the pressure on the timbering during the thawing, which, it was thought, might bring sudden or unequal strains on the shaft.

From trial borings made after the completion of the work it was believed that the quantity of material frozen at that time was bounded by a cylindrical surface, 54 feet in diameter and about 100 feet in depth. This mass of frozen material took a long time to melt, notwithstanding efforts of the mining company to hasten the result. It was not until 50 days after shutting down ice machine, that the ice wall gave way sufficiently to permit water to come into the shaft.

COMPRESSED AIR FOR WORKING ELEVATORS.

THE Popp system of compressed air power transmission at Paris is being steadily extended. According to a recent report the Parisian Compressed Air Company has just introduced an elevator having this motive power, and it is being tried at the Bourse du Commerce and at one or two of the principal hotels. Its main recommendation is said to be that the cost is about one-half that of hydraulic elevators, and that the expense of working is proportionate to the weight of material raised. The principle of the elevator is very simple. The elevator is worked by compressed air, which operates upon water. When the compressed air is admitted it enters a water chamber. The water in the chamber is forced out under the elevator ram or piston, which is driven upwards. On the descent of the elevator the water flows back again into the chamber, so that the action is easy and gradual. By this method the power exerted can, it is claimed, be regulated at will, and the elevators now in use in Paris are employed both for lifting persons and for raising machinery and similar heavy goods. The same company has also laid down an installation in the Bourse du Commerce for refrigerating purposes, the air being maintained at a low temperature by expansion of compressed air.

VALVES FOR WATER AT HIGH PRESSURES.

IN discussing a question as to the best form of valve for water at high pressures, presented at the recent Cincinnati meeting of the American Society of Mechanical Engineers, G. C. Henning referred to the valves used in the emery testing machines in which there was no leakage at pressures as high as 4,500 pounds per square inch. Hammered emery bronze is used for the seats of these valves, the valves proper being steel plugs carefully turned and ground. Both valve and seat are conical, and, according to Mr. Henning, this form of construction has been satisfactorily used under pressures ranging up to 10,000 pounds per square inch. A leather ring is used for packing the valve stem, and the largest size of valve of this kind used had a 1-inch opening.

HOW TO KEEP FROST OUT OF WATER PIPES AND HYDRANTS.*

OUR pipes at Leadville, Col., are laid 6 feet deep, and the frost goes 7 to 10 feet deep. After laying the pipes, and before filling in with dirt, we pack around them with good stable manure, which makes a good warm dirt even after the life is out of the manure. All large rocks and boulders should be removed and not put back in the ditch.

Hydrants should be inclosed around the bottom with a box of 2-inch lumber 2x2½ feet, and 2 feet high without a bottom. A 1½ inch pipe should lead from the box up by the side of the hydrant to blow steam in.

All services are laid in double boxes, the double boxing makes an air-chamber preventing frost from catching the pipes so quickly. One box is 8 inches in the clear and the other 4 inches, and the service pipe is laid in that with a ½-inch pipe running up by the side of the curb-box, and also extending some distance each way in the pipe-box so as to blow steam in.

We have a steam boiler, about four horse-power, mounted on a wagon, which we hitch horses to. We open the hydrants almost every day after the frost gets down, and if they are beginning to catch or freeze, which, with a little experience almost any one can tell, we blow steam down the ½-inch pipe to warm up the bottom of the hydrant. If the 4-inch pipe leading to the hydrant is frozen we take the top off and take the inside barrel out, then we have a heavy ½-inch steam hose which we feed through a 2-inch pipe bent a little at the lower end, and it is very easy to feed it through to the main pipe, cutting out all the ice in a few minutes.

If the main pipe freezes we dig down as soon as possible, drill a 1¼-inch hole in the main and feed in the steam hose either way. Of course it is necessary to shut off the water, and therefore there should be plenty of valves. If taken in time we seldom have a pipe burst. And for service pipes, if we are notified as soon as they freeze, we attach our steam hose to the ½-inch pipe or stop-box and blow steam for a few minutes into the double boxing and it thaws them out. We seldom have a bursted pipe if taken in time. We do not agree to keep service pipes open, but, as a rule, when we have steam up and have the time we make no charge for thawing them out. Our plumbers have similar steamers, only on a smaller scale, to pull by hand, which they use quite extensively, and for which they charge the consumer.

We also have a system of opening and closing valves and opening hydrants to test the different cross streets, by which we can tell if the main pipes are freezing. If so we let the hydrant run for a few minutes and the water will cut the ice out. The temperature of our water is from 33 to 35 degrees, and where it is possible when pumping we turn the exhaust into the sump so as to raise the temperature, which is quite a benefit.

---

* Paper read by C. N. Priddy, Superintendent of Water-Works at Leadville, Col , before the annual meeting of the American Water-Works Association at Chicago, May, 1800.

RECENT WATER-WORKS CONSTRUCTION.

No. XXII.

(Continued from page 360, Vol. XXI.)

NEW WORKS FOR DENVER, COL.

THE general plan of the water-works now being built at Denver, Col., by the Denver Water Company, will be understood from the annexed sketches, which roughtly outline the locations of the reservoirs and pumping-station, the lay out of the delivery mains, and a vertical section at the primary source of water supply.

The works will embrace a submerged dam, or rather caisson, built of timber and designed to intercept the subterranean flow of water under Cherry Creek. The latter is dry except during periods of flood, and the bed rock immediately underneath it forms a depression about 40 feet deep, making the depth below the surface of the ground about 70 feet. The section (Fig. 2) explains the formation There is a steady slope up to the mountains at the right, and the subterranean flow of water after having reached the depression under Cherry Creek, will be caught by the caisson and delivered into the pump shaft at the right. The length of the caisson will correspond with the width of the depression, measuring 700 feet, and will be about 16 feet wide. Its height from bed rock to the surface of the bed of the creek will be from 60 to 70 feet, which will allow an ordinary flow or freshets to pass over its top without damming up the creek. The pump shaft will, for the present, contain two sets of triple expansion pumping-engines, built by E. P. Allis & Co., of Milwaukee, Wis., each having a daily pumping capacity of 15,000,000 gallons against a head of 200 feet. A third set will be added in the near future. The pumping station will be at Sullivan Station, about seven miles from the city of Denver.

G - Duplicate Future 48" Line.

The work of excavation for the pumping station is now progressing. It will be 150x70 feet, and its foundation will be in bed rock. The walls will vary from seven feet at foundation to two feet at line of water table. The pump house surmounting these foundations will be a stone building, the design selected being that submitted by Albert Kahn, of Detroit, Mich., in the pumping station competition of THE ENGINEERING AND BUILDING RECORD, published in the issue of March 29, 1890.

The construction work is now in progress with a force of 50 men and 25 2-horse teams, which will be increased to 500 men within 30 days, and whose work will be supplemented by improved dredging machinery. The present steam dredge is mounted on a scow and will be used to a depth of 30 feet, after which the timber dam will be put together and sunk, when the dredging will be done from the interior of the caisson by means of a vertical dredge operated by an electric motor.

The pumping engines will have a guaranteed duty of 130,000,000 foot-pounds, and the first set is to be ready for operation on April 1, 1891. The second set is to be complete by October 1, 1891. The water ends of the engines, as will be understood, will be at the bottom of the pump shaft, on a level with the bottom of the submerged caisson, and will thus be submerged, while the steam ends will be above on the pump-house floor.

The reservoir will be at an elevation of 398 feet above the City of Denver and that to be first completed, marked Basin No. 1, in Fig. 1, will have a capacity of 70,000,000 gallons. The available water pressure, it is understood, will be sufficient to reach the highest buildings of Denver. The quality of the water is said to be excellent and its temperature exceedingly low. The cleaning of the reservoirs, when necessary, will be effected by special blow-off valves and outlets in the bottoms, the latter being arranged to form a number of large pockets intended to serve as collecting basins for the mechanically suspended impurities. The blow-off valves will be located at the lowest points.

The accommodation for the working force at present comprises a boarding house 200 feet long, two stories high with a dining room 100 feet by 30. Contracts have also been let for three brick dwelling houses and a brick storehouse, which will be permanent structures.

There are now being made two switches from the Denver, Texas & Gulf Railroad at Oakesdale, ten miles from Denver.

Capt. Edward Ruger, chief engineer, is in general charge of the work ; W. F. Hawes is assistant engineer ; Capt. H. N. King, superintendent of construction; T. A. Taylor, general foreman.

The estimates for the work call for an expenditure of about $500,000.

For the above particulars THE ENGINEERING AND BUILDING RECORD is indebted to Mr. W. A. Underwood, of The American Water-Works Company, New York.

THE CONTAMINATION OF STORAGE WATER.

IN discussing a paper entitled, "Contamination of Storage Water on the Pacific Coast, and the Palliatives Resorted To," presented by L. J. LeConte at the recent Chicago meeting of the American Water-Works Association, Professor Albert R. Leeds, among other things, said :

Mr. LeConte brings into prominence the unusual physical conditions prevailing upon the Pacific Coast; and, more particularly, the climate. He thinks that we on this side have no adequate comprehension of the difficulties growing out of these conditions. Mr. LeConte says that they are compelled to rely for their water supply upon the rain which falls in their winter season between the months of November and May. After this period for a period of six months they have no rain, and their storage system must be regulated accordingly. It is very usual for a whole winter to pass, and sometimes more than one, without any rain. The period of drought may extend to 600 days, and they must have reservoirs to give them a water supply reaching over 900 days, or more than two years' supply. The city of San Francisco has three reservoirs on a scale of which we have little experience on the Atlantic Coast. One of these reservoirs has a capacity of 10,080,000,000 gallons; the second 6,690,000,000 ; and the third 3,830,000,000. The amount of water supplied to the city from the first two reservoirs is 9,000,000 gallons a day, or only a little more than 1-1,000 part of their united capacity.

The city of Oakland, he further says, has a reservoir of 4,300,000,000 gallons, supplying 22,000,000 gallons per diem, or about 1-200th of its capacity.

In a very lucid manner he describes the life history, if I may so call it, of the water as it falls from the clouds, is impounded in the reservoirs, flows down from the aqueduct, and finallly reaches the consumers. He divides this life history into three stages: First, the period of collection extending through the winter season up to the end of May. During this time the water is good, notwithstanding some light silt or mud is carried into it by 48 winter floods. He makes the important observation that up to the end of this period of collection the temperature of the surface water is 48° Fahr., and that of the bottom water 50, and since the warmer water is below and the colder at the top, there goes on during this first phase of the life history a constant circulation.

The second phase, he calls the period of fermentation. This sets in about the end of May. The surface of the water now acquires a temperature of 62 degrees, while the bottom retains its temperature of about 50. As a physical consequence the circulation ceases, and this period of fermentation is also a period of stagnation. This second phase of the life history is attended with a growth of phenogamous plants; that is to say, ordinary fresh water plants, plants capable of giving up oxygen, assimilating carbonic acid, supporting fish life, etc. Later, the era of fermentation is marked by the rising of bubbles all through the water, which consist of carbonic acid gas and carburetted hydrogens. As these gases increase in quantity, the dissolved oxygen diminishes and the vegetation changes its character. It is no longer phenogamous, it becomes cryptogamous: the familar plants which flourish in lively water disappearing, and the more obscure forms of vegetable life, the algæ, making their appearance.

Now comes another and more tragic phase of the life history: First, the youthful life with its beauty, then its development, then approaching decay. Now, there has arrived the last phase, which is that preceding death, and this last phase is one of putrefaction. When this has arrived the gases have changed their character. The oxygen has largely disappeared and carbonic acid gas, carburetted hydrogen and sulphuretted hydrogen have taken its place. In the phase of putrefaction, decay is going on, and whenever decay occurs in the absence of oxygen it is dangerous and means death; it means the formation of septic poisons, fatal to both vegetable and animal life.

This period of decay ends with the close of October. In November the life history enters again upon a new cycle. The frosty nights set in as soon as the water becomes chilled. The chilled water sinks to the bottom, and once more circulation of the water in the storage reservoirs takes place with consequent alterations and changes. Curiously enough, at this point, the water as shown by analysis is at its worst. This is due to the circulation having been established once more. The warmer water rising from the bottom, along with the gases, brings mud and organic impurities to the surface. Mr. LeConte emphasizes the fact, that while the water in the storage reservoirs is very bad, yet as it passes down the open flumes and aqueducts leading from the reservoirs, being in contact with the air in these open conduits, its quality continues to improve progressively until by the time it reaches the surface reservoirs it is at all times much better than the water in the impounding reservoirs. He further discriminates in this connection between the changes taking place and the resulting quality of the San Francisco water and the city of Oakland water. Both are provided with enormous impounding reservoirs, but the San Francisco water comes down through open conduits and passes through screens placed at the service reservoirs within the city limits. The city of Oakland water, on the other hand, passes through screens placed near the storage reservoirs, and then flows many miles out of contact with air before it is delivered to the consumers. It results from these differences that the quality of the water in San Francisco is far better than the city of Oakland water. Furthermore, in regard to the city of Oakland, an additional source of the offensive taste is in the pipe system. During the entire putrefactive stage in the storage reservoir the water in the pipes supplying the consumer is always bad. Mr. LeConte attributes this offensiveness to the mud in the surface pipes and finds it to be so much the worse as this mud is excluded from the air.

In concluding this resumé of the paper, I will bring to your attention the palliatives proposed by Mr. LeConte. His first palliative consists in the removal of the mud from the reservoirs. He proposes to effect this removal by means of a pipe let down to the bottom through which the mud should be pumped.

Secondly, the accumulation of the mud in the service pipes should be remedied by previous subsidence and sand filtration.

I have now given you as fair an idea of the contents of this valuable paper as I could from my recollection of it as read.

I am sorry that I have no personal knowledge of the climatic conditions prevailing on the Pacific coast. But the troubles which Mr. LeConte speaks of are similar to those which baffle and perplex all of us, perhaps more than anything else in connection with the palatability of particular water supplies. To show that these troubles are very common in the Middle and New England States, I would mention that in the summer of 1874, the state of affairs Mr. LeConte speaks of as chronic in these Californian storage reservoirs, occurred over the whole of the northern part of New Jersey. Mr. Owen, our fellow member, said to-day, that, in accordance with the recommendations of the Water Commission of New Jersey, the whole of the water supply which falls upon the Passaic water-shed of northern New Jersey, and which is 900 square miles in area, is to be parcelled out, and so many million gallons are to go to the city of Newark, so many to Jersey City, and so on. But, while the remark made by Mayor Haynes, of Newark, that this water is of great purity, is true of the water in its ordinary condition, yet, in the natural impounding reservoirs, which are the lakes all through this water-shed, the same trouble that Mr. LeConte speaks of frequently occurs. In the summer of the year 1874, if I recall the date correctly, there was not a lake in this water-shed which did not present the same phenomena, and went through the same changes of fermentation. The fish were affected by it, a vast number dying and rising to the surface, being killed by the poisons generated in this process of putrefaction. The country people recognize the recurrent character of this aquatic disorder, and denominate it the "purging of the water."

I spoke of New England. At Athol, Mass., for instance, the water is taken from a natural impounding reservoir, and every season it goes through the same cycle. Not only the period of fermentation and of algæ, but of putrefaction attended by an intolerable stench. At Springfield, Mass., the Ludlow reservoir covers 550 acres, and they have tried a number of palliatives, especially gravel and charcoal screens, but without success. The water supplies of Newburg, on the Hudson, and of very many other towns in the Middle States have their like periods of fermentation and putrefaction.

It is a mistake to suppose that troubles from aquatic vegetation take place only in the warm season. Our friend, Mr. Tubbs, will sustain me in the statement that in connection with the water supply taken from Hemlock Lake at Rochester, they have had trouble in winter quite as bad as in summer, due to the development of certain forms of algæ. There are certain kinds of algæ that will grow on the ice, and they have suffered on this account at Rochester in the month of February. The same thing is true of the water supply of Philadelphia in the winter of 1882. The water supply at Philadelphia comes mainly from the Schuylkill River, which has a daily flow of 300,000,000 gallons. At that particular season, the river was coated with ice from Pottsville and the mining district down to the Fairmount Pumping Station. Many of you who visited the Centennial in 1876 will probably recall that there were a great many cases of typhoid fever among the visitors at Philadelphia at that time. The origin of the typhoid fever prevalent among the Centennial visitors was attributed to the polluted water of the river Schuylkill. The examination of the water at Philadelphia in 1882 showed that it was very impure, but the cause of the offensive taste and odor was not revealed until the analysis was extended to the examination of the gases dissolved in the water. This examination showed that the oxygen had disappeared, and its place had been taken by carbonic acid and carburetted hydrogen. These changes had come from the putrefaction of the sewage contained in the Schuylkill water, beneath the ice, and consequently out of contact with the air.

I shall have a few words to say with regard to the nature of the remedies that appear to be indicated. Mr. LeConte dwells upon the importance of the removal of the mud from the bottom of the reservoirs, and on keeping it out of the pipes by subsidence and filtration. In reference to the former recommendation, I would add the importance of preventing the process of fermentation and putrefaction in the reservoirs, by eliminating the dissolved carbonic acid and carburetted and sulphuretted hydrogen by means of excess of oxygen. These two objects are being carried out in a number of places by artificial aeration. Water, after this treatment, does not require preliminary subsidence. Its suspended mineral matters can be completely removed by precipitation and filtration, which at the same time remove all other particles however minute, including the spores of bacterial and cryptogamic life.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department.* Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

HOW TO PROPORTION VAULT WALLS AND ROOF.

"ARCHITECT" writes: "I am somewhat puzzled over the following problem, and venture to ask your assistance in its solution.

An underground vault in a public road is 25 feet wide, 300 feet long and 10 feet deep, and will have a covering of 7 feet of earth. Supposing the roof to be of I-beams with flat 8-inch brick arches and sidewalls of brick, for what strains should the roof and sidewalls be proportioned?

It is assumed that 15-inch I-beams, 4-foot centers will be sufficient, supposing the load to be 250 pounds per square foot. It seems to me that this is incorrect, as the filling may weigh 100 to 110 pounds per cubic foot, giving for 7 feet in depth 700 to 800 pounds per square foot which, with the weight of brickwork 125 pounds $\times .7' = 90$ pounds per square foot, and 1-foot length of I-beams $\frac{200 \text{ pounds}}{3} = 70$ pounds, making in all about 1,000 pounds per square foot. There is also no allowance for live load.

The side walls sustain a load per lineal foot of ½-span × weight per square foot on roof $= 13 \times 1{,}000 = 13{,}000$ pounds, and I suppose should be treated as a surcharged retaining wall, because the banks are very likely to crack when the sheeting is drawn, and in accompanying diagram, in which I attempt to treat the solution graphically. I assume that the slope must be considered as about 1 to 1. After applying forces, surcharge, etc., I find resultant pressure lies just inside foot of wall; also the triangle above the surcharge appears to act on the roof. Have I properly indicated the amount and point of application of this force? It is not included in the roof load or any other. What is effect of roof to prevent overturning of wall? [See Fig. 1.]"

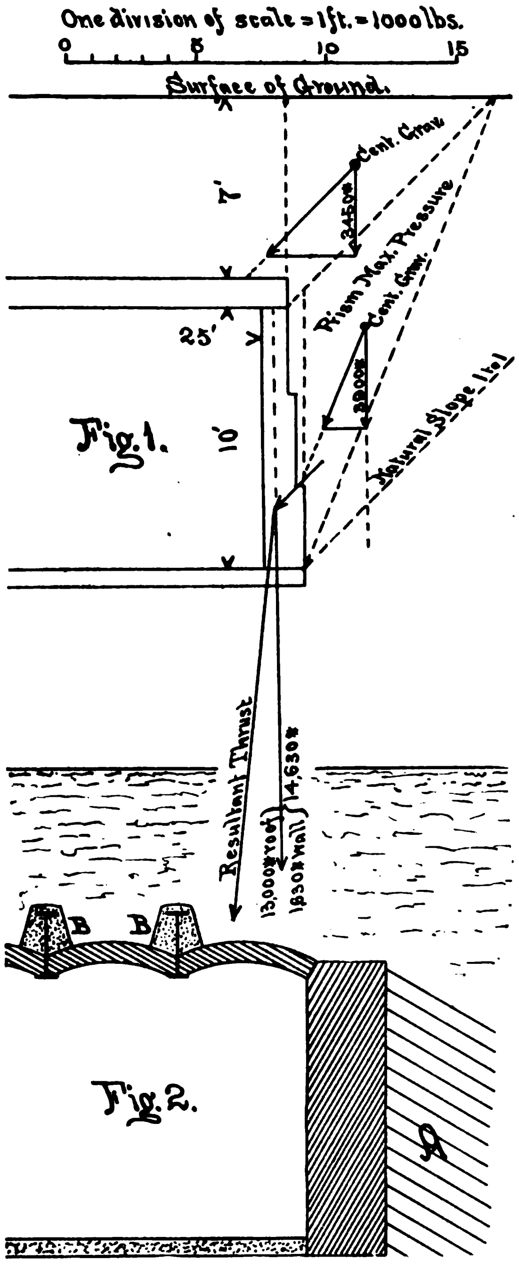
[The assumed load of 250 pounds per square foot on the roof of the vault is, as our correspondent has pointed out, altogether too small, and 1,000 pounds per square foot, as he suggests, is probably pretty near the truth for the dead load, although he has neglected to divide his weight of I beams by four as would be necessary with beams spaced 4 feet to centers. To carry this load with rolled beams would require 20-inch heavy I-beams about two feet apart and weighing about 45 pounds per square foot of roof. Riveted girders would be stiffer and weigh less per square foot and cost less per pound, and could be put enough further apart to considerably reduce the labor of turning the arches. Let us see how large they would have to be if spaced five feet to centers. The dead load above assumed of 1,000 pounds per square foot would give a maximum shearing strain of $\frac{1}{2} \times 1{,}000 \times 5 \times 25 = 62{,}500$ pounds and a maximum bending moment of $\frac{1}{8} \times 1{,}000 \times 5 \times 25 \times 25 = 390{,}625$ foot-pounds. The heaviest live load would probably be a 15-ton road-roller, and of this not more than one-half could very well get on one girder at a time, though it might rest on it near one end, and so give a maximum shearing strain of, say, 12,500 pounds. The maximum bending moment from this load at the center would be $\frac{1}{4} \times 15{,}000 \times 25 = 93{,}750$ foot-pounds.

From live and dead loads combined the maximum shear would therefore be $62{,}500 + 12{,}500 = 75{,}000$ pounds, requiring, at 6,000 pounds per square inch, 12½ square inches in the web plate, which, if 24 inches deep, would give a thickness of, say, 0.5 inch, or if 30 inches, 0.4 inch.

The total bending moment would be $390{,}625 + 93{,}750 = 484{,}375$ foot-pounds, giving a chord stress for a girder 24 inches deep of, say, $480{,}000 + 2 = 240{,}000$ pounds, and requiring chord sections, at 12,000 pounds per square inch, of 20 square inches, or, if 30 deep, of 16 square inches. The total section of the 30-inch girder would, therefore, be $12 \times 16 \times 16 = 44$ square inches, and its weight per square foot of roof supported $\frac{1}{5} \times 44 \times 3.33 = 29$ pounds, which would be increased somewhat by rivets and stiffeners, but would not much exceed two-thirds the weight of the rolled beams per square foot, especially as something could be saved by reducing the chord section toward the ends. These girders would weigh about two tons apiece. In view of the fact that a central support would reduce the shearing stress by about 50 and the bending moment by about 75 per cent., with a corresponding reduction of metal in the girders, it would evidently be well to provide such a support if possible. Light 15-inch beams about four feet apart would then answer the purpose, and would weigh about 12½ pounds per square foot of roof.

In calculating the pressure on the side walls our correspondent has not hit the mark so closely. In the first place, no ordinary material can be depended on to stand continuously at a slope of 1 to 1, certainly not if it has to be sheet piled when excavated, as he intimates. A slope of 1½ to 1, or 33⅔ degrees, is as much as it is safe to calculate upon. A glance at the diagram is sufficient to show that merely as a retaining wall the structure would not support the pressure of the earth, but, fortunately, it does not have to act in that way. The wall, or rather, for convenience, we will say, any portion of it a foot long, is in the condition of a loaded column subjected to a lateral pressure, or, perhaps, it may be more conveniently treated as a weightless beam supported at both ends and subjected simultaneously to end pressure and to the action of a distributed load. This load is the pressure of the earth, which varies directly as the depth, and inversely with the angle of repose of the material. With 33⅔ degrees, as the assumed angle of repose, the horizontal pressure at any point on a vertical plane will, according to Rankine, be equal to 0.29, say 0.3, of the vertical pressure of the earth at the same depth. If the top of the wall is 8 feet below the surface, and we take the material to weigh 110 pounds per cubic foot, then the horizontal pressure at that point will be $8 \times 110 \times 0.3 = 264$ pounds per square foot; at the bottom of the wall, which is 10 feet lower, it will be 594 pounds per square foot, and will vary uniformly between giving an average pressure of 429 pounds, or a total pressure per lineal foot of wall of $10 \times 429 = 4{,}290$ pounds. The variation in the pressure will slightly increase its bending effect, but it will also slightly lower the point of greatest bending moment, and without going into any exact calculation, its effect will, perhaps, be fully allowed for by calling the pressure 4,300 pounds, and uniformly distributed. This, on a beam supported at two points 10 feet apart, would give a maximum bending moment of $\frac{1}{8} \times 4{,}300 \times 10 \times 12 = 64{,}500$ inch-pounds.

It now remains to find how thick the wall must be in order that the tensile stress at its inner face may be reduced to safe limits or altogether eliminated. In this case the tensile stress will be reduced and the compressive stress increased by the load on the top of the wall as well as by the weight of that part of the wall itself which is above the point of maximum bending moment. The weight of the earth and masonry above the spring of the arches has been taken at 1,000 pounds per square foot, and if we take the masonry to weigh 120 pounds per cubic foot and the point of maximum bending moment to be at half the height of the vault, or five feet below the spring, the weight of wall to be added will be 600 pounds per square foot, or a total of 1,600 pounds per square foot, or 11 pounds per square inch.



· VAULT WALLS & ROOF.

On the side walls the load per lineal foot from the roof and earth would be $12\frac{1}{2} \times 1{,}000 = 12{,}500$ pounds. This would give a load per square inch on a 24-inch wall of 43 pounds, to which should be added the 11 pounds already allowed for the weight of the upper part of the wall and of the earth above it, making 54 pounds in all. The bending moment of 64,500 inch pounds per lineal foot would give in a 24-inch wall a maximum stress of 56 pounds per square inch, which, combined with the longitudinal stress just found, would give at the face of the wall a tensile stress of $56 - 54 = 2$ pounds per square inch, and at the back a compressive stress of $56 + 54 = 110$ pounds per square inch. The material can easily bear twice this compressive stress, and the tensile stress is so small that it may be safely neglected, especially as it is likely to be still further reduced by the bearing of the beams not being over the middle of the wall either originally or in consequence of their spring when loaded, which would bring it nearer the inner face.

The end walls do not carry so much of the roof load, having only one-half of one arch to carry, or $2\frac{1}{2} \times 1{,}000 = 2{,}500$ pounds per lineal foot, but as this is all carried at the spring of the arch it will produce at least twice as much compression at the face of the wall as if uniformly distributed. On a 36-inch wall, therefore, this would produce a compressive stress at the face of $2 \times 2{,}500 \div 432 = 12$ pounds per square inch, to which must be added the 11 pounds as before, giving 23 pounds of compression. The bending moment will produce in a 36 inch wall a maximum stress of 25 pounds per square inch, so that at the face of the wall there will be a tensile stress of $25 - 23 = 2$ pounds per square inch, and at its back only the 11 pounds per square inch due to the superincumbent earth and the upper half of the wall.

The thicknesses of 24 and 36 inches thus found are probably quite ample, as walls of such dimensions could hardly fail by bulging, after the mortar had hardened, without exerting a positive arch action that would oblige them to lift the entire roof before they could give way. It is, therefore, probable that a thickness of 32 inches would prove sufficient for the end walls, and in fact the whole problem is one involving so many considerations that while it is well to figure out the pressures and thicknesses as a guide in forming a conclusion, the trained eye and judgment of the engineer will in the end be found to be a better dependence than calculation alone.

It is obvious, that as these walls depend mainly for their stability on their superincumbent load and the support they receive at the top, that the roof should be finished and loaded and the mortar allowed some time to harden before any lateral pressure from the filling is permitted to come upon them, and to further this object it may be better not to draw the sheeting but to let it support the bank as long as it will.

If there is room to do it the horizontal pressure of the back-filling may be materially reduced by compacting it in layers inclined from the wall as shown at A, Fig. 2. The upper flanges of the girders or beams should be covered with concrete, as shown at B, Fig. 2, so as to prevent corrosion in the damp earth, and if absolute water tightness is desired it would be well to cover the whole roof with several alternate layers of roofing felt and asphalt.

If the side walls could be lowered a couple of feet or so, and made thick enough to act as abutments, the vault could be conveniently spanned with a 24-inch arch of say 5-foot rise. This would avoid all iron work and be more easily made tight, and by smoothing off the earth in the middle to act as a center while turning the arch, and removing it at the ends after the arch was completed the expense of wooden centering would be saved, and the cost of the entire work would be probably much reduced. It would be well to make a careful estimate of the comparative cost of these plans before proceeding with the construction.

If our correspondent prefers to proportion his work according to the ordinary rules of retaining walls he should look up the subject a little more carefully and need give himself no anxiety about the triangle of earth above the surcharge. The wall can only act as a retaining wall before the roof is on, and in that case the triangle will quickly slide off, or if the earth is so compact that it will preserve its position there will be no lateral pressure on the wall.

We have answered this question at some length as containing some points of general interest, and the thickness of vault walls, though something which has often to be determined, we do not remember to have seen discussed before. As a rule, however, such questions should be referred to a competent consulting engineer, and our correspondent will find the professional cards of several of these gentlemen on the last cover page of this journal. It will probably be wiser for him to get one of them to apply the principles above stated to his particular case than to attempt to do it himself.]

AT a recent meeting of the Montreal City Council, it was stated that there were only four water main manufactories in Canada, that in some recent purchases for the city only two of them were asked to bid, and of the two one was unable to supply the pipe, and so the contract was let practically without competition. Importing pipes was suggested, but there was no action in regard to it.

THE AVON, MASS., WATER-WORKS.

IN the recently issued report of the Board of Water Commissioners of the town of Avon, Mass., the Engineer, Louis E. Hawes, describes the main features of the system of water supply, on which work was commenced August 15, 1889.

The system is what is known as a pumping system, with a compensating reservoir or stand-pipe for storing water between periods of pumping, which, in consequence of the small amount of water that will be used in the town for some time, will occur daily in small quantities, or at longer intervals as the desirability becomes apparent. The system comprises a source or supply well, pumping plant, reservoir and distribution piping with its stop-gates, fire hydrants and service connections. The supply well is circular in form, has an average diameter of 20 feet, is made of heavy rubble masonry laid dry, and lined with a 12-inch brick wall, laid in hydraulic cement. The brickwork starts at a point 6 feet from the bottom, leaving the stonework to that height open for the free percolation of water. The whole rises several feet above the surrounding meadow, the surface above the well being graded to meet it, and is surmounted by a conical roof, with a suitable entrance to the interior. The well is 22 feet deep, with an overflow 4 inches from the top, to which point the water rises and escapes, although 3 feet above the elevation of the original spring, thus storing the water higher. A 10-inch suction pipe connects the well with the pumping machinery.

The pumping plant comprises a horizontal tubular boiler, a duplex compound condensing pumping engine, an air pump and condenser, a boiler-feed pump, and the necessary piping, fixtures, gauges, etc. The boiler is 13 feet long and 54 inches in diameter. The pumping engine has steam cylinders 9 and 16 inches in diameter, water cylinders 9½ inches in diameter, with a 12-inch stroke for all. It is provided with ample air chambers and an air-charging device, has a counter to record the revolutions of the engine, and is so arranged in its connection with the condensing apparatus that it can be run non-condensing, exhausting into the atmosphere. The engine is capable of pumping 36,000 gallons per hour, at a piston speed not exceeding 95 feet per minute, the lift from engine room to high water in the reservoir being 167 feet, or a total average lift from the well of 177 feet, exclusive of friction. The boiler feed pump is so arranged that cold water can be pumped from the well, taken directly from the street main, or hot water pumped from the hot well, always, however, passing through the heater before going into the boiler.

The force main from the pumping station is 8 inches in diameter part of the way, and is then enlarged to 10 inches, continuing this size to the reservoir which it enters at the bottom, rising to a height of 84½ feet, so that water is admitted to the top of the reservoir, and by an automatic arrangement drawn from the bottom, thus insuring complete circulation.

The foundation of the reservoir is 22 feet in diameter and 6½ feet deep, built of rubble stone and cement laid solid, with six anchor plates imbedded below, and six hammered bracket stones set in the top for the anchor bolts to pass through. A tunnel lined with brick extends from the outside to the middle allowing the passage and inspection of the leading main. The reservoir upon this foundation is made of wrought-iron, and is 20 feet in diameter by 90 feet high, made up in sheets thoroughly riveted together. There is a ladder inside and out and a manhole near the bottom. The iron of the bottom and lower 20 feet is half an inch in thickness, the next 20 feet seven-sixteenths, the next 20 feet three-eighths, the next 15 feet five-sixteenths, and the upper 15 feet quarter of an inch thick, which gives a factor of safety of 4.15 at the bottom, four being considered ample. For every foot in height the reservoir contains 2,356 gallons, and when full to high-water mark, which is within 3 feet of the top, holds 205,000 gallons.

The distribution piping is cast iron. The 10 inch pipe weighs 60 pounds per foot, the 8-inch 45 pounds, and the 6-inch 30 pounds per foot, every length being certified to have received a pressure test of 300 pounds to the square inch before leaving the foundry.

IN Toronto, Ont., local improvements paid from special assessments instead of the general city fund—pavements, sidewalks, etc.—will have 10 per cent. added to their cost to cover engineering and clerical expenses connected with them. This will relieve the general taxpayer from all burden of improvements of the kind.

DOMESTIC PLUMBING & HEATING LIGHTING & VENTILATION ENGINEERING

PLUMBING IN THE HUDSON RIVER STATE HOSPITAL

A GENERAL description of the plumbing system in the New York State Hospital at Poughkeepsie was published in this journal December 25, 1886, accompanied by details of traps, etc., of the pipe fittings in one shaft, and of a brick and stone receptacle in the foot of the shaft which received the discharge from the soil and waste pipes, and emptied into the sewer. Since that article was published other buildings have been added to the institution, and some changes developed in the plumbing, as will be seen in the accompanying illustrations of pipes in the new Surgeons' House.

Figure 2 is a section through the toilet room, and Fig. 1 is a section and elevation at Z Z in Fig. 2. Each trap has the usual back-air vent pipe A that connects with the upper part of the soil pipe, and another independent pipe B extending above the roof, connected to the house side of the trap and serving as a local vent. H H, etc., are handholes with screw caps. C C is a section of the 6-inch pipe and fittings that receives the discharge from the waste and soil pipes and empties into the sewer. It replaces the brick receptacle A B, shown on page 91, Vol. XV, and is not trapped, it and the connected sewer being considered thoroughly aired by the pipes D D, etc. E is a water pipe, which is carried through the same shaft, but is not directly connected with the drainage system. In this case but one set of fixtures is connected to the stack of pipes, but in other new buildings at the Hospital there are two or three sets of fixtures, at different stories, on the same vertical pipes, although the arrangement is substantially the same as shown here.

The plumbing in the Surgeons' House was arranged by Dr. J. M. Cleveland, Superintendent of the Hospital.

NATIONAL PLUMBERS' ASSOCIATION MEETING.

THE eighth annual convention of the National Master Plumbers' Association will be held at Denver, Col., June 17, 18 and 19.

PLUMBING • IN THE • HUDSON RIVER HOSPITAL

FIG. 1

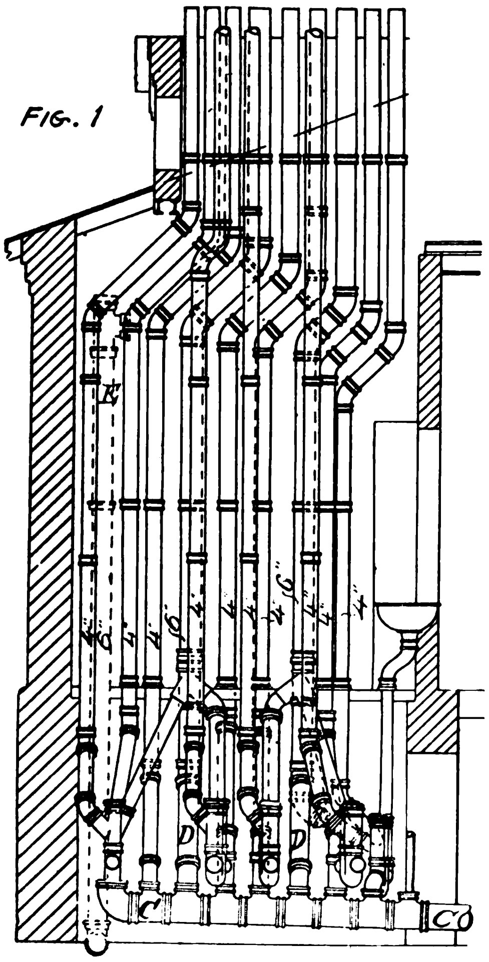


FIG. 2

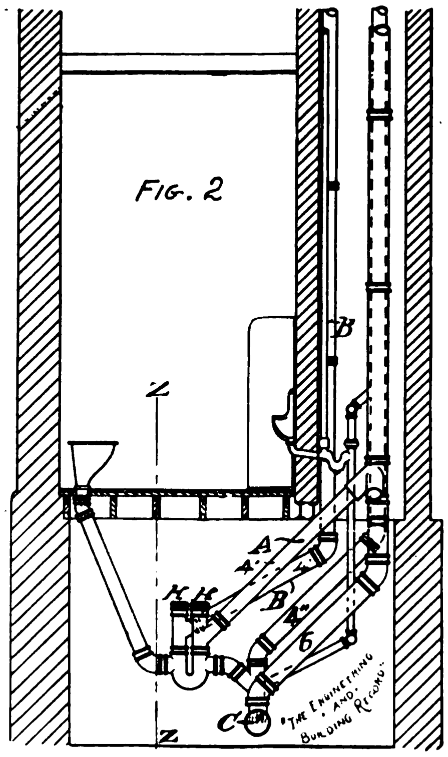


NEED OF OFFICIAL INSPECTION OF HEATING APPARATUS IN BUILDINGS.

BEARING further on the above subject, referred to in THE ENGINEERING AND BUILDING RECORD of May 3, 1890, the following extracts from the "Ordinances of the Building and Health Departments of the City of Chicago" are given:

1070. Hot air, hot water, steam or other furnace, whether brick or metal, shall be kept at least 10 inches and the smoke flue at least 20 inches, off from any unprotected woodwork. All furnaces shall be placed on foundations of brick or stone, with proper hearths, of incombustible material, at least 24 inches wide in front of the ash pit. All hot air conductors that are placed within 10 inches of any woodwork shall be made double, one within another, with at least ½-inch space between the two. All hot air registers shall be set in incombustible borders not less than 2 inches in width; all such borders shall be firmly set in plaster of paris; openings in floors for registers shall be lined with bright tin to receive the register boxes, the lining to be kept at least 1 inch distant from such register box. I. C. or I. X. bright tin shall be used in the construction of all hot air flues and their appendages.

1079. Floors under all stoves shall be protected by a covering of incombustible material. Stoves shall be kept at least 20 inches, and their smoke pipes 12 inches from any unprotected woodwork.

1080. The woodwork of all boiler houses and boiler rooms shall be kept at least 6 feet from the boiler, and 4 feet from the breeching or smoke conductor, and 1 foot from the dome of the boiler, unless such woodwork is properly protected with incombustible material, and then there shall be at least 2 feet space from the boiler or smoke pipe and the protection.

1081. The floors of all rooms, when containing stationary boilers, shall be made of incombustible materials, 5 feet on all sides, and at least 8 feet in front of any boiler.

1082. When portable boilers are used on wood floors of any building, such wood shall have a close protection of incombustible material, not less than 6 inches thick, covering all the space under the boiler and projecting not less than 2 feet on the sides and rear, and 6 feet in front, with an air chamber of not less than 2 inches formed in such protections. Hollow tiles, properly laid, may be used for such protection.

1086. No unprotected heater or movable light shall be kept within any room or building wherein hay or straw, or any highly inflammable articles are kept or stored, the least protection in such cases shall be a permanent surrounding wire screen with meshes less than ¼ of an inch.

1087. Steam pipes shall be kept at least 2 inches from all woodwork, otherwise they shall be protected by a soapstone or earthen ring or tube, or rest on iron supports.

1088. No pipes shall be let into the joists or beams of any floor to a greater depth than 2 inches, and not more than 3 feet from the ends of the joists or beams.

1096. Any chimney not forming a part of a wall shall rest upon the ground with proper foundation, and in no case shall any chimney rest on or be supported by framework, beams or posts of woodwork of any description.

The ordinances of the city of Boston contain the following specifications:

72. The shell of all flues for brick ranges, boilers, furnaces and ovens shall hereafter be of brickwork, 8 inches thick, or its equivalent, to a height of 25 feet above such ranges, boilers, furnaces, or ovens.

73. Ranges or boilers shall have the outside of the flue to the same exposed without covering, or, if plastered, shall be plastered on the outside, directly upon the bricks, up to the ceiling of the room, and no woodwork shall be placed on the outside of the same.

74. All floor timbers, headers and trimmers of every brick building hereafter erected or altered, in which a chimney is to be built in a brick wall, shall be placed distant at least 2 inches from the outside of every chimney flue, and the space between such timbers and the brickwork of chimney shall be closed by a proper fire stop of incombustible material.

75. All hearths shall be supported by trimmer arches of brick or stone, or be of single stones, at least 6 inches thick, and supported entirely by iron beams, one end of which shall be securely built into masonry of chimney or adjoining wall. The brick jambs of every fireplace, range or grate opening must be at least 8 inches wide, each, and the backs of such openings must be at least 8 inches thick, to at least 2 feet above such openings. All such hearths and supports shall be at least 12 inches longer than the width of such openings, and at least 18 inches wide in front of the chimney breast. The brickwork over all fireplaces and grate openings shall be supported by proper iron bars, or brick or stone arches.

76. If any chimney, flue, or heating apparatus on any premises shall, in the opinion of the inspector, endanger the premises, the inspector shall at once notify, in writing, the owner or agent of said premises. If such owner or agent fails for a period of 48 hours after the service of said notice upon him to make such chimney, flue, or heating apparatus safe, he shall be liable to a fine of not less than $20 nor more than $50 for every day's continuance thereof, to be paid into the treasury of said city.

77. Every smoke pipe in a building entering a chimney flue shall be at least 12 inches from every wooden floor, ceiling, or partition; shall be guarded by a soapstone ring not less than 4 inches in thickness, extending through the partition, or by a double metal collar, with an air space of not less than 4 inches around the same when running through any stud or wooden partition; and no smoke pipe shall project through any external wall or window.

78. The smoke pipe of every furnace shall be kept at least one foot distant from all beams and ceilings not protected by a shield of tin plate at least two inches distant from said beams or ceiling; and no smoke pipe shall be placed nearer than 12 inches to any beam or ceiling, unless the beam and ceiling are plastered, in which case the pipe may be kept within 6 inches of the plastering, if protected by the above described shield; and the top of all heating furnaces set in brick shall be covered with brick, supported by iron bars, and so constructed as to be perfectly tight; said covering to be in addition to and not less than 6 inches from the ordinary covering of the hot air chamber.

79. No furnace and no range set in masonry shall hereafter be placed or its location changed in any building, except as the inspector shall approve.

80. The top of every heating furnace not set in brick shall be kept at least 6 inches below the beams or ceiling, with a shield of tin plate made tight, suspended not less than 2 inches below the said beams or ceiling, and extending one foot beyond the top of the furnace on all sides. If the ceiling over a furnace is plastered, the top of the brickwork may be kept within 6 inches of the ceiling.

81. All hot air register boxes hereafter placed in the floors or partitions of buildings shall be set in soapstone borders not less than 2 inches wide, firmly set in plaster of paris or gauged mortar, or such other protection as shall, in the judgment of the inspector, be equivalent to soapstone; shall be made of tin plate, with a flange on the top to fit the groove in the soapstone, and shall have an open space of one inch on all sides, extending from the under side of the ceiling, below the register, to the soapstone in the floor or partition; the outside of said space covered with a casing of tin plate, tight on all sides, and extending from the under side of the aforesaid ceiling up to and turn under the said soapstone; register boxes of 15 by 25 inches or more shall have a space of 2 inches.

82. No woodwork shall hereafter be placed nearer than one inch to any tin or other metal pipe, to be used to convey heated air or steam in any building, unless protected in a manner satisfactory to the inspector, and such woodwork shall be protected by a soapstone or earthen ring or tube, or a metal casing.

83. Every building in which a steam boiler of ten or more horse-power is placed, shall have the space on the floor allotted for said boiler inclosed in incombustible material satisfactory to the inspector, and shall be so arranged that all openings between the said boiler-room and the other parts of the building in which it is placed shall be protected by iron or metal covered doors, which shall be securely closed at the close of each day.

As AN illustration of the growing substitution of iron and steel for wood, it is stated that in France there have recently come into use hollow iron window frames and doors. It is claimed that they combine the advantages of lightness and strength with great durability.

A NOVEL HOT-WATER HEATING SYSTEM.

THE accompanying illustration shows the general arrangement of a novel hot-water heating plant, designed by W. F. Porter & Co., of Minneapolis, Minn., and installed at the residence of F. L. Brooks, of that city. It need be explained only that a closed tank is used in this system. The main supply pipe, marked M, leads up from the boiler directly to the expansion tank E, and from this the supply pipes to the various parts of the house branch out, descending to the radiators on the different floors. Each radiator has only one valve, placed on the inlet, and when these valves are closed circulation of the water goes on uninterrupted through the pipe system alone. When the valves on any of the radiators are opened, however, circulation through the radiators is established. In the illustration, S represents the safety valve, F a float in the expansion tank to work the water-supply valve, and R an indirect radiator.

The apparatus, as put into Mr. Brooks' residence, is said to perform satisfactorily in all respects. The expansion tank is made of 12-inch pipe, capped, and all the piping measures 1 or 1¼ inch, except the main supply pipe M, which is 3 inches in diameter. All the pipes in the attic are covered with hair felt; the remainder are exposed. The fittings are common cast-iron tees and ells, the valves used being angle valves laid horizontally. For the direct radiation, "Union" radiators, made by the H. B. Smith Company, of New York, are used. About 468 square feet of radiating surface are used, and are divided up as follows: for the first floor in the proportion of 1 to 30, and in the second, in the proportion of 1 to 40. The indirect radiator R is a "Climax" radiator, made by the A. A. Griffing Iron Company, of Jersey City.

A Page steam boiler is used, having a 21-inch fire pot, and a steam dome, though Messrs. Porter & Co. state that in their later practice they substitute for the dome a number of sections. The reason for leaving the dome on was that the plant was put in to be run as a steam job, while the house finish was being placed in position. The advantages claimed for the system are that no air valves are necessary, and no openings are required to be left open to waste water. Messrs. Porter & Co. further claim a positive circulation with an even dirtribution; absence of opportunity for air pockets to form and impede circulation, and ease of filling and emptying the apparatus.

THE ROSE POLYTECHNIC INSTITUTE.

THE eighth annual catalogue of the Rose Polytechnic Institute, of Terre Haute, Ind., has just been issued Like all other publications of this class it gives brief reviews of the courses of study in the different departments, and sets forth the facilities which the institution possesses for instruction in its lines. The course of instruction includes the principles and practice of engineering with special reference to the branches of mechanical and civil engineering, chemistry, physics, electricity and drawing.

Novelties.

Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

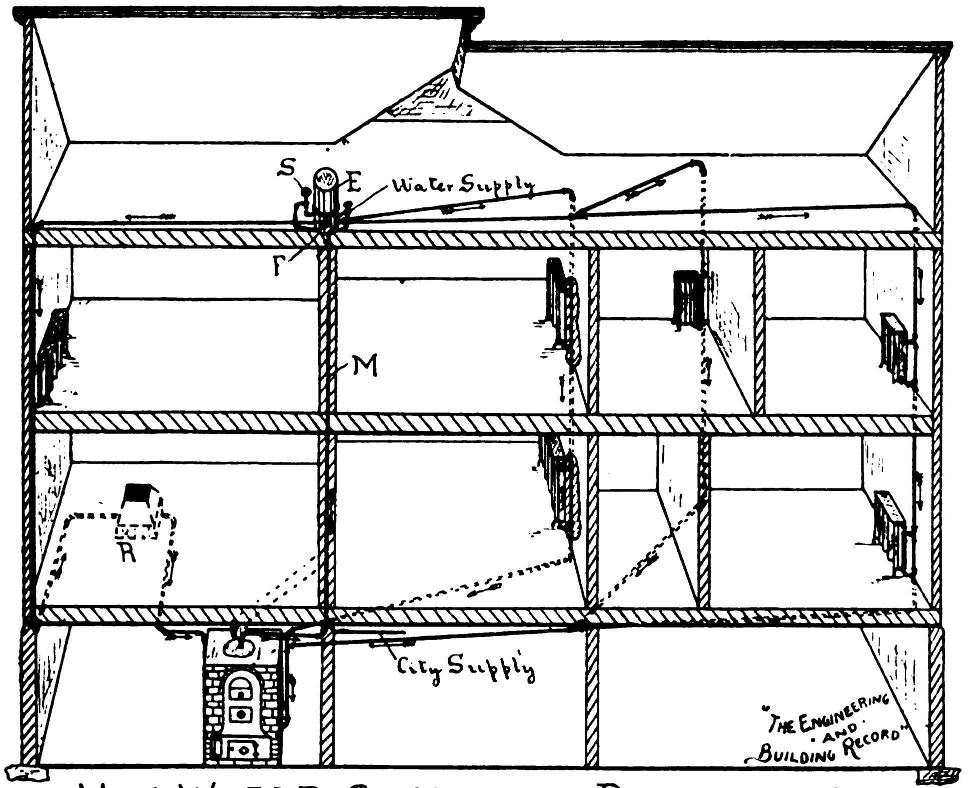
As the subjects are selected for their supposed novelty and interest merely, it will, of course, be understood that the selection does not imply endorsement.

ELECTRICAL SIGNALING APPARATUS FOR GAS EXHAUSTERS AND GOVERNORS.

IT is a matter of frequent observation in gas-works that the governing arrangements of the exhausters are liable at times to be neglected unless under constant supervision; and as a result considerable loss and inconvenience are caused. To obviate this, an apparatus, embodying an ingenious application of electricity to checking the governing and exhausting arrangements of gas-works, has been devised and put in operation at the works of R. Dempster, at Penmaenmawr, North Wales. The *Journal of Gas Lighting* refers to it as follows: It is fixed in such a manner that, when the pressure or vacuum varies from the regulation standard, a bell is set ringing; thus bringing the matter directly before the notice of the engineer or manager.

The apparatus may be described as follows: A small boxwood case, with glass front, is fitted against the wall of the exhauster house. In this box are placed two gauge tubes of about 2 inches in diameter. These are connected at the bottom like an ordinary pressure gauge. A glass bell is made to float in the tube exposed to the atmosphere; the other tube being connected with the gas. The float rises or falls in proportion to the change in pressure or vacuum, and is suspended to the end of a balance lever, the other end having an adjustable screw weight for regulating its position. This lever is pointed with platinum, and is connected to three cells, between which a switch turns the current on or off at pleasure. When the instrument is brought into action, the lever moves in position, and the platinum-pointed end is brought into contact with a platinum-pointed adjustable screw at either side—one representing pressure and the other vacuum. These screws can be adjusted to give warning of alterations of pressure varying from $\frac{1}{10}$ of an inch to any degree required. It will be at once seen that immediately the end of the lever is brought into contact with either of these screws, an electrical circuit is formed, causing one or more bells to be rung. These bells may be placed in a convenient position in the works or offices, and will continue ringing until the pressure or vacuum is adjusted.

It is suggested that there are many other purposes on gas-works to which the invention could be applied with advantage; such, for instance, as giving notice of undue pressure on the station governors, etc.



HOT WATER SYSTEM IN RESIDENCE AT MINNEAPOLIS, MINN.

RUBBER PACKING RINGS FOR GAS-PIPE JOINTS.

AT a recent meeting of the *Mittelrheinischer Gasindustrieverein*, in Germany, particulars were given by Mr. Kugler, of Offenbach, of the substitution of rubber packing rings for the commonly used lead filling in making gas-pipe joints, with pipes ranging from about 3 to 4 inches in diameter. According to Mr. Kugler, the rubber packing had at first been used in connection with pipes having the ordinary bells as employed for lead joints, but more recently pipes with special bells had been tried, the bells having grooves into which the rubber rings fitted accurately. With these modified bells even better results were obtained than in the earlier experiments, entire absence of leakage and eminent durability being claimed for the packing. To protect the rubber rings from destructive external influences a coat of cement is plastered over the outside of the joints.

It was noted that rubber packing for gas pipe joints was used in some localities a number of years ago, but experience with them was not encouraging, possibly on account of a poor quality of rubber being used, and insufficient protection against external corroding agents.

THE LIGHTING OF PARIS.

AT a recent meeting of the International Society of Electricians at Paris M. Fontaine, the President, read an interesting paper on the "Lighting of Paris." He made a comparison of the amount of light used in the years 1855, 1872, 1877, 1883, and 1889 and gave the approximate figures for each source of light, such as candles, paraffin lamps, gas, compressed oil gas, and electricity. On the whole, paraffin oil is the most used at present, gas remains stationary, and electricity is rapidly growing in favor.

Compressed gas has only recently been adopted. Electric lighting commenced in 1877, during which year 230 horse-power was in use; the horse-power in 1883 was 900, and in 1889, 17,400. During 1889 there were 322 installations driven by steam engines, 97 by gas engines, 77 by compressed air, and 22 by vacuum. In addition to the 17,400 horse-power actually in work there are installations representing 10,500 horse-power in course of construction.

COST OF ELECTRIC LIGHT FROM GAS ENGINES.

EXPERIMENTS made by O. Tirrill, 39 Dey Street, New York City, in using a gas engine for electric lighting purposes are said to have shown economical working, notwithstanding the double transformation of energy gone through. The gasoline gas, or rather vapor, was produced by Mr. Tirrill, according to the available data, at $1 per 1,000 cubic feet. The engine was found to consume about 4 cubic feet of this gas per 16 candle-power lamp per hour when driving the dynamo under full load, making the cost per light two-fifths of a cent per hour.

ANNUAL REPORTS.

REPORT ON THE WORKS EXECUTED BY THE COMMISSIONERS OF SEWERS OF THE CITY OF LONDON, during the year 1889.

This report, prepared by William Haywood, engineer and surveyor to the Commission, was issued a short time ago. While embracing only 51 pages it treats of a variety of subjects of interest to municipal engineers, and is, on the whole, more comprehensive than its title would seem to indicate. Besides sewers and house drainage, carriage and footway pavements street lighting, by both gas and electricity, street cleaning and water supply, are among the subjects considered.

SELECTIONS FROM NATIONAL EXHIBITION OF ARCHITECTURAL DRAWINGS AND SKETCHES.

THIS is the title of a handsomely printed quarto publication which contains, as its title implies, a selection of the exhibits at the architectural exhibition held in Cincinnati in November, 1889, under the auspices of the Cincinnati Architectural Club at the time of the annual convention of the American Institute of Architects.

It is a creditable collection and well worth the price charged. It can be obtained of A. O. Elznar, 220 Main Street, Cincinnati, O., for $1, postage paid.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

TRADE PUBLICATIONS.

James Brand, importer of English and German Portland cements, 81 and 83 Fulton Street, New York, has just issued in pamphlet form a paper on "Portland Cement for Engineering Works," prepared by Captain W. W. Maclay, C. E. The paper gives, as Mr. Brand explains, the latest facts on and experiments with Portland cement, designed for the benefit of architects and engineers. In an appendix to the paper are given abstracts of the new German rules for testing cements, and of the system of testing recommended by the Cement Testing Committee of the American Society of Civil Engineers. Directions also are given for using Portland cement and mixing Portland cement mortar and concrete. Mr. Brand will send the pamphlet gratuitously on application.

We have received from the New York Central Iron Works, of Geneva, N. Y., a little pamphlet illustrating and describing the various types of the Duning boiler manufactured by them.

CONTRACTING INTELLIGENCE.

For works for which proposals are requested see also the "Proposal Columns," pages i-31.

PUBLIC IMPROVEMENTS IN NOVA SCOTIA.

Town Office,
New Glasgow, N. S., June 11, 1890.

The Engineering and Building Record:

This town is putting down about 2,000 feet extension to their water system, which, when completed, will make a total mileage of seven miles.

Proposals are about being asked for a system of sewerage and an additional pump.

Blast furnaces are about being erected, and they ask for a supply of 26,000,000 gallons of water annually to supply their works.

This will increase the duty of the engines 50 per cent. over last year. At present we have one of "Blake's Duplex Pumps," capable of delivering 700,000 gallons daily, and they are now working to their fullest capacity supplying the town, the Nova Scotia Steel Works, and the Intercolonial Railway. The town of Stellarton, two miles distant, is negotiating for a supply from our works.

Our system is pumping through system, overflow going to reservoir.

Yours truly, A. M. Fraser,
Town Clerk.

WATER.

For Additional Water Items see Proposal Columns.

Homestead, Pa.—The officials of this place have issued the following circular for the information of water-works construction companies, engineers, water-works supply companies and others interested: "The Borough of Homestead on the 18th day of February, 1890, voted an increase of $70,000 indebtedness for the purpose of building and operating a water-works system, said plant to be owned and operated by the Borough. The needs of Homestead in the way of a water-works plant are from six to eight miles of pipeage, engine, pumps and reservoir, sufficient to supply the present and probable population with water for private consumption and fire protection. The water supply must be drawn either from the Monongahela River, or from artesian wells. The construction of the works will be begun in the spring of 1891 and completed by the fall of the same year. The construction of the plant is in the hands of a committee of five, appointed by the Borough Council, to which committee the Burgess, Solicitor and Clerk have been added as ex-officio members. Preliminary steps are now being taken, and parties interested may address the undersigned, M. P. Schooley, Secretary Water-Works Committee."

Macon, Ga.—Considerable apprehension is felt by some of the city officials regarding the scarcity of water, and active efforts are being made to prevent waste. Mr. Cox, Chairman of the City Council, is in favor of establishing a new system of water-works, to be owned by the city, and suggests issuing bonds in the sum of $100,000 for that purpose. Other officials think that when the waste is stopped the supply will be sufficient. The question is to be considered at an early date.

Calgary, Can.—The people of this place have decided to expend the sum of $60,000 in establishing a system of water-works.

Carthage, O.—The Water-Works Trustees have contracted with the Bradford Well Company to dig a test well.

Lebanon, O,—The citizens of this village want water-works, but as yet no decided action has been taken.

Pottstown, Pa.—It is understood that the contract awarded to Max Tyson, of Reading, for the new water basin, has been declared off and is therefore open again.

Gainesville, Ga.—This place has voted the sum of $40,000 in bonds for the purpose of establishing a system of water-works. The work is to proceed at once.

New Utrecht, N. Y.—The New Utrecht Water Company has been incorporated at this place. Its objects are to accommodate, store, conduit, sell, furnish and supply water for mining, domestic, manufacturing, municipal and agricultural purposes. For particulars, address James A. Townsend, of Bay Ridge, N. Y.

Livermore, Cal.—John Aylward, Superintendent of the Livermore Spring Water Company, writes: "The proposed water-works extension is 2½ miles of 6-inch pipe from the Livermore Springs to reservoirs close to the town, with a pumping station at those springs, and the completion of a large reservoir."

Goffston, N. H.—Regarding the project of water-works at this place, the City Clerk writes: "Surveys have been made and the water analyzed. There will probably be nothing more done this season. Kendrick Kendall, Chairman of the Board of Fire Wards, can furnish particulars."

Statesville, N. C.—Mayor D. A. Miller, writes: "We have submitted the matter of water-works to the people and voters of the town, which will take place on July 7. We have submitted matter on the rental system with the option to buy in five or ten years. We will need five to six miles of mains and pipe, from 45 to 50 hydrants. If ratified by the voters will be ready immediately for contracts."

Blacksburg, S. C.—City Clerk W. B. Anthony, writes: "The City Council has granted the Blacksburg Land and Improvement Company the privilege of establishing water-works, electric lights and a street railway in this city, and they will be the proper parties to contract with for the work, as the Council has given that company the privilege. Work will be commenced at an early date."

East Chattanooga, Tenn.—This place is to have a system of water-works. Address S. Thompson for details.

Florence, S. C.—Information regarding water-works construction is wanted at this place by J. P. Chase.

Boulder, Col.—A new water-works system is to be established at this place.

Tallapoosa, Ga.—The Tallapoosa Water Company will establish a plant at this place. Address for particulars J. M. Crane.

Ashland, Ky.—A water-works system is to be established at this place by the Ashland Water Supply Company,

Monrovia, Cal.—City Clerk O. E. Slosson writes: "The sum of $40,000 bonds have been voted to purchase water, water-bearing lands and develop and conduct same."

Cattaraugus, N. Y.—A water-works system is to be established at this place by the Cattaraugus Water Company. Estimated cost, $25,000. Address, for details, Jessie B. Conway, Secretary.

Spring Valley, Cal.—The Spring Valley Water Company intends constructing immediately a large reservoir. The establishment of several pumping stations, to supply the reservoir, is also to begin soon.

Philadelphia, Pa.—The movement to supply Germantown and other suburbs is about to be realized, and work will be commenced at an early day. Chief Engineer Ogden can furnish particulars.

Ellicottville, N. Y.—A water-works plant is to be established at this place by the Ellicottville Water Company, at an estimated cost of $10,000. Address for details C. P. Vedder, as above.

Hermosa, S. Dak.—City Clerk W. C. Ritchie writes regarding the water-works project as follows: "The City Council had a conference with George W. Chadwick about six weeks ago and they had about come to a satisfactory conclusion to grant a franchise for 20 years, when shortly after Mr. Chadwick died in Rapid City, S. Dak. This put a quietus on the proceedings and nothing has since been done in the matter."

Laurens, N. Y.—The Town Clerk at this place writes: "W. L. Hopkins, W. H. Widger, and Dr. P. K. Strong of this place are interested in forming a water-works here and are meeting with fair success."

Woodstown, N. J.—W. D. Clayton, Borough Clerk, writes: "As yet no definite steps have been taken about water-works plant. Two or three parties have given estimates for supplying the borough with fire hydrants by the year. If suitable terms can be made this most likely will be the plan adopted by our Council. Our townspeople are in favor of having a water supply."

Carthage, Ill.—About 4,000 additional feet of water mains will be laid at this place, and proposals will soon be wanted. Address George W. Payne, City Engineer, as above.

Nicholasville, Ky.—Town Clerk E. R. Sparks, writes: "We are now building a reservoir, and if we are able to get water supply we will build water-works here. Will be glad to have any information on the subject."

Marysville, O.—Town Clerk L. G. English writes: "Ordinance has been passed, contracting with Messrs. Fullington, Zwerner, Davis & McPeck, a home company, to put in a water-works system of a 7-mile plant. Election will be held on Monday, June 23, for the purpose of ratifying contract by the electors. It will, undoubtedly, be adopted, and work will begin immediately upon construction of works."

Oceanside, Cal.—The Oceanside Water Company is being formed at this place, to develop a supply of water for irrigation purposes. The reservoir site of the company is located about five miles from Oceanside, and is of sufficient capacity to store water to irrigate about 10,000 acres of land, and elevation sufficient to reach the highest mesas. The capital stock has not yet been fixed, but it is estimated that $200,000 will be abundant funds to complete the system, which will be about $20 per acre for the lands irrigated. They also contemplate putting water in Oceanside and Carlsbad.

Los Angeles, Cal.—Reports say that efforts are being made to consolidate all the water companies in this city, and that several purchases have already been made with this end in view. J. F. Crank, it is said, has bought the East Side Water Company's plant and also a controlling interest in the plant of the Citizens' Water Company. It is asserted that the City Company will buy out all the companies in the city and consolidate into one system, and that Mr. Crank is now East, floating bonds to raise money to extend and improve the consolidated system as soon as the combine is made.

Long Island City, N. Y.—The Board of Aldermen of this city proposes to appropriate the sum of $6,000 to sinking additional wells for the purpose of increasing the water supply, which is said to have become inadequate. Alderman Desmond can furnish particulars.

Water-Works.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Denver, Col.; Binghamton, N. Y.; Cedar Rapids, Iowa; Jersey City, N. J.; Trenton, N. J.; Rochester, N. Y.; Columbus, O.; East Liverpool, O.; Providence, R. I.; Ottawa, Ont.; Brooklyn Village, O.; Fargo, Dak.; Toronto, Ont.; Geneseo, N. Y.; Providence, R. I.; St. Paul, Minn.; Montreal, Can.

Medina, N. Y.—Bassett Brothers, of Buffalo, N. Y., will construct a complete system of water-works at this place in a short time.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

Scranton, Pa.—Additional sewers have been authorized by the City Council. The City Engineer can furnish particulars.

Cincinnati, O.—Clifton, a suburb of Cincinnati, wants sewerage connection with the latter city. Isaac M. Jordan and Mayor Bowler, of Clifton, are interested in the matter.

Akron, O.—Sewer extensions are to be established at this place. Address the City Engineer.

Middlesborough, Ky.—Colonel Waring is making plans for the sewerage of Middlesborough, which presents features of peculiar difficulty. The town is about 3½ miles long, is practically level, with no point of outlet sufficiently low to obviate the necessity for pumping, and with quicksand of bad character about ten feet below the surface. Contracts have not yet been let.

Mobile, Ala.—Colonel Waring has been engaged by the City Council to visit this city and advise as to the arrangement of a plan of sewerage.

Boston, Mass.—At a recent meeting of the City Council the City Engineer was authorized to at once begin the construction of a brick conduit from Squantum to Moon Island, in place of the present wooden flume connected with the main drainage system, and authorized to spend the sum of $100,000 for the purpose.

Flushing, N. Y.—The officials have authorized the construction of numerous new sewers. Address Judge Clinton B. Smith, Village Clerk.

Ishpeming, Mich.—This town has voted to bond itself to build new sewers.

Ashtabula, O.—Colonel Waring has been employed by this city to advise concerning a system of sewerage.

Marion, O.—It is reported that the people of this place have decided to establish a system of sewers. The City Clerk is B. F. Davis.

Crookston, Minn.—A complete system of sewers is to be established at this place. Address A. R. Starkey, civil engineer, St. Paul, Minn.

Butler, Penn.—A plan for the sewerage of this place has just been completed by Col. George E. Waring, Jr., of Newport, R. I.

Chicopee Falls, Mass.—The contract for the construction of the new sewers at this place has been awarded to C. B. Cadwell, of New Britain, Conn., at 90 cents per linear foot, and $48 each for manholes.

Menominee, Mich., and Iron Mountain, Mich., have employed Mr. Rudolph Hering, C. E., of New York, to report upon sewerage plans now being prepared. It is proposed to build a number of sewers this season. City Clerks for each town can give particulars.

Beverly, Mass.—E. W. Bowditch, C. E., of Boston, has been employed to prepare plans for a sewerage system.

Lakeside, Minn.—The contract for the sewer system at this place and Lester Park has been awarded to H. E. Stevens, of Duluth, for $26,500.

Albany, Ore.—City Recorder N. J. Henton writes: "The city contemplates putting in a complete system of sewerage in 1891. Nothing will be done in the matter until after the Legislature meets, which will be in January, 1891, at which session the right will be granted the city to issue bonds."

Hornellsville, N. Y.—City Clerk H. C. Sawyer writes: "The bill authorizing the construction of sewers in our city has been signed by the Governor. It is necessary that the question now be submitted to the taxpayers as to whether we have them or not. We will have a special election early in July to decide the matter. If decided in the affirmative, the city will issue bonds to the amount of $100,000."

La Salle, Ills.—About $15,000 will be spent on sewer construction this summer—as voted on by Council. Wm. P. Rounds is the engineer.

Piqua, O.—H. C. Babbit, civil and sanitary engineer, of Columbus, O., has been invited to consult with the officials of this place as to a proposed plan for sewerage of the latter city.

Detroit, Mich.—Several miles of main sewers will be built in Detroit after July 1, some of which may be advertised between now and July 1. Apply to Board of Public Works.

Union, N. J.—The following bids for the construction of about 8,400 feet of main sewers were received by Louis Formon, Town Clerk, June 7: Everson & Liddle, Yonkers, N. Y., $142,521; Holmes & Coogan, 316 York Street, Jersey City, $157,217.50; Henry & McGivney, 360 Webster Avenue, Jersey City, $127,906; Deehan Bros. & Co., 1911 Hamilton Street, Philadelphia, Pa., $188,076.25; M. Brennan, 88 Bright Street, Jersey City, $153,283.30; D. R. Paige & Co., 45 Broadway, New York, $159,395; B. Feeney, Bullsferry Avenue, Union Township, $167,745; Myles Tierney, 271 W 73d Street, New York, $142,775.

Southampton, N. Y.—The *Seaside Times*, of this place, suggests that the citizens take some steps towards establishing a sewerage system. Address Walter R. Burling, the editor, for details.

Knoxville, Tenn.—The surveys for the sewerage system are being made by Messrs. Wright & Wood, of this city. The system will be designed by R. Frank Hartford, C. E., of Chattanooga, Tenn.

New Glasgow, N. S.—This place is to have a system of sewers. For details address A. M. Fraser, Town Clerk.

Brooklyn, N. Y.—Proposals were opened June 1, at the City Works Department, for the construction of the main relief sewer, known as Section 1, from Gowanus Canal, through Butler Street to Fourth Avenue, and through Fourth Avenue to Dean Street; also, for a continuation of the same work, known as Section 2, from Dean Street through Fourth Avenue to Hanson Place, through Hanson Place to Greene Avenue, and through Greene Avenue to Marcy Avenue. The bids were received on the following subdivision. For Section 1. (*a*) 2,000 lineal feet of 180-inch diameter main brick sewer; (*b*) 1,000 lineal feet of iron beam covered main brick sewer; (*c*) 1,000 cubic yards of brickwork for the silt and trap basin; (*d*) 46 tons of wrought-iron beams, straps and bolts for silt and trap basin; (*e*) 35 tons of cast-iron plates and columns for silt and trap basin; (*f*) 435 piles for foundation of silt and trap basin; (*g*) 90,000 feet B. M. for lumber used in and about silt and trap basin; (*h*) 90,000 feet B. M. for lumber used in coffer dam about silt and trap basin; (*i*) 6,500 cubic yards of earth excavation, including removal and replacing of crib work at silt and trap basin; (*j*) 3,000 running feet of 12-inch cement pipe drain under main sewer; (*k*) six manholes complete, inclusive of iron head; (*l*) two street basins complete, inclusive of iron pans. For Section 2: (*a*) 800 lineal feet of 180-inch main sewer tunnel; (*b*) 4,400 lineal feet of 168-inch main sewer tunnel; (*c*) 3,200 lineal feet of 144-inch main sewer tunnel; (*d*) 1,000 lineal feet of 120-inch main sewer tunnel; (*e*) 5,000 lineal feet of 12-inch cement pipe (for drain); (*f*) 18 manholes; (*g*) two street basins.

The bidders on Section 1 were as follows:

John McNamee, (subdivision *a*) $43.50, (*b*) $47.50, (*c*) $10, (*d*) $80, (*e*) $60, (*f*) $5, (*g*) $38, (*h*) $50, (*i*) 70 cents, (*j*) 50 cents, (*k*) $100, (*l*) $100.

Daniel J. Crean, (*a*) $28, (*b*) $34, (*c*) $6, (*d*) $70, (*e*) $60, (*f*) $3, (*g*) $38, (*h*) $38, (*i*) $1, (*j*) $1, (*k*) $55, (*l*) $100.

John H. O'Rourke, (*a*) $67, (*b*) $55, (*c*) $12.50, (*d*) $80, (*e*) $70, (*f*) $10, (*g*) $70, (*h*) $70, (*i*) $1, (*j*) $2, (*k*) $150, (*l*) $200.

Charles Hart, (*a*) $55, (*b*) $50, (*c*) $13, (*d*) $82, (*e*) $70, (*f*) $6, (*g*) $40, (*h*) $47, (*i*) $2, (*j*) $1.10, (*k*) $55, (*l*) $120.

Edward Freel, (*a*) $52.50, (*b*) $49.50 (*c*) $12.50, (*d*) $90, (*e*) $65, (*f*) $75, (*g*) $43, (*h*) $60, (*i*) 95 cents, (*j*) $1, (*k*) $65, (*l*) $150.

The bidders on Section 2 were as follows:

Charles Hart, (*a*) $69, (*b*) $65, (*c*) $50, (*d*) $35, (*e*) $1, (*f*) $800, (*g*) $1.

John H. O'Rourke, (*a*) $69, (*b*) $62, (*c*) $58, (*d*) $54, (*e*) $2.50, (*f*) $1,500, (*g*) $500.

The maximum cost of the entire work is $1,000,000.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

Baltimore, Md.—The County Commissioners on June 4 opened the proposals for the building of the following bridges in Baltimore County as follows:

No. 1, over Gwynn's Falls; span 51 feet between walls, and width between iron 13 feet; the bridge will be at right angles with masonry. No. 2, over Herring Run; span 66 feet between walls, and width between iron 16 feet; angle with masonry, 72 degrees. No. 3, over Stemmer's Run; span 60 feet between walls, and width between iron 13 feet; the angle with abutments is 66 degrees. No. 4, over a stream about 1½ miles east of Phœnix Station; span 50 feet between walls, and width between iron 15 feet; the angle with abutments is 49½ degrees. No. 5, at Mt. Washington, N. C. R. R.; span 35 feet between walls, and width between iron 20 feet, with a sidewalk on one side of six feet clear width; the bridge will be at right angles to the masonry. The bids are given by the numbers below as follows:

Penn Bridge Company, Pittsburg, Pa.—No. 1, per lineal foot, $17.20; No. 2, per lineal foot, $20.10; No. 3, per lineal foot, $18,20; No. 4, per lineal foot, $18.90; No. 5, per lineal foot, $22.24. To deduct 50 cents per foot if they receive the contract for the five bridges.

Pittsburg, Pa., Bridge Company.—No. 1, $852; No. 2, $1,337; No. 3, $1,087; No. 4, $960; No. 5, $701.

Wrought Iron Bridge Company, Canton, O.—No. 1, $731; No. 2, $1,115; No. 3, $810; No. 4, $945; No. 5, $795.

Indiana Bridge Company.—No. 1, per lineal foot, $18.85; No. 2, per lineal foot, $20; No. 3, per lineal foot, $19; No. 4, per lineal foot, $19; No. 5, per lineal foot, $26.

King Iron Bridge Company, Cleveland, Ohio.—No. 1, $909; No. 2, $1,449; No. 3, $1,140; No. 4, $998; No. 5, $879.

Youngstown, O., Bridge Company.—No. 1, per lineal foot, $10.12; No. 2, per lineal foot, $10.12; No. 3, per lineal foot, $10 55; No. 4, per lineal foot, $10.76; No. 5, per lineal foot, $11.36. This bid without lumber.

Mt. Vernon Bridge Company, Ohio.—No. 1, per lineal foot, $17; No. 2, per lineal foot, $21; No. 3, per lineal foot, $20.50; No. 4, per lineal foot, $17; No. 5, per lineal foot, $26.75.

Wallace Iron Works, New Jersey.—No. 1, $853.48; No. 2, $1,271.98; No. 3, $1,157.31; No. 4, $850. No. 5, $882.52.

Berlin Bridge Company, E. Berlin, Connecticut.—No. 1, $1,123; No. 2, $1,410; No. 3, $1,178; No. 4, $1,133; No. 5, $1,014.

Dean & Westbrook, New York.—No. 1, $1,015; No. 2, $1,329; No. 3, $1,240; No. 4, $1,090; No. 5, $1,120.

Columbus, O., Bridge Company.—No. 1, $755.46; No. 2, $959.36, No. 3, $807.30; No. 4, $1,147.30; No. 5, $618.26.

The papers were all referred to Mr. Wm. H. Shipley, the Superintendent of Bridges, to report on the same. The Berlin Bridge Company and the Indiana Bridge Company afterwards withdrew their bids.

Wheeling, W. Va.—Plans are being prepared by the City Engineer for the construction of the bridge at Main Street, this city. The estimated cost is $92,000.

Shelburne, Mass.—Plans and specifications have been completed for an iron bridge to span the Deerfield River, at this place, to be erected at a cost of $18,000.

Rochester, N. Y.—City Surveyor Peacock has completed plans for a bridge to be erected over the river, at Court Street. The structure is to be erected at an estimated cost of $175,000.

Tonawanda, N. Y.—The bill re-appropriating $20,000, and making a further appropriation of $12,000 for an iron bridge over the Tonawanda Creek and Erie Canal at this place, has become a law.

Rochester, N. Y.—City Surveyor O. H. Peacock writes: "The matter of establishing a bridge over the river at Court Street has been referred to the City Surveyors for an ordinance authorizing its construction."

Albany, N. Y.—The Canal Board met June 10, and adopted plans and estimates for lengthening Locks 40, 42, 43 and 46 on the Erie Canal, Locks 8 and 12 on the Oswego Canal, and for partially rebuilding Lock 1 on the Black River Canal. The Board also adopted plans and estimates for placing machinery in the locks to be lengthened on the Erie Canal, for rebuilding a bridge over the Erie Canal, required by the lengthening of Lock 42, and for building a stone culvert at James Street, Rome. The original contract for lengthening Lock 42, Erie Canal, was abandoned.

New Haven, Conn.—Civil Engineer J. E. Budington has submitted plans for a stone bridge at Springside Farm, New Haven, to connect Wintergreen and Springside Avs.

Shrpherdstown, W. Va.—Reports say that a steel bridge is to replace the wooden structure over the Potomac River, which has been damaged by recent floods.

Evansville, Ind.—An iron bridge is to be erected over Pigeon Creek, at Ohio Street, by the County Commissioners.

Huntington, Conn.—It is reported that New Haven and Fairfield Counties will, jointly, build an iron bridge over the Housatonic River, at this place.

Grand Rapids, Mich.—Reports say that a bridge is to be erected over the river at Lyons Street, this city.

Lancaster, Pa.—A bridge is to be erected over the Octoraro River, at Little Britain Township by the Commissioners of Lancaster and Chester Counties.

Logan, Iowa.—Reports say that two iron bridges will be erected over the Snake River, at this place.

Hackensack, N. J.—Iron bridges are to be erected over the Saddle River, at Garfield.

Middletown, N. Y.—The City Engineer has been instructed to prepare specifications for two bridges, to be built here.

Pikeville, Ky.—Regarding the projected bridge over the Big Sandy River, at this place, Town Clerk C. M. Parsons writes: "We have our charter from the Legislature of Kentucky and books open for stock. We hope to be able to begin work soon, yet the work is not yet let to contract. Would be glad to receive bids at any time before letting from contractors."

Cincinnati, O.—East Cumminsville citizens have petitioned the Board of Public Works to build a bridge over Mill Creek for vehicles and pedestrians.

Grand Rapids, Mich.—Our correspondent writes: "The G. R. & I. R. R. Co. has secured plans for a new double-track iron railroad bridge which they will build shortly to replace an old wooden one now in use in this city, spanning Grand River at a point where it is about 500 or 600 feet wide No further particulars are known, except that no estimates have been made as yet."

Minneapolis, Minn.—Bids have been received for the bridge over the railroad tracks at Second Avenue, as follows on the iron superstructure: Milwaukee Bridge Company, $35,370; Canton Wrought Iron Bridge Company, $38,900; Shiffler Bridge Company, Pittsburg, $40,600; Chicago Bridge and Iron Company, $35,518; Keystone Bridge Company, Pittsburg, $43,600; King Bridge Company, Cleveland, $43,000; Wisconsin Bridge Company, Wauwautosa, $39,257; South Bridge Company, Toledo, O., $42,489; Fair, William & Co., Ottumwa, Iowa, $33,900, informal.

There were four bidders on the substructure, as follows: Granite, per cubic yard, $35; Mankato stone, per cubic yard, $11; piling, per lineal foot, $0.26; lumber, per thousand, $20; excavation, per yard, $1.

The bridge will be of iron, will include four spans 506 feet in length, with a roadway of 18 feet, and walks 6 feet wide on either side.

Bids were also opened for the substructure of the new bridge on Fifteenth Avenue southeast, and Ring & Tobin were awarded the contract, their bid of $8 per cubic yard for the masonry, or a total of $8,080. The grading for this bridge, 15,000 cubic yards, was awarded to E. F. Comstock & Co., at 16 cents per cubic yard, or a total of $2,400.

Guttenberg, N. J.—A number of surveyors have been engaged in surveying the bluffs of the Palisades at Guttenberg to secure a landing for the western end of the proposed North River Bridge. The plans are nearly completed.

Paterson, N. J.—Town Clerk William Nelson writes: "A committee has been appointed to confer with a similar committee of the Bergen County board regarding the projected bridge over the Passaic at Thirty-third Street; the latter board has just appointed a committee. The Passaic board has authorized a committee to solicit bids for a new iron bridge across the Passaic River at Little Falls, to take the place of the old covered wooden bridge at that place. It is to be in one span, about 140 feet long."

McKeesport, Pa.—It is probable that the Port View Bridge Company's foot and wagon bridge to span the Youghiogheny River at the foot of Thirteenth Avenue will be built soon. Frederick Wilson, the Secretary of the company, states that the directors will at once arrange to have plans and specifications for the structure prepared.

Duluth, Minn.—Engineer A. P. Boller writes that the plans and specifications for the foundation and masonry for the new bridge across the canal will soon be ready, and that he will arrange for plans to be seen either at his office in New York or at the office of the Board in this city. Plans will be ready and advertised so that bidders will be able to make tenders by the first of July.

Leavenworth, Kan.—There is a project on foot in this city favoring the erection of a viaduct over the Missouri Pacific tracks, the estimated cost of which is $30,000.

Brooklyn, N. Y.—The Park Commissioners opened proposals June 11 and made awards for the erection of a bridge over an arm of the lake in Prospect Park. The foundation is to be of granite and concrete and the superstructure of iron work. The bidders for all the work are as follows: The King Iron Bridge and Manufacturing Company, $53,758; Harris & McGuire, $54,797; L. E. Brown, agent, $55,700; Poulson & Eger, $60,693; John J. Hopper, $52,925. For the iron work separately there were bids as follows: Wallis Iron Works, $15,542; Poulson & Eger, $18,100; Post & McCord, $18,580. There were separate bids for the stone work as follows: The King Iron Bridge and Manufacturing Company, $36,758; L. E. Brown, $37,100. The Commissioners awarded the contract for the iron work to the Wallis Iron Company, of Jersey City, at $15,542, and the contract for the stone work to L. E. Brown, builder, Brooklyn, N. Y., at $37,100.

Sioux City, Iowa.—Reports say that a pontoon bridge is to be erected over the Missouri River at this place, by the Pacific Short Line.

Augusta, Ga.—A bridge is proposed over the canal at Broad Street.

Front Royal, Va.—Reports say that the Front Royal and Riverton Improvement Company will build one or more iron bridges.

Houston, Tex.—It is proposed to connect the Second and Fifth Wards by a bridge.

Buncombe County, N. C.—It is said that two bridges are to be placed over the French Broad River and one over Cave Creek in this county. The Board of Magistrates can furnish details.

Bridges.—See our Proposal Columns for information regarding bridge construction at the following places: Pembina, N. Dak.; Eureka, Cal., Alder Point, Cal.; Mitchell, Dak.; Lynchburg, Va.; Boston, Mass.; Duluth, Minn; Evansville, Ind.

NEW DEPOTS.

Pittsburg, Pa.—New freight depots and round houses will be erected and other improvements, to cost $400,000, will be made in this city by the Baltimore and Ohio Railroad Company.

STREET-WORK AND PAVING.

Akron, O.—Considerable brick paving will be done this summer. For further information address City Engineer, Akron, O.

Grand Rapids, Mich.—Our correspondent writes: "Grand Rapids is likely to profit in the near future from the present agitation concerning new paving. Some action affecting several thousand feet of streets will very likely be taken shortly."

Montreal, Can.—Reports say that the City Council has decided to borrow $10,000,000, to be devoted to harbor improvements and permanent road works.

St. Paul, Minn.—The Arlington Hills Citizens' Union will petition the Council to open Payne Avenue for travel from Joy Street to White Bear road, and to pave and curb Bradley Street from Seventh to Decatur, out Decatur to Payne and along the latter street to Jessamine.

Scranton, Pa.—Numerous streets are to be paved. Address the City Engineer for details.

Amsterdam, N. Y.—All the proposals for the paving of Market Street, recently opened, have been rejected as being excessive. New bids will soon be wanted. Address Clerk of the Common Council for particulars.

PHILADELPHIA, PA.—The Sub-Committee on Improved Pavements, of Councils' Highway Committee, has decided upon the distribution of the $180,000 appropriated out of the permanent loan for repaving with improved pavements streets not occupied by passenger railways.

BIRMINGHAM, ALA.—The contract for paving Main Street, this place, has been awarded to C. W. Blakeslee & Sons, of New Haven. The figure was not made public.

LEAVENWORTH, KAN. — A boulevard is proposed for this city. Address Col. C. S. Chase, as above for particulars.

RAILROADS, CANALS, ETC.

NEW PHILADELPHIA, O.—The Pennsylvania Railroad Company has decided to extend the Tuscarawas branch, beginning at Bayard, on to Dennison.

GAS AND ELECTRIC-LIGHTING.

PITTSFIELD, MASS.—Reports say that the directors of the Pittsfield Gas Company have contracted with the United States Gas Improvement Company, of Philadelphia, Pa., for a water-gas plant, to cost $30,000.

MEMPHIS, TENN.—The Voltaic Electric Manufacturing and Supply Company has been incorporated here, with a capital stock of $1,000,000. Incorporators: J. W. Allison, R. M. Stratton and others.

JOHNSTOWN, N. Y.—The Board of Trustees has closed a contract with the Johnstown Power Company to light this village for a term of two years with 2,000 candle-power arc lights at $75 per light per year, the company to furnish 50 lamps or more if needed.

ELSWORTH, ME.—The electric light plant at this place has changed hands, and is to undergo extensive improvements.

PENN YAN, N. Y.—The contract for public lighting has been awarded by the Board of Trustees to Messrs. C. and H. Russell, at $3.300 per annum for 45 arc lights to burn all night.

FAIRMONT, W. VA.—This place is to have electric lights.

CHICAGO, ILL.—The Worrall Electric Construction Company has been incorporated here with a capital stock of $500,000, to construct and maintain electric plants. Incorporators, C. E. Gaylord, M. J. Frost and others.

KITTANNING, PA.—This place is to have electric lights.

TOLEDO, O.—The Toledo Electric Light Company is to enlarge its plant.

OMAHA, NEB.—An electric lighting plant is to be established at this place.

ELIZABETH, PA.—A plant is to be established at this place by the Elizabeth Electric Light, Heat and Power Company. Proposed outlay, $10,000.

SCRANTON, PA.—The South Side Electric Light, Heat and Power Company has been incorporated at this place, with a cash capital of $12,000.

PASO ROBLES, CAL.—The Central Milling Company, of this place, will put in an electric light plant in connection with its new flouring mill, and will light the city.

DAYTON, ORE.—The electric light plant at this place, which was recently destroyed by fire, is to be re-established.

TECUMSEH, MICH.—The Tecumseh Electric Light Company has been incorporated at this place. Capital, $30,000.

LOUISVILLE, KY.—Efforts are being made to establish an electric light plant at this place.

GARDEN CITY, ILL.—An electric lighting plant is to be established at this place by the Garden City Electric Lighting and Power Company. Estimated cost, $25,000. Address Charles A. Buell, as above.

DETROIT, MICH. — The United Electric Company has been incorporated at this place with a cash capital of $50,000.

KALAMAZOO, MICH.—This city will have 4,000 more incandescent lights.

IRON MOUNTAIN, MICH.—The Iron Mountain Electric Light and Power Company has been incorporated at this place, with a capital stock of $25,000.

CEDARTOWN, GA.—This place is to have electric lights.

ST. PAUL, MINN.—Additional gas mains will be laid here.

BAR HARBOR, ME.—Improvements and extensions are to be made to the plant of the Bar Harbor Illuminating Company.

MORRISTOWN, N. J.—The plant of the local electric light company is to be improved.

SACRAMENTO, CAL.—The Sacramento Electric Construction Company has been incorporated at this place, with a cash capital of $1,000,000. W. Gambs can furnish information.

COPENHAGEN, CAN.—An electric lighting plant, to have a capacity of 10,000 incandescent lamps, is to be established at this place.

LOS ANGELES, CAL.—An electric lighting plant is to be established at this place by the Rhodes & Keese Electric Company. The proposed expenditure is $25,000. For particulars, address Col. G. Wiley Wells, as above.

CINCINNATI, O.—The directors of the Zoological Garden have decided to put in an electric light plant of 500 incandescent lamps.

ELECTRIC RAILWAYS.—New electric railways will be established, and improvements will be made to those already built. at the following places: Boston, Mass.; Quincy. Mass.; Cincinnati, O.; Sioux City, Iowa.

BIDS OPENED.

MINNEAPOLIS, MINN.—Court House.—The Board of Commissioners of Morrison County has let the contract for the erection of a court house at Little Falls to Foster & Smith, of Minneapolis, at $43,974. There were fourteen bidders, ranging from $42,588 to $59,300.

GOVERNMENT WORK.

WASHINGTON, D. C.—The following proposals for the construction, etc., of new naval vessels were opened June 10 by the Secretary of the Navy: For the 8,100-ton ship, the Union Iron Works of San Francisco, $3,100,000 on the plans of the department, or $3,000,000 on the bidders' plans; the William Cramps & Sons' Shipbuilding Company of Philadelphia, $3,150,000 on department's plans, $2,985,000 on the bidder's plans; the Risdon Iron and Locomotive Works of San Francisco, $3,450,000 on the department's plans.

One bidder put in an estimate on the 5,500-ton vessel, the Union Iron Works of San Francisco, whose bid was $1,796,000 on the plans of the department, or $1,760,000 on their own plans.

For the practice vessel two bids were received: F. W. Wheeler & Co., West Bay City, Mich., $245,000; the Samuel L. Moore and Sons Company of Elizabethport, N. J., $250,000. No awards were made.

PITTSBURG, PA.—Synopsis of bids for iron furring, lathing and plastering the U. S. Court House, etc., at this place, opened by the Supervising Architect of the Treasury Department:

PORT TOWNSEND, WASH.—Synopsis of bids for stone and brick masonry for the superstructure of the United States Custom House, etc., at this place, opened by the Supervising Architect of the Treasury Department: C. P. Wakeman & Co., $93,754.62; Jos. Summers, $99,720; Ritter, Harlin & Mattill, $72,500.

INDUSTRIAL.

CUMBERLAND GAP, TENN.—The East Cumberland Gap Land Company is reported to have employed Col. George E. Waring, Jr., Newport, R. I., and Messrs. Wright & Wood, of Knoxville, Tenn., to plan and lay out a new town near this place.

Mr. William B. Bigelow, architect, No. 52 Broadway, is making plans for a hotel to accommodate 500 guests.

Mr. John Dufais, No. 337 Fourth Avenue, is making plans for a casino, to cost $5,000, and a sanitarium, with a capacity for 100 patients. A topographical survey of the ground is now being made by Waring, Chapman & Farquhar, under whose direction the work of construction will be prosecuted. No bids have yet been let.

MIDDLESBOROUGH, KY.—The Harrogate Land Company, owning about 700 acres, is laying out, under the direction of Colonel Waring, an ornamental village, as a residence for the business men and manufacturers of Middlesborough. The work of laying out and grading streets, water supply, sewerage, etc., will be under the direction of Waring, Chapman & Farquhar.

GREENSBOROUGH, N. C.—The North Carolina Steel and Iron Company of this place are laying out a manufacturing town with an area of 2,000 acres, with streets, walks, business, manufacturing and residence sites. George E. Waring, Jr., has been employed as consulting engineer.

WANTED.

TOO LATE FOR CLASSIFICATION.

WANTED—AN ARCHITECTURAL Draughtsman, competent to take charge of office work. Only those wishing to make long engagement need apply. If contract is made, traveling expenses will be paid. J. W. STEVENS, Architect, St. Paul, Minn.

PROPOSALS.

(Continued from page i.)

Notice to Water-Works Tunnel Contractors.

SEALED PROPOSALS WILL BE RECEIVED at this office until FRIDAY, June 20, 1890, at 10:30 o'clock A. M., for furnishing all materials and doing all the work necessary and required to construct a **WATER-WORKS TUNNEL** seven and one-half (7½) feet in diameter out three thousand (3,000) feet under Lake Michigan, including two (2) shafts, wells and crib, according to plans and specifications on file in this office.

Bidders will submit their bids in accordance with the terms of the specifications.

Work to be completed on or before the 1st day of June, 1891, failing in which the contractor shall pay to the city of Milwaukee, as liquidated damages, the sum of $700 per day for each and every day's delay in completing the contract.

Bonds to accompany bids required in the penal sum of $40,000, signed by two sureties, or in lieu thereof the bidder may deposit with the Board of Public Works the sum of $20,000 in money or certified check.

Sureties must be residents of this city.

All bids must be stated in writing and figures.

All moneys deposited will be returned to unsuccessful bidders on award of contract, and to successful bidders when contract is entered into.

Before the award of the contract the Board of Public Works must be satisfied of the ability and facilities of the successful bidders to perform the work according to the terms of the specifications and this advertisement.

The Board of Public Works reserves the right to reject any or all bids.

Dated MILWAUKEE, June 3, 1890.

G. H. BENZENBERG,
G. DUNCK.
W P. O'CONNOR,
G. P. TRAEUMES,
Commissioners of Public Works.

Countersigned:
FRED. F. WILDE,
Deputy Comptroller.
2

To Contractors.

SEALED PROPOSALS WILL BE RECEIVED by the Board of Public Works in and for the corporation of the CITY OF DULUTH, MINNESOTA, at their office in said city up to July 1st, 1890, for constructing the **PIERS AND FOUNDATIONS** of a draw bridge over the Ship Canal across Minnesota Point, Duluth. Plans and specifications may be seen at the office of said Board, on and after June 15, where form of contract and of tender may also be obtained.

Plans, specifications, and forms may also be seen at the office of Alfred P. Boller, Consulting Engineer, 71 Broadway, New York.

Bids will be received only from contractors who are experienced in the class of work called for, and the Board reserves the right to reject any or all proposals.

MYRON BUNNELL,
Pres. Board of Public Works.
Official: GEO. T. HUGHES, Clerk.
3

PROPOSALS.

PROPOSALS FOR WATER-WORKS.

SEALED PROPOSALS ADDRESSED TO the City Clerk will be received by the city of GALESBURG, ILL., until 5 o'clock P. M., July 1, 1890, for furnishing materials and labor, and doing the work required to build a system of **WATER-WORKS** in and for said city. Proposals will be received for the whole or the separate portions of the work, and the plans and specifications may be seen at the office of the City Clerk or at the office of the Engineer in Chicago after June 24th.

Accompanying each proposal must be a certified check payable to the city of Galesberg, Ill., or its equivalent, for $500.00, as a guarantee that the bidder will enter into and execute the contract awarded him and which deposit will be forfeited if he fails so to do.

The right is reserved to reject any or all bids.
By order of the City Council.

JOHN. C. STEVENS,
City Clerk.

CHESTER B. DAVIS, Engineer,
549 Rookery Building, Chicago, Ill.

Notice to Contractors.

SEALED PROPOSALS WILL BE RECEIVED by the Board of Directors of the North Hudson Driving Park Association, at their office, No. 113 Hudson Street, HOBOKEN, N. J., until 7.30 P. M., June 19, for **GRADING** the infield of the Guttenberg Race Track at North Bergen, N J. Plans and specifications can be seen, and all information obtained at the office of Messrs. BEYER & McCANN, Civil Engineers and Architects, Hudson Place, Hoboken.

N s St Marks av, 120 e Rogers av, 3 br dwells; cost, $19,500 all; o, H L Chappell and others; a, G P Chappell.

S s Jefferson av, 6 br dwells, cost, $24,000 all; o and a, S J Burrows.

E s B'way, 27 n Vanderveer st, 2 br dwells; cost, $30,000 all; o, W E Cozzens; a, W M Coots.

N e cor Vandeveer av and Broadway, br dwell; cost, $30,000; o, W E Cozzens; a, W M Coots.

N s Broadway, 22 e Cooper av, 2 br dwells; cost, $22,000 all; o, J A Soucks; a, W M Coots.

N e cor Broadway and Cooper av, br dwell; cost, $18,000; o and a, same as above.

S s Macon st, 22 w Ralph av, 10 br dwells; cost, $53,000 all; o, R F Clayton; a, W F Clayton.

S s First st, 100 w 7th av, 4 br dwells; cost, $20,000 all; o, J Kalle; a, R Dixon.

N s St Marks av, 100 e Nostrand av, br dwell; cost, $20,000; o, J Hills; a, G P Chappell.

S s Jefferson av, 95 e Stuyvesant, 4 br dwells; cost, $19,600 all; o, Lambert & Mason; a, I D Reynolds & Sons.

N s 50th st, 120 w 4th av, 3 fr dwells; cost, $7,200; o and a, A Svenlin.

N s Jefferson av, 95 w Stuyvesant, 4 br dwells; cost, $24,000 all; o, W C Bush; a, J E Dwyer.

MILWAUKEE, WIS.— Cor 1st av and Washington st, church; cost, $10,000; o, Southside Baptist Congregation; a, J Douglass; b, Geo Czaplewski.

Michigan and Milwaukee sts, alteration of theatre; cost, $14,000; o, George, Boyd & Lewis; a, W A Holbrook; b, Ellis & Coogan.

Bids will be advertised for in a few days for work on a new $400,000 hotel. H C Koch, architect.

The Hanover St Congregational Church will erect a new building. Address Rev Theo Clifton, as above.

MINNEAPOLIS, MINN.—738–48 E 18th st, 3-story br ten; cost $30,000; o, a and b, A Berg.

1113–15 Washington av, N, br store and ten; cost, $12,000; o, K Goldblum; a, F A Clarke; b, Carl Peterson.

700–04 Marshall st, N E, fr stores and flats; cost, $15,000; o, Frank Shepard; a, Mr Barber; b, Reau & Brude.

1412 Yale pl, fr dwell; cost, $10,000; o, James A Paige; a, Geo M Goodwin; b, A J Sampson.

SIOUX CITY, IOWA.—N w cor Douglas and 13th sts, row of br houses; cost, $45,000; o, Joseph Sampson; a, not let.

4th st, cor Jennings, 5-story office bldg; o, James Rockwell; a, G G Baldwin.

Pearl st, cor 9th st, St Mary's Catholic Church; cost, $40,000; b, Jas P Wall.

Pearl st, cor 16th st, fr res; cost, $18,000; o, R J Chase.

Douglas st, fr res; cost, $21,000; o, R C A Flournoy; a, C P Brown.

Central Park, summer house; cost, $7,000; o, John Pierce; a, same as above.

3-story livery stable; cost, $25,000; o, Geo Westcott; a, G G Baldwin; b, C K Poor.

Flouring mill; cost, $28,000; o, G Y Brown.

An English syndicate will build a beef and pork packing house on the Floyd, to cost $100,000. Walter Strange is their representative, a, Joseph Nicholson, Chicago.

The Union Stock Yards Company will build an exclusive beef packing house, to cost $75,000, to be operated by parties from Nebraska City; a, same as above.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D.C.

VOLUME 22.
NUMBER 3.
PUBLISHED EVERY SATURDAY.
277 PEARL ST., NEW YORK.

NEW YORK, JUNE 21, 1890.
LONDON, JULY 5, 1890.

SINGLE COPIES, TEN CENTS.
Subscription, $4.00 per year in advance, post paid. IN AMERICA.
SINGLE COPIES SIXPENCE.
Subscription, 20*s*. per annum in advance, post paid. IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.

20*s*. in GREAT BRITAIN. Other Foreign Countries $5.
Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & CO., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $5; China, Japan, Sandwich Islands, Mexico and Cuba, $5; South America, $5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

THE SUBWAY PROBLEM IN NEW YORK.

THE serious gas-pipe explosion at the corner of Broadway and Fulton Street, New York, last week, followed within a few days by two underground steam pipe explosions near the same point, has evidently done much to re-awaken a lively public interest in the much-discussed subway question. These latest accidents, while perhaps not much more serious than a large number of others of the same class which have occurred within the past year, have been accompanied by a greater show of outward destruction, and have proved correspondingly more effective in rousing public indignation and clamor for relief.

The conclusion reached in some quarters several years ago, and staunchly upheld by THE ENGINEERING AND BUILDING RECORD, as reference to back volumes will show, that a system of substantial subways to accommodate steam, gas, and water pipes, pneumatic tubes, electric cables, etc., and to provide for sewage disposal, offers the only satisfactory solution of the problem of successfully managing so elaborate a network of underground conduits as is found in a great city like New York, would seem at last to have become generally established, and it ought now require but little additional agitation to have at least preliminary work commenced on a rational subway system. The necessarily heavy expense involved in the construction of one main subway or tunnel for all underground pipes and wires, and the temporary inconvenience which would be entailed by it, have always been more or less effectively urged against the prosecution of such an undertaking. The fact has, however, apparently been lost sight of that in the near future the city would actually be driven to it, and that the lapse of time would only add to the difficulties, dangers and expense of the work.

The present outrageous condition of New York streets and underground work is the natural result of short-sighted policy to which THE ENGINEERING AND BUILDING RECORD has again and again directed attention. Street upheavals menacing the safety of life and property, entailing traffic disturbances of the most serious kind, and an ever present promise that matters would constantly grow worse, have all been of little or no avail in shaping the course of the New York City government so far as this branch of the Public Works Department is concerned. As matters now stand, however, a climax seems near at hand. The latest accident has conclusively shown that the dangers of explosion from defective underground work have, in part, been transferred from the streets to the buildings bordering them, and it is a matter of unpleasant speculation how long it will be before a calamity of yet unrecorded proportions will be added to the already long list of minor street accidents.

The authorities of Paris long since appreciated the necessity of placing their gas and water pipes and electric wires in subways, and their method of utilizing sewers for such a purpose, as illustrated on another page in this issue, will be found suggestive, though for the conditions existing in New York the plan proposed in Col. Julius Adams' report, published in our issue of August 4, 1888, and commented on in the issue of October 6, 1888, is more in the line of what will ultimately have to be carried out in New York. As we have frequently stated no time should be lost in taking steps to restrict each industry to one set of pipes in the lower part of the city—and in the matter of gas insisting that they shall have thoroughly sound mains and services—which, under present conditions, it seems impossible to secure or at least maintain.

ABOLITION OF HORSE CARS IN NEW YORK.

THE Court of Appeals of New York State have rendered a decision that permits any street railway company in the State to change its motive power from horses to cables or electricity by obtaining consent of half the property owners along its route, and without the consent of the local authorities.

This confirms the constitutionality of the act of 1889, which provides that any street railway company which has obtained the consent of half the property owners may apply to the State Railroad Commissioners for permission to change its motive power The constitutionality of the act was questioned because it did not include consent of the local authorities as one of the requirements for the change, but the Court decides that such consent is necessary only in the granting of new franchises.

It is announced that the largest two corporations are ready to begin the change to cable traction at once—namely, the Third Avenue road and the Broadway line. The change from horses even to cable traction will, unquestionably, prove a great boon to the citizens of New York.

On the other hand, it is to be regretted that electric propulsion on the storage battery system has not received more favorable consideration. In the light of recent experience this system has shown itself to be, beyond all doubt, the ideal one for street car propulsion, and what has been accomplished with it on the Fourth Avenue line at New York has not unreasonably suggested the possibility of its general application in crowded cities. Underground work in the streets and the consequent tearing up of pavements would be entirely uncalled for by it, a point which alone should favorably commend it. The important matter of cost of operation and maintenance is the only one, we believe, which has been considered as likely to present difficulties, and even this would seem to have been satisfactorily disposed of in the practical tests at New York. It would seem, therefore, that the Railroad Commission should look carefully into this matter before consenting to cable roads in the lower part of the city.

STREET CLEANING IN THE CITY OF LONDON.

WILLIAM HAYWARD, engineer and surveyor to the Commissioners of Sewers of that portion of London, England, known as the "city," in his recently issued report for the year 1889, gives some interesting particulars on the cleaning of the streets within the jurisdiction of the Commissioners.

Briefly summed up, the system, as carried out, involves daily sweeping of the carriage ways, while the main thoroughfares in wet weather are frequently swept twice a day. Besides this, the street orderly system is carried out on all the main, as well as in some of the important secondary, thoroughfares. Altogether about 150 boys and young men are employed for this purpose during the working days of the week. The advantages of this street orderly system are, as might be expected, most apparent in wet weather. The work of cleaning the main thoroughfares often begins at 2 or 3 o'clock in the morning, and is, in nearly all cases, finished by 8 or 9 A. M. The street orderlies commence their work at 7.30 A. M., after the streets have been swept, and cease work at 4.30 P. M.

In addition to this almost continuous cleaning by hand some of the carriageway pavements, when the weather permits or necessity requires it, are washed with jet and hose. The courts and alleys inhabited by the poorer classes are not only cleaned daily, but are also usually washed with jet and hose twice a week between May and the end of October. A few places are, for special reasons, washed nightly throughout the year.

The sidewalks are swept by the Commission whenever it is found necessary, and in wet weather those in the main thoroughfares are cleaned with squillgees during the day.

With so comprehensive a system of street cleaning a good condition of the streets, as regards cleanliness, may reasonably be looked for, and is, no doubt, secured. The street orderly system, in many places, has much to commend it, and might, to great advantage, be given a wider range of application.

BENEVOLENT WORK BY THE INSTITUTION OF CIVIL ENGINEERS.

A NOTABLE instance of work of the incidental kind by an engineering association is given by the report cf Benevolent Fund of the Institution of Civil Engineers in England. The fund was established in 1864, and is managed by a committee of six elected for the purpose, with the President of the institution as chairman *ex officio*. The purpose of the fund is to give assistance to meritorious members of the institution and their families, to the families of deceased members, to persons who have been members five consecutive years and to their families.

The income is from investments of money belonging to the fund and from annual subscriptions. By the annual report for 1889, which has just come to hand, it appears that the amount set apart as permanent capital in 1865 was £22,833, which had increased at the end of 1887 to £25,659. Lord Armstrong proposed in 1888 to add £5,000 to the capital, on condition that other members of the institution contributed a like sum, and the £10,000 addition to the capital made in this way is to be known as the Lord Armstrong Fund. The receipts from annual subscriptions and dividends in 1889 amounted to £2,981, and the grants to £3,070. The capital is now put at £37,506. It would be a graceful act for some one of the pecuniarily successful members of the American Society of Civil Engineers to start a fund for a similar purpose in the United States.

THE BROADWAY CABLE ROAD.

THE Broadway and Seventh Avenue Railroad, of New York City, has applied to the State Railroad Commissioners for permission to substitute cables for horses as motive power. Their plan calls for a duplicate cable system from Central Park to South Ferry, by way of Seventh Avenue, Broadway, Battery Place, and Whitehall and State Streets. The conduit is to be a tube of steel with a ⅝-inch slot at the surface. It will be 2 feet 6 inches deep, and 1 foot 6 inches wide. The conduit will be surrounded by a bed of concrete 6 inches thick. Every 4½ feet there will be an iron frame, or yoke, further supporting the concrete and the rails. Side-bearing rails will be used, and the space between and outside of the rails will be paved with granite blocks resting upon the concrete and iron frames. Every 31½ feet there will be pulley pits, each containing two pulleys for the two cables. The conduits in the two tracks are connected with a manhole between the tracks. A sewer pipe will drain the conduit.

The shafts of the pulleys are to be suppored by bearings having self-oiling attachments, and the rims of the pulleys are to be lined with a composition metal, so as to diminish the noise of the cables. Both slot and track rails are to be of steel, the slot rails to weigh 65 pounds to the yard and the track rails 82 pounds to the yard.

The cable system is stated to be substantially the same as that now in use in Pittsburg and that now being put in in Baltimore and West Chicago, except that this system has two cables and is heavier and stronger in construction. Each cable and its supporting pulleys are entirely independent of the other and its supporting pulleys, so that both cables can be in operation or at rest at the same time, or one in operation and the other at rest. The machinery is so arranged that the cars can be easily and quickly transferred from one cable to the other, and the grips of the cars are made double, so as to take hold of either of the cables as occasion requires.

It is proposed to have an electric signal service for speedily stopping or starting the cables. An insulated wire will run either between the tracks or along the conduits, having signal boxes at short intervals under manhole covers.

ENGINEERING AND ARCHITECTURAL DEGREES CONFERRED.

AT the commencement of the Rensselaer Polytechnic Institute this week the degree of Civil Engineer was conferred upon the following named graduates:

Carl Frederick Adam, Buffalo; William Henry Arnold, Troy; Lawrence Parker Butler, Jefferson Barracks, Mo.; William Dinsmore Card, Pittsburg, Pa.; William Easby, Jr., Media, Pa.; Walter George Filer, Sharon, Pa.; Antonio de Barros Franco, S. Paulo, United States of Brazil; Richard David Gottlieb, Chicago; Bertrand Eugene Grant, Troy; Charles Kirschner, Troy; Antonio Llano, Medellin, Republic of Columbia; Arthur Bernard Mader, Cincinnati; Liberty Gilbert Montony, Troy; Winfield Scott Potter, Brooklyn, N. Y.; Willett George Ranney, Cleveland, O.; K. Oake P. Reinholdt, New Castle, Pa.; Percival Mosley Sax, Nashville, Tenn.; James Wilson Shields, Mt. Pleasant, Pa.; Ogle Tayloe, Warren, Troy.

Cornell University conferred degrees as follows:

Bachelor of Science in Architecture.—Charles Hay Bernheisel, Frank Horton Brown, Clement Benjamin Brun, George Willard Conable, Clarence Ephraim Dobbin, Alexander C. Eschweiler, Edward Thomas Fallows, Arthur Norman Gibb, William T. Sherman Hoyt, Edwin Henry Hulbert, Edwin Augustus May, Floyd Lucien Robinson, Charles Goodwin Sands, Frederick Farley Sewall, George Francis Seymour, William Adam Stevens, Herman Frederick Stuhr, Alexander B. Trowbridge, Henry Wilhelm Wilkinson.

Civil Engineer.—Nelson Seymour Crouch, Joseph Haines Dickinson, Franklin Marcus G. Dood, Albert Edward Duckham, William Jackson, B. S., Herbert Henry Landers, Gustav Frederick Roess, John Franklin Skinner, Clinton Brown Stewart, Bunzo Sugi, William Twining, Thomas McEldeny Vickers, Joel Edward Wadsworth, Robert Bruce Wilcox, Frederick Kelley Wing.

Mechanical Engineer.—Louis Lees Bentley, Ernest Spencer Bowen, P. M. Chamberlain, B. S., Fred Andrew Crossman, William Dalton, Francis Daniel Davis, John Jackson Ewing, Elbert Curtiss Fisher, Ferd Guy Gasche, Victor Ignatius Hahn, Benjamin Marvin Harris, Charles Louis Heisler, William R. Webster, Jr., George Cleveland Hicks, Jr., Wilson Freeman Higgins, Embury Asbury Hitchcock, Edwin Curtis Knapp, Charles Philip Miller, William Stanton Monroe, William Dye Mount, Harry Trevenen Shick, Louis Lincoln Smith, Henry King Spencer, Ernest August Stege, Guy Harold Thayer, Daniel Upton.

Master of Civil Engineering—Ernest Martin Holbrook, C. E.

Master of Mechanical Engineering.—George Ira Alden, B. S.; Arthur Bernard Levy, B. S.; William Wilb. Churchhill, M. E.; Louis Benedict Marks, B. S.; John Joseph Flather, P. B.; Arthur Tannatt Woods.

Mechanical Engineer in Electrical Engineering.—George Hall Ashley, Henry Primm Broughton, Percy Alfred Clisdell, Hayward Cochrane, Joseph Walker Cowles, Samuel B. Fortenbaugh, Frank Fairfield Goodwin, John Eckert Greenawalt, Louis Watres Healy, Arthur Hobart Herschel, Sherwood Johnson Larned, Max Levy, Julius Smith Loomis, Ph. Bell Woodworth, B. S., William Henry Powell, Joseph Cowan Ramage, Eugene Aertsin Rumsey, Harland Aaron Sawyer, Eugene Charles Sickles, William Nelson Smith, Olin Ames Stranahan, Milton E. Thompson, Howard Ford Thurber, William Boardman Tobey, George Hicks Walbridge, Edward H. Waldo, A. B., John Ackroyd West, Jr., Ed. Adam Wilheim.

The Stevens Institute of Technology conferred the degree of Mechanical Engineer upon graduates as follows:

Alberto Atristain, N. F. Lawrence, A. H. Hill, H. M. Brinckerhoff, J. F. Haworth, Shirk Boyer, William N. Carlton, John D. Dehart, Jr., Charles J. Everett, Jr., William Ebsen, E. W. Frazer, William M. Farrar, Eugene E. Hinkle, Sol Fechheimer, Carl Graf, A. R. Whitney, Jr., D. C. Harvey, Harry P. Jones, W. W. Kissam, S. F. Smith, Henry S. Loud, G. A. Trube, G. W. Merritt, Ernest H. Peabody, Louis R. Mendoza, J. T. Westcott, A. B. Moore, Frank Moynan, Alfred Nathan, Walter F. Phelps, Leonard D. Wildman, Francis B. Stevens, Jr., Hugh Wreaks, R. S. Twitchell, Frederick Thuman, George L. Todd, Henry Torrance, Jr., C. W. Trautvetter and E. H. Whitlock.

THE Bowen-Merrill Company, Indianapolis, will publish shortly a useful work for lawyers interested in highway and railroad cases, entitled, "The Law of Roads and Streets," by Byron K. and William F. Elliot. The book will treat of the general principles of the law of roads and streets. It does not deal with statutes, except in an incidental way, but discusses the general rules of law.

ANNUAL CONVENTION OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS.

IT is announced that at the annual convention of the American Society of Civil Engineers, at Cresson, Pa., next week, the President's Address will probably be made Thursday evening. Thursday, Friday, Saturday and Monday will be occupied partly by meetings and partly by excursions by rail to points not far from Cresson, probably including Altoona, Johnstown (Cambria Iron Works) and Bell's Gap. The banquet will be, as now arranged, on Saturday evening. The convention will probably close Monday evening or some time Tuesday, but doubtless many will stay at Cresson several days longer.

The special train leaves Pennsylvania Railroad ferry, foot of Cortlandt or Desbrosses Street, New York City, Wednesday morning, June 25, at 10 o'clock.

A PRESS dispatch says that oil has been discovered along the banks of the Mercer County, O., reservoir, and that two syndicates have been formed to lease the entire tract and bore for oil under the water. The reservoir covers 16,000 acres, and one of the syndicates has offered an annual rent of $48,000 for a ten years' lease. The reservoir is the main feeder of the Miami and Erie Canal, and the only obstacle in the way of perfecting the lease is the fear that the water will become contaminated from the waste oil. It is claimed that a plan to prevent this has been devised, and the syndicate offers to enter into bonds to keep the waste oil out of the water. It is urged that the rent offered would put the entire canal in good condition and make it a strong competitor of the railroads in the carrying trade from Lake Erie to the Ohio River.

OBITUARY.

CAPT. C. M. CLARKE, C. E., of Washington, D. C., is reported to have committed suicide June 14, from mental aberration caused by overwork in the sun.

PERSONAL.

HARRY J. MARCH, of the class of 1887, has been given the honorary degree of Civil Engineer by Rutgers College.

EMORY C. DAVIS, of Northampton, Mass., has been appointed Engineer of the projected improvements in the water-works of Springfield, Mass.

E. L. ACTON, architect, Dayton, O., has moved his office from the Hollencamp Block to the new Newsalt Block, corner of Fourth and Jefferson Streets.

J. F. LEBARON, recently in charge of work on the Nicaragua Canal, has opened an office at 61 Broadway, New York City, as civil and consulting engineer.

THOMAS C. CLARKE has been appointed Chief Consulting Engineer, and William B. Brush Assistant Engineer of the "Greene" Hudson River Bridge Company.

J. J. DEKINDER, C. E., of Philadelphia, Pa., has been invited by the Board of Improvements of Cincinnati, O., to take charge of the city water-works for three months.

JAMES C. BAYLES, of East Orange, N. J., ex-President of the New York City Board of Health, has been given the honorary degree of Doctor of Philosophy by Rutgers College.

CARL W. BUCHOLZ, M. Am. Soc. C. E., has been appointed by President Howell, of the Brooklyn Bridge Company, one of the Board of Experts to examine and report in regard to terminal facilities for the bridge.

GEN. SAMUEL B. HOLABIRD, Quartermaster General U. S. Army, who has served with distinction since his graduation at West Point in that important branch of the service, has been retired, having reached the age of 64. His successor has not yet been appointed.

COMING MEETINGS.

THE annual convention of the American Society of Civil Engineers will open at Cresson, Pa., at 10 o'clock Thursday morning, June 26.

ENGINEERING SOCIETIES.

THE ENGINEERS' CLUB OF PHILADELPHIA held a meeting June 7, with Vice-President Wilfred Lewis in the chair; Howard Murphy, Secretary. There were 15 members present and one visitor, William P. Shinn, President of the American Society of Civil Engineers.

The Secretary presented, for Strickland L. Kneass, a description of a New Condensing and Refrigerating System.

THE BOSTON SOCIETY OF CIVIL ENGINEERS had an excursion to Worcester, Mass., June 17, by invitation of Charles A. Allen, City Engineer of that city. There were about 65 members of the Society in the party. Incidentally the party inspected the Cochituate dam now being constructed at Natick, Mass., and also the filtering beds, or sewage farm, connected with the Framingham sewage works. From there the party was conveyed by barges to South Framingham where the train was taken for Worcester, at which place it was received by City Engineer Charles A. Allen and Superintendent of Sewers Richard Forbes. After dining the visitors were conveyed to the new sewage disposal works at Worcester. These works are not yet in operation, so that a good opportunity was furnished to inspect their construction in detail. This system, a description of which appeared in this journal May 10, involves chemical precipitation, the chemicals being mixed in wooden tanks which discharge their contents into the open conduit or raceway through which the sewage flows from the gatehouse on its way to the precipitation tanks. From there, after chemical action has taken place, the sewage finally passes through the effluent channel into the river. For the present it is the intention to pump the sludge into the sludge well, whence it is carried by conduit across the river and discharged in the open ground, where it may be plowed in or possibly pressed into cakes and burned. It is expected to have the system in operation in about two weeks.

After inspecting the works and listening to an explanation of its features the party returned to Boston, having thoroughly enjoyed the trip.

The society held a regular meeting June 18, with Vice-President J. R. Freeman in the chair, S. E. Tinkham, Secretary, and about 55 members and visitors present.

Francis Blake, of Weston, Mass., Frank P. Johnson, of Waltham, Mass., George H. Nye, of New Bedford, Mass., and George C. Stoddard, of Newport, R. I., were elected members. Edward P. Fiske, of Boston, was elected an associate member.

A paper by Hiram F. Mills, C. E., was presented, entitled, "Purification of Sewage by Filtration and by Chemical Precipitation," referring to experiments made in the last few years by the Massachusetts State Board of Health, of which Mr. Mills is a member.*

A short account of the construction of the new sewerage system at Worcester was also given by the City Engineer, Charles A. Allen. Wilbur F. Learned, Assistant Engineer Boston Water-Works, read a paper on the "Chemical Treatment of Sewerage at Winchester, Mass."

Discussion followed each paper, various members participating.

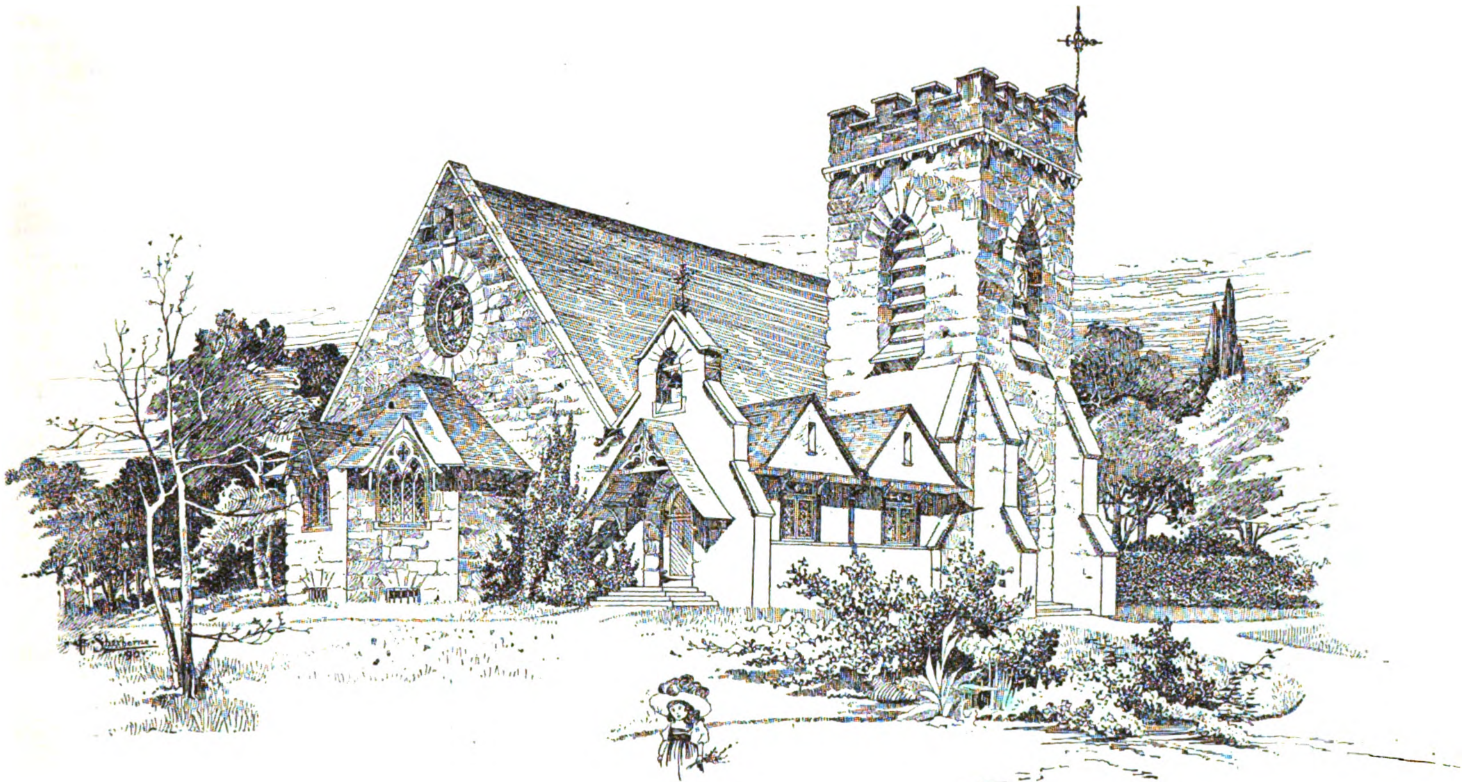
THE ENGINEERING ASSOCIATION OF THE SOUTHWEST held a meeting at Nashville, Tenn., June 12, President John MacLeod, of Louisville, Ky., in the chair, O. H. Landredth, secretary, and 32 members present.

Chairman MacLeod from the Committee on "Affiliation with the American Society," reported that it had been impossible for any member of the Committee to attend the meeting of the Committee of the American Society at New York, June 4, and asked the discharge of the Committee, which was granted. The subject of joining the Association of Engineering Societies was discussed and correspondence with the officers of the Board of Managers of that organization was submitted. The decision was referred to the Executive Committee of the Board, with power to act.

John B. Atkinson, of Earlington, Ky., presented a paper on "Coke Making in the Western Kentucky Coal Field." It dealt very extensively with a series of trials and experiments carried on at Earlington, Ky., to solve for that district the question of desulphurizing coke, which is made from slack coal only, carrying a higher percentage of sulphur than the coarser grades of coal. The author found the condition and character of the coal and the manner of the occurrence of the sulphur in the coal so different from that found elsewhere that no parallel could be drawn from outside experience. This was verified by repeating at Earlington, in succession and without avail, the methods which elsewhere were successful. Mr. Atkinson's work to date is only partially successful, but it is still being prosecuted, and it is hoped that it will be of the greatest commercial importance to the Western Kentucky coal belt, whose product is at present not available for iron making.

THE AMERICAN SOCIETY OF CIVIL ENGINEERS held a regular meeting June 18, with Vice-President A. Fteley in the chair.

The secretary announced the completion of arrangements for the Cresson convention, and that the attendance was expected to be very large, over 70 gentlemen and 30 ladies having arranged to go on the special train from New York, June 25. Several papers, in addition to those announced, have been presented for this meeting and the sessions. An adjournment was followed by the usual collation.



TRINITY CHAPEL, CHESTNUT HILL, PA.—LINDLEY JOHNSON, ARCHITECT, PHILADELPHIA, PA.

WATER-WORKS IMPROVEMENT AT SPRINGFIELD, MASS.

CLEMENS HERSHEL and Alphonse Fteley have made a report in regard to the projected improvement in the water supply of Springfield, Mass., substantially endorsing the scheme submitted by C. M. Slocum, the City Engineer, in 1889, and it is hoped that work will soon be proceeded with.

WATER was let into the New Croton Aqueduct for the first time in a regular way Tuesday. The purpose was to flush it out and test the working of the gates, etc., and a stream about 18 inches deep was allowed to flow about 20 miles to South Yonkers, where it was discharged through the blow-off there. The test was under the immediate management of Messrs. Rice, Gowan and Craven, engineers on the aqueduct, and was satisfactory.

THE New Jersey Court of Errors has sustained the decision of a lower tribunal refusing to permanently enjoin the city of Passaic from discharging its sewage into the Passaic River. The injunction was asked for by Newark, as the discharge tends to contaminate its present water supply, as well as that of Jersey City.

---

*This paper will be noticed at length in a future issue.—EDITOR.

NEW ENGLAND WATER-WORKS ASSOCIATION CONVENTION.

(From our Staff Correspondent.)

PORTLAND, ME., June 12.

AT Wednesday's session, reported in part last week, a paper by Joseph C. Hancock, Springfield, Mass., was presented, entitled "Effect of Water Hammer in Large Pipes, and How Remedied." When water running through a pipe or inclosed conduit is suddenly checked the result is a concussion or shock, the same as when any moving solid is suddenly stopped. This concussion or shock, in the case of water, is commonly called water hammer. To a greater or less degree it may be avoided by closing gradually the passage through which the water is running. When the stopping of the flow of water in a main or large conduit is not so regulated the result is often the rupture of the conducting pipe or the starting of joints, the effect being nearly parallel to that of suddenly stopping a moving train, as in a collision. Just as by the application of the brake the train is gradually stopped without any injurious effect, so the shock of water hammer can generally be avoided by taking care to shut the gate slowly, closing by degrees the passage through which the water is flowing.

In the discussion which followed, W. H. Richards, of New London, Conn., recommended that a relief valve be placed at the point where the water hammer is first felt as at the gate.

Mr. Stacey, of Marlboro, Mass., thought that water hammer depended on the length of pipe and the velocity of the water flowing through it.

J. M. Clark, of Northampton, Mass., gave a brief description of a peculiarly constructed valve with a perforated plunger, partially automatic in its action, by which, in the case of a locomotive supplied from a stand-pipe, the water might be turned off suddenly without any water hammer. Water hammer was produced by the turning off of railroad station stand-pipes, and pipes were frequently ruptured when the supply was directly from the main. It was stated that building a tank to be supplied through a ball cock from the main, the stand-pipe taking its supply from the tank, was the only satisfactory thing to do. With that arrangement there was no trouble from sudden turning off of water.

THURSDAY MORNING SESSION.

The regular morning session was called to order at 10 o'clock, with President Dexter Brackett in the chair, and nominations by the committee being presented, officers for the ensuing year were elected, as follows:

President—Albert F. Noyes, City Engineer, West Newton, Mass.

Vice-Presidents—George P. Wescott, Treasurer Water Company, Portland, Me ; Charles K. Walker, Superintendent, Manchester, N. H.; F. H. Crandall, Superintendent, Burlington, Vt.; P. Kieran, Superintendent, Fall River, Mass.; William B. Sherman, civil engineer, Providence, R. I, and W. H. Richards, Superintendent, New London, Conn.

Secretary—R. C. P. Coggeshall, Superintendent, New Bedford, Mass.

Treasurer—Hiram Nevons, Superintendent, Cambridge, Mass.

Senior Editor—F. H. Parker, Burlington, Vt.

Junior Editor—Albert S. Glover, West Newton, Mass.

Executive Committee—Frank E. Hall, Superintendent, Quincy, Mass.; Dexter Brackett, Superintendent, Eastern Division, Boston; Charles W. Morse, Superintendent, Haverhill, Mass.

Finance Committee—Herbert F. Whittier, Registrar, Lawrence, Mass.; George E. Winslow, Superintendent, Waltham, Mass., and Frank A. Andrews, Assistant Superintendent, Nashua, N H.

Prof. William T. Sedgwick, of the Massachusetts Institute of Technology, gave a discourse on the "Utilization of Surface Waters for Drinking Purposes," drawing largely from a paper by W. H. Lindley, City Engineer of Frankfort-on-the-Main. The standards applied to drinking water are to-day much higher than they were years ago. The purest is spring water, but this does not exist in sufficiently large accumulated quantities to supply large communities, where it is necessary to secure an abundant supply. The first requisite is quantity rather than quality. Wells, cisterns and filter basins are insufficient in any but sparsely settled districts and most communities must eventually come down to river water, whether good or bad. River water is often much contaminated, as the Hudson River, which is so polluted by the cities on its banks emptying their sewage into its waters that Hudson River ice is shown to be very bad. That from the lakes in Massachusetts, even the worst of it, is better than Hudson River ice. There is great desirability of more legal protection from contamination of the sources of water supply, especially mountain lakes. River water may be purified by settling and filtering. By carefully regulated sand filtering it is possible to remove much of the brown color, certain chemical contaminations and a portion of the living germs. An accumulation of "dirt deposit," so called, the formation of a gelatinous membrane, is necessary for the proper action of the filter. Clean sand allows most of the bacteria to pass through, but this is prevented in great measure by the accumulation of this gummy membrane, which, therefore, is essential for the most effectual working of the sand filter. Where there is danger of the formation of ice, as in Russia, the filter should be under cover. The sand filters at Berlin, Germany, are very effectual in changing the polluted river into clear water. River water must be filtered rapidly and just the right kind of sand must be used and the work must be carried on in just the right manner. Yet, in spite of all care and precautions, there is great danger that some of the germs will pass through. Although the most of the color and the algæ may be removed from water by the sand filter we can never be certain that none of the germs have passed through. While the standards of physicians and hygienists are properly high, it should be borne in mind that the hygienist and sanitary engineer should understand each other's requirements. The removal by filtering of most of the foreign matters, including certain living organisms which prey upon them, leave to the bacteria present an undisputed field to multiply even more rapidly than before this purification, and accordingly water should be used as soon as possible after filtering.

In the discussion which followed, Desmond Fitz Gerald, Superintendent of the Western Division of the Boston Water-works, said that these problems were of growing importance. Every town, in considering its water supply, must have, first, quantity, and that too often without much regard to quality. It is remarkable how water purifies itself while running over a broken surface. Filtering is just beginning to have close attention from a scientific standpoint. Certain experiments for the purification of water are now being carried on at Chestnut Hill Reservoir, Boston, but these are only supplementary to those of the State Board of Health. At the Chestnut Hill Reservoir the experiments are being made with both continuous and intermittent filtering side by side to determine their relative value.

James C. Bayles, of East Orange, N. J., thought that filtering was chiefly mechanical. To true oxydation we must look for eliminating many injurious matters in water. Aeration plays an important part in the purification of water. Mr. Bayles gave some particulars of an apparatus for filtering, by which the oxydizing process was accomplished and the resulting water made as pure as possible.

In answer to a question as to the value of aeration, Professor Sedgwick said that it removed certain injurious gases which might be present. It is not yet known definitely just the size of filter necessary to purify a given amount of water per day. This must be determined by experiment.

A paper, entitled "Why I Favor the Use of Cement-Lined Pipe," was next presented by P. F. Crilly, Superintendent, Woburn, Mass. The vital requirements for service pipes are durability and freedom from corrosion. Cement-lined pipe exactly fulfills these conditions. Much of the disfavor in which such pipe is held is due to poor quality and inferior work in laying, through incompetency or dishonesty. Twenty to twenty-five years is the usual life of cast-iron pipe, so that the work of renewing it is constantly going on. Cement-lined pipe has been in use from 20 to 40 years, and the water which had passed through it was as free from rust and discoloration as when delivered to the pipes. In addition to its first cost being greater, cast-iron pipe is made still more expensive on account of the frequent renewals necessary. During the past year there have been only five repairs of all descriptions on the 43 miles of cement-lined pipes at Woburn, and of these repairs only two were of any importance. On the other hand, a case was cited where, after having been laid 13 years, cast-iron pipe was found to be badly corroded.

In discussing the matter Charles K. Walker, of Manchester, N. H., said that the question was, "Can the town take the risk of getting first quality pipe and of having it properly laid?" for unless the work is well done there is sure to be needless trouble and expense. Mr. Walker gave a very amusing account of the experience of a superintendent of a works where cement-lined pipe had been put in. The first year he was an enthusiastic advocate of it, the second year he admitted a few breaks, but meeting him the third year, Mr. Walker said, in his droll way, that he asked him how cement pipe was now, the answer came: "Good God! Charles, I'm nearly druv crazy. I git a complaint of a cellar fillin' up, and I go to shet off, when the wimen say: 'Look a-here, you; this is wash day, an' if you shet off your men hev got ter lug water for my washin'.'" Mr. Walker "brought down the house."

Mr. Allis, of Malden, Mass., said that the life of cast-iron pipe could be placed at 50 years, and it had lasted 100 and even 150 years. Certain soils, however, rapidly corrode cast-iron pipe. Opinions were also expressed by Messrs. Nevons, Dennett, Steben and others, strongly favoring cast iron rather than cement-lined pipes.

THURSDAY AFTERNOON.

At the Thursday afternoon session the convention listened to an address by A. Fteley, of New York, Chief Engineer of the Croton Aqueduct Commission. The most remarkable feature of this work was its magnitude, and the excavation of the tunnel extended through three years and four months, the first shovelful of earth being removed January 1, 1885. The total length of the tunnel is 30¾ miles; that of the aqueduct 33⅛ miles, and even in the dryest time it will yield a supply of 250,000,000 gallons of water per day. In the length of the aqueduct there are three blow-offs or vents, from which the conduit may be emptied. Under Harlem River the depth of the shaft is about 400 feet.

From the head gate house, at Croton Dam, there start in a bunch eight 48-inch mains. This gate-house cost $750,000. From an engineering point of view a very interesting fact was developed in experimenting on the permeability of brickwork by water under pressure, with special reference to preventing loss of water by this means. It was found by experiment that by coating brick with, say, two coats of Portland cement, as a paint, a loss of 100 parts of water was reduced to 1½ parts; an immense saving. Accordingly two miles of the Croton Aqueduct have been coated in this way to prevent loss of water by percolation under pressure. The address was illustrated by large profile drawings and lantern views. In answer to a question, referring to a report that had been current, Mr. Fteley stated that the internal pressure was too great to permit any sewage draining into the aqueduct.

On behalf of the committee appointed, W. H. Richards offered a report recommending that Hartford, Conn., be selected as the place for the next annual convention of the association, and that the secretary be instructed to transmit to the Mayor of Toronto the thanks of the association for his invitation to them to hold their next annual meeting at that place, which was prohibited by a clause of the constitution restricting meetings to places in New England. The recommendations of the report were adopted.

John A. Gould, Jr., Assistant Engineer, Boston, presented a paper on "Recording Gauges," in which the usefulness of these instruments and their various purposes, showing the height of water in stand-pipes, the pressure of water in mains, boiler pressure, etc., were briefly outlined.

A paper on "Water Meters; the Advisability of Their Use," was presented by G. A. Roullier, Superintendent, Flushing, N. Y. To establish uniform and equitable rates and a proper form of inspection of the consumption are two very important duties of those having the management of water-works. The water meter furnishes the most efficient means of meeting these requirements. As showing the great value of the water meter as lessening waste, etc., a few figures were given showing the practical working of the meters at Flushing. In 1886, with a pressure of 75 pounds at the pumps, the pressure at the office was reduced to 35 pounds, and the consumption was 120 gallons per capita. In spite of much opposition 100 meters were set where the greatest waste was supposed to be, and the pressure of 35 pounds was increased to about 42 pounds, the daily consumption per tap falling from 754 to 578 gallons. The system of metering was afterwards extended with so much benefit that the maximum daily consumption per tap for 1889 was the same as the minimum for 1886. There are now 630 meters set, and the coal consumption has been reduced 400 pounds per day.

In the discussion Mr. Fitz Gerald said that he believed in the water meter. In his own town he took the stand, three years ago, that on account of the great waste there should be no extension of the works without the introduction of meters. The system of metering has been adopted, and the present consumption is the same as that of a number of years ago.

W. R. Billings said that simplicity and permanence are the qualities in a meter more valuable than absolute accuracy in measurement.

Mr. Chace, of Taunton, cited an instance where, in the case of a dissatisfied water taker, the meter was taken out and tested, when it was found to under-register about 4 per cent. A meter out of order is generally in favor of the consumer.

With reference to this latter statement Mr. Brackett said that after passing 300,000 to 500,000 cubic feet of water the ⅝-inch meter will generally under-register 4 to 10 per cent., so that after passing this quantity he recommended that the meter be tested.

Further remarks on the subject were made by S. M. Allis, C. K. Walker, and J. W. Ringrose.

Some discussion followed on the different ways of charging for water meters in different places. Mr. Brackett stated that in Boston all the meters are put in and owned by the city, except in the case of very large meters, where rent is charged.

Mr. Hawes believed that the city should own the meters and charge rent for them, and that the consumers should not own them. Mr. Roullier said that it was the custom in Flushing for the consumer to buy the meter. The city, however, takes care of it and replaces it when worn out.

F. L. Fuller and others participated in this discussion.

On motion of Mr. Hawes, it was voted that the thanks of the association be extended to the Mayor of Portland, the city government and the Portland Water Company for courtesies shown by them to the association during its convention.

THURSDAY EVENING SESSION.

Promptly at 8 o'clock the convention was called to order by President Brackett. On recommendation of the Executive Committee it was voted that the status of James C. Bayles, of East Orange, N. J., be changed from associate to that of non-resident active member.

On suggestion of Mr. Allis, the subject of the "Minimum Size of Mains for Fire Supply" was brought up for discussion. Mr. Brackett said that in many cases the pipes in use are too small, and the time will come when the authorities will require larger ones. In the city of Baltimore were laid last year five or six miles of 4-inch pipe. Four-inch mains should not be used in any case for hydrant supply, and 6-inch mains in many instances are used too much in long lengths where a number of hydrants are to be supplied from one main.

Mr. Winslow gave some particulars of experiments conducted by J. R. Freeman to determine the resultant loss of pressure from drawing a number of streams from a 4-inch pipe used as a fire supply at a factory at Waltham. Four streams drawn from this pipe through 2 inch hose with 1-inch nozzles reduced the pressure to 34 pounds, the static pressure being 77 pounds. In the case of 6-inch pipe the pressure was reduced to 34 pounds by eight streams. With the fire pumps eight streams reduced the pressure to 38 pounds. The conclusion was that 4-inch pipes were insufficient, and, while 6-inch pipe would answer the demands in a great measure, larger sizes would be better. In an instance cited, where a 4-inch pipe was used for fire purposes, so great was the drain in the pipe that a faucet, opened at that time in a house near by, actually sucked air in.

Remarks on this subject were made by F. L. Fuller, J. A. Gould, Jr., S. M. Allis and others, and various experiences were given showing the inadequacy of 4-inch pipe for fire protection and recommending 6-inch pipe or larger for this purpose.

Mr. Brackett briefly described the method he had used for cleaning certain 6-inch water pipes in Boston, by which their conducting capacity was increased 300 per cent. Some particulars were given of the construction of the machine used for this purpose, which required a pressure of about 40 pounds to force it through the pipe and remove the obstruction.

Mr. Nevons referred to an unsuccessful attempt made in Cambridge to clean in a similar manner about 1,000 feet of 6-inch pipe. The machine used would not pass through even under a pressure of 45 pounds.

A paper by Joseph C. Hancock was next presented in which the question of the depth of lead necessary in pipe joints was considered. This depth should be 1½ to 2 inches, and not less than 2 inches for safety in high service pipes.

Mr. Winslow spoke of pipe laid in Waltham under contract which, in some cases, had a depth of lead in the joints of not more than half an inch, and as a consequence there had been many leaks in such joints.

Mr. Allis referred to the use of wooden plugs or wedges which he had heard had been used in the place of lead for calking pipe joints. In the discussion Mr. Nevons and others took part.

As a subject demanding serious consideration, Mr. Winslow called attention to the great inequality in the size of hose outlets on hydrants. He found that there were over 200 different sizes in the country. The standard size should be known by water-works superintendents on ordinary hydrants.

Mr. Brackett thought that there should be some standard of size of hose couplings and outlets on hydrants. In the case of the great Boston fire many of the out-of-town fire engines could not be used because their hose couplings would not fit the Boston hydrants. There are different standards of size in different cities, but these standards should be uniform. In the case of hydrants, some open to the left and others to the right. Of the former kind, those in Boston, Charlestown district, are being changed so as to open to the right.

Mr. Fuller thought that the association should take some action looking to the adoption of a uniform standard of size of hose couplings, hose outlets on hydrants and the direction in which the latter open.

At the close of the session a vote of thanks was given to the President, Dexter Brackett, and the Secretary, R. C. P. Coggeshall, and the meeting adjourned.

The following new members were elected, besides those reported last week:

Resident Active Members.—D. N. Clark, President Water Company, Portland, Me.

W. H. Childs, Superintendent Water Company, Manchester, Conn.

C. M. Brainard, Superintendent, Skowhegan, Me.

Theodore H. McKenzie, Superintendent, Southington, Conn.

Non-Resident Active Member.—B. D. McConnell, Superintendent Water-Works, Montreal, P. Q.

Associate Member.—Smith & Anthony Stove Company, Water-Works Supplies, Boston.

The association was complimented by a banquet at the Falmouth Hotel, given by the Portland Water Company, the Mayor and prominent citizens being present. The activity of ex-Mayor George T. Westcott, Manager of the Portland Water Company, in making the meeting pleasant and successful was thoroughly appreciated, which fact was manifested at the banquet.

The total registered attendance at the convention was 125. The list of members and visitors present was as follows:

James Barnie, Superintendent B. and L. Water Company, Biddeford, Me.

Charles H. Baldwin; Albert A. Blossom, Whittier Machine Company; Harold L. Bond, Supplies; Dexter Brackett, Superintendent Eastern Div. Boston Water-Works; Mrs Dexter Brackett; A. B. Daggett; Mrs. A. B. Daggett; F. W. Dean, Mechanical Engineer; C. N. Fairbairn; Frank L. Fuller, civil engineer; Albert S. Glover, Hersey Meter Company; Mrs. Albert S. Glover; W. N. Goddard, King & Goddard; X. H. Goodnough, State Board of Health; J. A. Gould, Jr., Assistant Engineer, City Engineer's Office; E. H. Gowing, Engineer; Wilbur F. Leonard, Assistant Engineer; J. A. Mitsch; Frank Polsey, Walworth Manufacturing Company; Edward H. Rice, Walworth Manufacturing Company; Fred H. Rounds; Daniel Russell, Steam and Hot Water Heating; William T. Sedgwick, Professor of Biology, Mass. Inst. of Technology; Smith & Anthony, Manufacturers; F. E. Stearns, Peet Valve Company; Frederick P. Stearns, Chief Engineer, State Board of Health; Eugene S. Sullivan, Superintendent, Mystic Division; James A. Tilden, Superintendent Hersey Meter Company; C. J. Underwood, Jr., ENGINEERING AND BUILDING RECORD; W. H. Ward; E. B. Williams, Fairbanks, Brown & Co.; A. W. Worthley, Manager American Frost Meter Company, Boston, Mass.

Timothy Woodruff, Superintendent, Bridgeton, N. J.

B. F. Steben, Manager, Brockville, Ontario, Canada.

Desmond FitzGerald, Superintendent, Western Division Boston Water-Works, Brookline, Mass.

F. H Crandall, Superintendent; F. H. Parker, Commissioner; Mrs. F. H. Parker, Burlington, Vt.

Willis E. McAllister, Superintendent, Calais, Me.

L. M. Hastings, City Engineer; Hiram Nevons, Superintendent; Mrs. E. B. Nevons, Cambridge, Mass.

A. H. Austin, Illinois Malleable Iron Company, Chicago.

H. H. Lowe, Superintendent; John F. Philbin, Water Registrar, Clinton, Mass.

James C. Bayles, President Spiral Weld Tube Company, East Orange, N. J.

William M. Hawes, Water Commissioner; Patrick Kieran, Superintendent; Weaner Osborne, Commissioner; William Walfemehl, Fall River, Mass.

Thomas C. Lovell, Superintendent, Fitchburg, Mass.

G. A. Roullier, Superintendent, Flushing, N. Y.

Charles W. Morse, Superintendent; Levi C. Wadleigh, President Aqueduct Company, Haverhill, Mass.

R Pattee, Holyoke Hydrant and Iron Works, Holyoke, Mass.

Edward L. Ross, Chapman Valve Manufacturing Company; Mrs. Edward L. Ross, Indian Orchard, Mass.

A. H Salisbury, Superintendent, Lawrence, Mass.

M. F. Brennan, Commissioner; W. A. Dickinson; Charles H. Hobson, Superintendent H. R. Barker, Manufacturing Company; Thomas Mather, of the H. R. Barker Manufacturing Company; Clarence H. Nelson, contractor; Arthur F. Salmon, Member Water Board; Millard F. Wright, Superintendent, Lowell, Mass.

Solon M. Allis, Superintendent, Malden, Mass.

Charles K. Walker, Superintendent, Manchester, N. H.

Fred B. Gleason; Robert D. L. Mortimer; James T. Murphy, Water Commissioner; George A. Stacy, Superintendent, Marlboro, Mass.

R. M. Gow, Superintendent, Milford, Mass.

Horace G. Holden, Superintendent, Nashua, N. H.

Carrol Ph. Bassett, civil engineer, 784 Broad Street, Newark, N. J.

R. C. P. Coggeshall, Superintendent; Mrs. R. C. P. Coggeshall, New Bedford, Mass.

J. W. Ringrose, Secretary, New Britain, Conn.

Edward H. Phipps, Superintendent, New Haven, Conn.

Walter H. Richards, Superintendent, New London, Conn.

E. W. Cate, President Water Board, Newton, Mass.

E. L. Abbott, Water Waste Prevention Company; Jarvis B. Edson, manufacturer; Alphonse Fteley, Chief Engineer, Aqueduct Commission; W. M. Geiring, Fairbanks, Brown & Co.; George H. Frost, *Engineering News*; Mrs. George H. Frost; Rudolph Hering, civil and sanitary engineer; John C. Kelley, Jr., National Meter Company; Henry C. Meyer, Editor THE ENGINEERING AND BUILDING RECORD; F. W. Shepperd, *Fire and Water*, New York, N. Y.

Horatio N. Hyde, Jr , Superintendent, Newtonville, Mass.

Jonas M. Clark, Superintendent, Northampton, Mass.

W. H. Whitcomb, President Water Company, Norway, Me.

T. J. Dibble, Standard Thermometer Company, Peabody, Mass.

Jesse Garrett, R. D. Wood & Co., Philadelphia, Pa.

Charles R. Dyer, Superintendent Meter Department; E. R. Dyer, Portland Water Company; George P. Westcott, Treasurer Water Company, Portland, Me.

Samuel M. Gray, civil engineer; Benjamin S. Terry, (A. W. Harris Oil Company) Providence, R. I.

Lewis M. Bancroft, Chairman Water Commissioners, Reading, Mass.

Nathaniel Dennett, Superintendent; Horace L. Eaton, City Engineer, Somerville, Mass.

A. E. Martin, Superintendent, South Framingham, Mass.

A. G. Pease, Superintendent, Spencer, Mass.

William J. Ranton, Superintendent Porter Manufacturing Company, Syracuse, N. Y.

William R. Billings; George F. Chace, Superintendent, Taunton, Mass

William Hamilton, Superintendent Water-Works, Toronto, Ont.

George Cross; Octavious Jones, Rensselaer Manufacturing Company, Troy, N Y.

Charles A. Barton, Water Commissioner; George E. Winslow, Superintendent, Waltham, Mass.

Fred A. Volk, Superintendent, Ware, Mass.

James L. Lusk, Captain Corps of Engineers, U. S. A., Washington, D. C.

Frank W Whitlock, Assistant City Engineer, Waterbury, Conn.

H. D. Winton, Engineer Hersey Meter Company, Wellesley Hills, Mass.

John C. Whitney, Water Registrar; E. T. Wiswall, Water Commissioner, West Newton, Mass.

George J. Ries, Superintendent, Weymouth Center, Mass.

Albert P. Barrett, Water Registrar; P. F. Crilly, Superintendent, Woburn, Mass.

Frederick W. Wilder, Treasurer Aqueduct Company, Woodstock, Vt.

George E. Batchelder, Registrar: George H. Carr, Union Water Meter Company; W. H. Moulton, Union Water Meter Company, Worcester, Mass.

Joseph A. Lockwood, Superintendent, Yonkers, N. Y.

The exhibits, under the management of Charles R. Dyer, of the Portland Water Company, were as follows:

Chapman Valve Manufacturing Company, Indian Orchard, Mass. Valves, Hydrants, etc.

American Frost Meter Company, Boston Water Meters.

Hersey Meter Company, Boston. Water Meters.

Union Water Meter Company, Worcester, Mass. Water Meters and Water Pressure Regulators.

Fairbanks, Brown & Co., Boston. Gate Valves, etc.

Whittier Machine Company, Boston. Water, Steam and Gas Valves.

The H R. Barker Manufacturing Company, Lowell, Mass. Water Motor, Pipe Fittings, etc.

Standard Thermometer Company, Peabody, Mass. Electrical Recording Gauges.

Holyoke Hydrant and Iron Works, Holyoke, Mass. Hydrants.

Porter Manufacturing Company, Syracuse, N. Y. Water Filter.

Peet Valve Company, Boston. Valves, etc.

Belknap Water Motor Company, Portland, Me. Water Motors, etc.

Illinois Malleable Iron Company, Chicago. Improved Cast-Iron Extension Stop-Cock Boxes.

Perrin, Seamans & Co., Boston. Railroad Supplies.

W. H. Gallison, Boston. Pipe Fittings, etc.

AT the recent annual general meeting of the English Institution of Civil Engineers the reports showed that during the past year there had been elected 3 honorary members, 32 members, 263 associate members and 3 associates, while one member had been reinstated. There were 87 deaths of members, and 51 names had been removed from the list from other causes. The total number of members is now 5,872, and the gross income of the Institute last year was £22,478. When the Institute was chartered, 67 years ago, it had 156 members and its annual income was £447.

CONSTRUCTION OF PARIS SUBWAYS IN SEWERS.

THE system of large sewers begun in Paris as early as 1851 proves each year the far-sightedness of the originators of the plans of laying all the water mains in an accessible subway. As early as the time of the first Empire a sewer 6 feet wide and 6 feet high was built in the Rue St. Denis, in which a 10-inch water-main was laid on projections of the side walls. Later, Mr. Mary, Director of Water and Sewer Works, increased the minimum width of sewers to 32 inches, which would allow of 3 and 4 inch mains being laid in the upper part. Up to this time all the sewers had been built of cut-stone masonry, the minimum thickness being 1 foot, but in 1851 Mr. Mills, one of the engineers of the department, advocated a sewer section of an oval shape outside, as well as inside, the walls being only 6 to 8 inches thick. Previous to this all the sewers had been built with side walls vertical on the outside. The oval section was adopted from London sewers, only applied to larger sections. Then Engineer Watier suggested for large intercepting sewers, a section with offsets on the inside forming sidewalks, with angle irons on the edge to be used as tracks for hand cars. The width of 4 feet between tracks suggested by him has been adopted in all the large sewers built since, and the side projections, besides being used as walks, form a support for the columns on which the water mains are laid.

Thus the dimensions of the Paris sewers are generally regulated, not by the amount of sewage liable to flow through them, but by the size of water mains that must be laid through any particular section. It is only in the largest intercepting sewers that the amount of sewage flow is considered in determining the size of the sewers. Mr. Belgrand, who laid out the present system of Paris sewers, and lived to see the larger portion of his works built, divided the sewer sections into 12 standard types, which form the normal basis for laying out the sewers of the city. The special type for a particular street is chosen with regard to the sizes and probable number of water mains needed for future use, and the grade. A few modified types have been twice added for special cases, but the 12 regular types are generally used, as shown in Table I. Water mains up to 24-inch are set on brackets; others on posts.

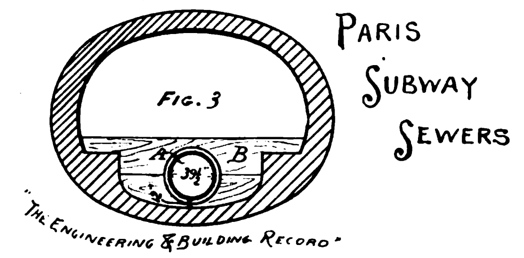
All these sewers or subways are built of rough limestone laid in beds of Vassy cement mortar with inside and outside coatings of cement mortar, the waterway being laid in Portland cement. The thickness of masonry varies from 8 to 20 inches at the top of the arch.

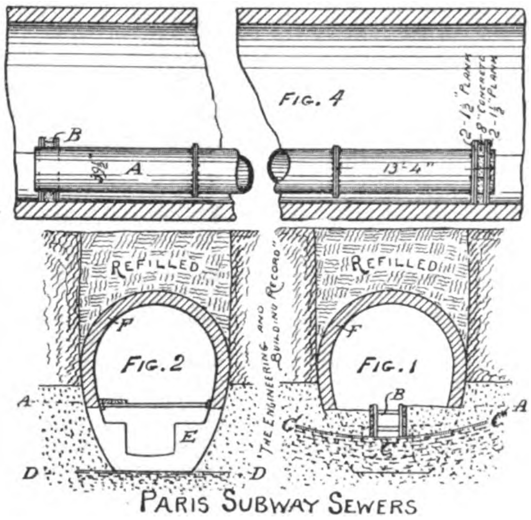
It has always been a rule to exclude all gas pipes from the sewers owing to danger of explosions from leaks and the presence of light used by the water-works or sewer laborers. But pneumatic tubes of the postal and telegraph department, electric wires of telegraph and telephone companies, and some electric light wires find place along the intrados of the arches. The space along the intrados is divided up between the telegraph, fire departments and telephone companies, which pay rent for six 12-inch rights of way which can contain some 350 lines. (See Vol. X., page 221, of this journal.) When the question of allowing all house sewage to run directly into sewers came up it was proposed to lay a small tile or stoneware pipe, closely fitted to the bottom of the waterway, thus forming a separate system, to reduce the amount to be pumped up for land treatment.

TABLE I.

Types.	Width.	Height.	Water-Way.	No and Size of Water Mains.	Remarks.
No 1	18' 8"	14' 8"	140" × 54"	....	No water pipes in main sewer to outfall.
" 2	17' 4"	17' 10"	48" × 38"	2 up to 44" in diameter..	Bv. Sebastopole.
" 3	13' 4"	13'	88" × 32"	2 up to 24" in diameter..........	Quai's.
" 4	12' 4"	12' 4"	48" × 28"	1 up to 44" and 1 small pipe.... .	Br. St. Michel.
" 5	10'	12' 8"	48" × 28"	1 up to 32" and 1 up to 24".	
" 6	8' 4"	10' 6"	32" × 14"	1 up to 44" and 1 small pipe.... .	
" 7	8'	11' 10"	48" × 28"	2 up to 16" and 1 small pipe...	
" 8	7' 8"	9' 4"	48" × 16"	2 up to 24" and 1 small pipe......	
" 9	8'	9' 2"	30" × 16"	1 up to 32" and 1 up to 12".......	
" 10	7'	8'	oval sect.	1 up to 24" and 1 up to 8"	
" 11	5'	7' 2"	"	1 up to 16" and 1 small pipe... ..	
" 12	4' 4"	7' 8"	"	1 up to 16" and 1 up to 4"	Ordinary type.

With this system of subways a great part of the digging up of streets common in other cities is avoided. Once a sewer is built in a street all the water main and house connection work is done in the sewer itself. The pipes are brought into place on trucks running on tracks laid in the sewer, after being loaded into the sewer from either one of the extremes on the quais or from an opening cut down from the street into the sewer. There being no irregular settlement somewhat lighter pipe can be used for the mains, which are all connected with short collar joints that can be easily driven off in case of any change to be made in the main.





PARIS SUBWAY SEWERS

In many places the soil in which these sewers were to be built was fine sand; but by lowering the ground water this sand stood well in cuts and Mr. Belgrand devised a method of construction as follows: The upper portion of the sewer, down to the level of the ground water, was built in open trench and the trench refilled. Then, by means of wells some 330 feet apart, dug below the bottom of the invert foundations, pumps were applied and the ground water lowered on the line of the sewer. Then by sheathing and bracing a trench was gradually dug down inside the sewer, between two consecutive wells till the water line was drawn below the foundation line. In this way it was possible to excavate for the lower portion of the sewer, which was built up in 13 foot sections, the only timbering required being a line of rangers on either side at the foot of the masonry previously laid in open trench, with cross bracing every 6 or 7 feet. Planks laid on this bracing served for a foot and rollway for bringing and removing materials. The main outlet collector was built in a similar way, but all in tunnel. The ground water was lowered sufficiently to allow of a rat-hole being dug, 32 by 64 inches from well to well, without timbering. This was then enlarged to 8 feet by 8 feet 8 inches, with timber frames every 5 feet, and finally widened out to 22 feet, the full width of the excavation, the centers set and the top arch of masonry built up. The lower half of the sewer was then excavated, as previously described, and masonry built in 13 to 20 foot sections, working both ways towards the pump wells.

This method is shown in Figs. 1 and 2 where the upper part, F, of the masonry was first built in a trench excavated only to the level A A, of ground water.

The ditch B was then dug, and reduced the ground water level to C C C, and finally to D D, Fig. 2, when the remaining excavation was made, and the rest of the masonry, E, put in in sections.

When the lining of the waterways of the larger sections needs repairs M. Darcey's method is used to have dry work and yet allow the sewage to flow.

This method was first used for repairs on the large collector. Four lengths of Chameroy pipe A (Figs. 3 and 4) (a sheet-iron pipe $\frac{3}{16}$ inch thick, coated inside and out with asphalt,) were used. Each pipe was 13 feet 4 inches long, 39½ inches in diameter, and weighed 1,375 pounds. They were joined together by bolted collars and tar felt packing. The ends were closed by wooden stoppers cut out of three thicknesses of 1⅝-inch plank nailed together and the whole floated into place. Here bulkheads B, formed of two thicknesses of 1⅝-inch plank, were fitted around each end and 8 inches of concrete run in between. The whole flow of the sewer was thus run through the pipe, leaving a clear space under it of a foot in which to make the repairs. The cost of the pipe was $360. The total cost of repairs at this and one other place further down the sewer, which was made by floating the whole pipe, dams and all, down the sewer, amounted to some $680.

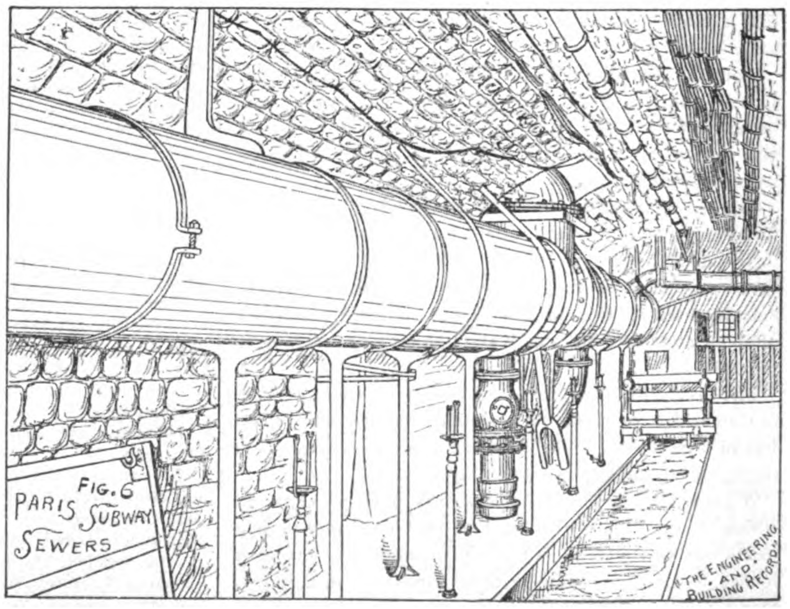
PARIS SUBWAY SEWERS.



The Engineering and Building Record

FIG. 6
PARIS SUBWAY SEWERS

Figures 5 and 6 are prepared from photographic views of the interior of important sewers, and clearly illustrate the arrangement of pipe lines, etc. Figure 5 is a view in the Gallery Sebastopole at the junction of the Rue de Rivoli, and Fig. 6 is a view of the Chatelet chamber. Each shows mains for spring water and pipes for pneumatic postal service; also blow-offs, gates, footways and telegraph wires. Figure 5 also shows a main for canal water, telephone wires, the iron car track and turntable over the sewer way, and the intersecting pipe lines, etc., of the cross street. Figure 6 shows, also, lamp posts and a visitors' car.

MILL CONSTRUCTION.

In a paper entitled, "Methods of Reducing the Fire Loss," read at the last meeting, at New York, of the American Society of Mechanical Engineers, C. T. H. Woodbury referred to modern mill construction as follows:

In its design, a mill for any standard line of manufacture is not a building whose arrangement and proportions are fixed upon at the whim of the owner, but they must conform to certain conditions of dimensions, stability, light, and application of power to satisfy the requirements essential for producing the desired results at the lowest cost—circumstances and conditions to which capital has been mercilessly starved by close competition and the encroachments due to growing socialistic tendencies. As methods of manufacture change, so mill construction must in like manner be altered to conform to the new conditions.

Whatever changes may be made in methods of construction, the question of the fire hazard continues to be represented by an annual charge which differs from the other fixed charges of interest in that its ratio is a variable one and is based upon the estimated annual chance of fire. The more efficient the manner in which such a building can be arranged to resist fire, by so much will the hazard represented by the insurance premium become less.

Although a great deal depends upon construction, this hazard can never be reduced to zero, as that would indicate that the mill was absolutely fireproof. A fireproof mill, both in name and reality, must not only be built of incombustible material, but must also be capable of resisting any fire of its contents without destructive effects upon the structure. Such a building would be a commercial impossibility, both in regard to prohibitive costs and also the hindrances to manufacturing involved by a method of construction which would bear comparison with the casemates of fortifications, and is therefore unsuited to the conditions essential for the advantageous operation of machinery. It is apparent that the name of fireproof mills never deceived anybody, for the owners keep them insured, and the insurance companies charge a rate in accordance with their estimate of the hazard.

The destructive results attending fire in such buildings, whose iron and masonry construction is called fireproof, shows that some other form of construction is necessary to obtain the desired result of minimizing the annual cost of the maintenance of the invested capital, as represented by insurance, depreciation, interest, and taxation. There is little incentive for entering into unusual expenses in the construction of a manufacturing building for the purpose of increasing its resistance to fire, unless the additional interest on such increase in the investment is to be met by a corresponding reduction in the annual cost of the fire hazard. In addition to these questions involving the annual maintenance of the plant, the increase in the expense of the building above a certain point may prove poor management by locking up capital for too long a time, and may tend to prevent the improvements in arrangement and construction which are necessary for the most advantageous manufacturing.

The method of mill building known as slow-burning construction combines the advantages of low initial cost and great resistance to destruction by fire, the final result being that the manufacturing process is housed at the minimum annual cost.

The principal features of slow-burning construction may be illustrated by bits of experience drawn from many sources. The fundamental principle of such construction is to mass the material in such a way that there shall not be any concealed spaces about the structure, and that the number of projections of timber which are more easily ignited than the flat surfaces shall be reduced as far as possible: that iron portions of the structure shall not be exposed to the heat of any fire in the contents of the building, and furthermore that the isolation of the various portions shall be as complete as is feasible—both as respects one building to another and the various rooms and stories of the same building to each other.

Some of the more salient features of modern mill construction pertaining to questions of resistance to fire can be briefly related. Without entering upon the general subject of mill construction, the most important feature is that of the mill floors, which should be laid on beams, generally of southern pine, 12 by 14 inches, or 2 inches larger when required by unusual loads or longer span than 22 feet. These beams are placed from 8 to 10 feet apart between centers, and it is preferable that they should be made up of two pieces bolted side by side, with small blocks interposed to provide an air space of about an inch, as this will diminish the tendency to decay or to twist as the result of long continued seasoning. At the anchorage of the walls the beams should rest upon cast-iron plates secured into the walls and provided with a rib on the top 1½ inches in height projecting into a wide groove across the bottom of the beam and brought to a firm bearing by a pair of wedges driven into a groove each side of the iron tongue. It is important that an air space should be left in the wall each side and at the end of the beam to prevent dry rot, and that the bricks in the wall for about four rows immediately above the beam should be laid in dry sand. A preferable modification of this is to use a cast-iron box made to receive the end of the beam and separated from contact on the top, end and sides of the beam by ribs projecting on the inside of the box. As in the former case these iron supports are securely built in the wall. This arrangement is much more stable in anchoring the beams to the wall, and if by reason of fire the beams break they will slide out from their anchorage without injury to the wall as soon as the groove on the bottom of the beam clears the rib in the supporting plate.

At the columns, beams rest on cast-iron caps which should present a supporting area at least three times that of the cross section of the wood columns used, as the resistance of timber to longitudinal crushing is three times that of its resistance across the grain. The support from one column to the next should be made by cast-iron pintles, preferably those whose section is in the form of a Greek cross, as that presents advantages in the way of securely joining them to the wood columns. At the top of the pintle, a cast-iron plate should support the base of the column above. A flat plate with a projection in the middle securing the column by insertion into the core of the column is preferable to the cup form which is so frequently used, as the latter tends to retain moisture to the deterioration of the column by dry rot.

Timber columns are preferable to those of iron, unless the load is greater than can be sustained by timber—the limitation of a load on oak or southern pine of straight grain and free from knots being about 600 pounds to the square inch. Such columns, when subjected to destructive tests, give way by direct crushing, and for this reason the tendency of late years has been to make square instead of round columns. These offer no greater obstruction to the floor than the round columns and give about one-fourth extra resistance. Whenever the amount of load renders it necessary to use iron columns, they should be protected by wire lath and plaster or by some of the special tiles made for the purpose.

The floor planks for this type of floor are generally made of spruce plank from three to four inches in thickness, grooved on both edges and joined together by hard wood splines. These floor planks should be two bays in length, breaking joints at least every three feet.

Above this the top floor, of one 1¼ or 1½ inch hard wood is laid; and in some instances the resistance of the floor to fire is greatly increased by laying a coat of plaster on the floor plank before the top flooring is put on. But the general method of increasing the resistance of the floor to fire, is to cover the floor and beams on the under side with plaster laid on wire lathing. When anything of this kind is done care should be taken that the covering to the timber should not be hermetically sealed, as that course increases the tendency to dry rot, particularly if the timber is not thoroughly seasoned at the time of its application. There have been a number of failures of the strength of such construction on account of the disregard of this well known principle that it is not desirable to seal up the outside of unseasoned timber. This not only applies to the method cited above, but also to paints and varnishes which are laid on such work before it is thoroughly seasoned.

In mill floors of very large area care should be taken that the transverse shrinking of the floor should not pull the walls; and on large low structures which are far enough across to be affected by a very slight longitudinal shrinkage of the beams, other methods of anchorage than the one referred to should be adopted.

The mill roof is similar to the floor in many of its characteristics, the timbers being somewhat lighter. If the roof is higher in the middle the beams extend through the wall, and their ends properly cut serve as brackets for the roof planks which are continued to the ends of the beams, and thus make a finish without calling for the construction of hollow cornices with gutters.

There will be no trouble from condensation on such a roof in cold weather if the plank and roof boarding are three inches in thickness, unless some wet process be carried on which produces a large amount of vapor, like paper manufacturing; in this case it is advisable to make the roof four inches in thickness, also placing roofing felt between the plank and the roof boarding.

If it is desired to add finish by placing sheathing against the underside of the roof plank, such finish should be blind nailed, as the nails are good conductors of heat, and reaching to the colder portion of the roof, the moisture in the air will condense on the nail heads if exposed. It was formerly assumed that a double, sloping, hollow roof was necessary over a paper machine, but the above type of roof has been successfully employed for such purposes.

A coal tar concrete walk about the building will protect the foundations and also take care of water dripping from the roof. Under some circumstances the slope of the roof is reversed, being depressed at the middle and highest at the edges, the storm water being removed through gutters extending down through the middle of the building. This enables the walls to be extended above the roof, forming a parapet, which is a great defense against fire from exposure outside, and is a method of construction which is being generally followed in cities.

Such a mill floor and columns, while possessing in a very high degree features which offer resistance to fire, and are weakened only to a slight extent as they are slowly burned away under exposure to a very severe fire, also possess the merit of great economy, both as regards the low price of construction, and in that the floor is thinner in comparison with joisted floors of equal strength, saving in this respect for every floor in a building about 10 inches in height of wall, stairs, belting, steam pipes, and all vertical connections reaching from floor to floor—a saving which amounts to considerable in the total cost of building.

It is important, however, that floors should not be pierced with unprotected openings for stairways, elevators, or main belts. There is no record of such a mill floor, without belt or other holes in it, being burned through by a fire starting in the room below.

Floors near the earth in basements should be well ventilated, if there is a space between the floor and the surface of the earth; but, unless that space is continuous and 2 or 3 feet in height, it is better to lay the floor directly upon the earth, taking care to prevent dampness by putting in a layer of stones or cinders. Above this the sills for the floor are laid in a trench with coal-tar concrete, which is also laid between the sills, on a level with the top of them, and the floor boards are laid over this. When well-seasoned chestnut is used for this purpose it will last a great many years without dry rot. Cement concrete will cause timber to decay rapidly.

Windows for a mill should be placed as high as possible, as the illumination from the upper part of a room is much more uniformly diffused. The window sills should be sloping, in order that articles should not be left on them in a disorderly manner. The architectural effect is usually heightened by placing sashes as near to the line of the inside of the wall as possible, making the disclosure or opening around the sash on the outside as large as possible. Ventilation can generally be arranged more satisfactorily by means of stationary sashes, the upper part of which swings like a transom over a door. In places where the work will be disturbed by currents of air, a desirable form of window ventilator is made by deflecting a portion of the middle of the sash—about 18 inches in height and of same width—inward into the room, covering the top of the bracket-like projection thus formed with a cover which can be opened at will. The air from the outside is directed upward toward the ceiling, thus giving a uniform circulation in the room without causing rapid currents. In case the windows admit too much light, this can be readily modified by painting the inside of the windows with a mixture of turpentine with zinc white. The amount of obstruction desired can be readily fixed upon after a few trials.

In one-story mills, and in the upper stories of wide mills, it is necessary to introduce light through the roof. While the expensive English ridge and furrow roof gives a very soft and blended light, it is hardly adapted to the northern part of the United States, on account of the difficulties with snow, and monitor roofs or hipped skylights give the best satisfaction. If the latter are used, it is desirable in many instances that the lower part of the space under the skylight be separated from the room below by means of glazed sashes, placed flush with the ceiling. The monitor roof of a one-story machine shop affords an opportunity for a traveling crane with a minimum of building space.

Stairways should not be placed in direct communication between different stories of the mill, but in masonry towers, with substantial doors at each story. Stairways should be made in straight runs with square turns rather than spirally.

Elevators should be so arranged that they would not serve as a flue under any circumstances; but it is not necessary to place them in a tower outside of the building as elevators through any portions of mills can be safely placed at almost any point desired for sake of convenience, and the openings kept closed by means of automatic hatches.

The division of mills into various portions by means of fire walls is frequently not so efficient as assumed, by reason of the lack of fire doors to fulfill satisfactorily the purpose of resisting fire. The best form of fire door is that made of two thicknesses of matched boards, placed at right angles to each other and nailed together, being covered on the outside by tin, securely locked together and held to the door by numerous hanging strips. The door should be secured to the hangers by means of bolts, and not screws, and the rail upon which it runs should be strongly bolted to the wall. When closed, such door should fit into a jamb and be securely held in this manner against the wall. Such doors are frequently hung upon an inclined track, and, by some application of highly fusible solder at the catch, are so arranged that they will be closed by the heat of a fire, if not closed by hand. This same principle may be applied to fireproof shutters hung over various openings which necessarily exist in walls which are desired to form a fireproof separation between various portions of a building. A fire wall must extend through the roof, cutting off continuity of woodwork, especially at the roof cornices. The top of such a fire wall can be covered with tiling, which is made in special form for such purposes, better than by a stone coping.

In this treatment of the arrangement of buildings to resist fire, consideration has not been given to the cost of land, which is of itself an important factor in determining what arrangement will be the most expedient for an establishment. Where land is expensive, or where there are limitations in the space suitable for building, it is frequently necessary to build mills and shops higher than would be preferred under other conditions; but where circumstances will permit it, the one-story mill has been very successful, not merely in immunity from fire and very low cost per square foot of floor, but also in the advantages of manufacturing, particularly in regard to cost of supervision and movement of the stock in process of manufacture. These are questions which must be determined, not merely in regard to the various processes of manufacture, but the individual needs of each concern; the position of the fire risk in the matter being that the hazard of a building increases very rapidly with its height and to some extent with its area. The extension of one-story buildings over too large an area will not be commended, and certainly as regards the question of fire, it has a tendency to place too large a property in direct exposure to a very wide hazard.

Some textile mills have been built in the form of the block letter U, this form having been decided upon as giving the conditions of lowest resultant cost. One wing two stories in height, contains weaving; the other wing, three stories in height, contains carding and spinning; while the engine is placed in the connecting building. The pickers and the boilers are in outside buildings, so placed that they will not interfere with future extensions of the building into the form of the block letter.

In this connection there is but little reference to be made to storehouses, except to mention the necessity of the closest supervision of their contents. The preferable arrangement of stairways and elevators for such structures of more than one story in height is to place them in towers upon the outside of the building, not directly connected to the rooms, but reached by means of open galleries which lead from the door of the storehouse to a corresponding door in the tower at the same level. It is very important that the floors of storehouses should be made as tight as possible and provided with scuppers with swinging covers on the outside to discharge any excess of water thrown on them in case of fire.

A POOR TYPE OF HIGHWAY BRIDGE.

In Syracuse, N. Y., one of the principal streets is carried over the Erie Canal in the heart of the city by an old bridge, some of whose features are here shown, to illustrate the kind of design and constructien that was once accepted for an important structure and is yet allowed to remain in responsible service in a conspicuous place.

A prominent civil engineer of central New York said that this particular design was of frequent occurrence in that region.

Figure 1 is a diagram plan of half the bridge which is symmetrical about the center line C C, and carries two street car tracks, besides carriageways and sidewalks. E E are masonry abutments; D D, etc., are floor beams, and A, B and B are trusses with lateral bracing only between the outside pairs, as shown.

Figure 2 is a diagram of the heavy truss B, with cast-iron top chord and vertical posts, the latter I-shaped in cross section.

Figure 3 is a diagram of the sidewalk truss A with cast-iron top chord and web member connections at A and B, as shown in Figs. 4 and 5.

Figure 4 is a vertical longitudinal section through the top chord M at B, and Fig. 5 is a vertical cross section through the top chord at B. L and L are wrought-iron collars.

Figure 6 shows the details of a lower chord connection at the first, and Fig. 7 at the second panel point from the abutment.

Figure 8 shows vertical and horizontal elevations of Fig. 7. C, Fig. 6, is the cast-iron vertical post and D is the floor beam. B and B are lower chord bars passing loosely through the cast block F, and E E are lateral rods.

In Figures 7 and 8 D is the floor beam and I the cast-iron pin which was in several instances twisted several degrees from its proper position perpendicular to the axis of the bridge, so as to make with it the considerable angle x, as shown in Fig. 8.

H H, etc., are the lower chord bars lying in a slight groove at the end of the pin to which the laterals were secured by a tap bolt J. G G are main diagonals.

The illustrations are made from sketches of the structure and not from working drawings.

THE PROPOSED WATER-WORKS AT NEEDHAM, MASS.

Louis E. Hawes, Engineer to the Board of Water Commissioners of the town of Needham, Mass., in his recently issued report on the proposed water-supply system for that town, gives the following particulars:

A large collecting well, 22 feet in diameter and 22 feet deep, excavated at the Colburn Springs, stoned and bricked up in such a manner as to exclude surface water, thus insuring the entire draught to be from the water-bearing stratum below, roofed over and graded about is to be connected with pumping machinery located in a brick station, from which the water will be forced through a 10-inch cast-iron main in a straight line to Needham Common; thence to the top of Ryan's Hill, where it will enter a wrought-iron reservoir or stand-pipe.

The pumping station is to be built of brick, of sufficient size to accommodate two pumps and two boilers, and will have a chimney high enough to furnish draught at all times. The pumping engines will be of the compound condensing type, two in number, and each capable of doing the entire work. It is advisable to have two, as daily pumping will be required, and if an accident should happen to one no delay will be occasioned which might otherwise prove embarrassing. The street mains are to be of cast iron, from 6 to 12 inches in diameter, one short line only of 4-inch being used to complete a circuit. There will be 7.7 miles laid in the streets, and extensions can be made in outlying localities as the needs become apparent. At intervals along the lines are to be situated 57 hydrants, each having two 2½-inch nozzles and 6-inch connection; in addition to these there will be two large post hydrants, having four 2½-inch nozzles, with independent shut-offs and 8-inch connection, located, one at Needham Common and one at Highlandville Common. There will also be stop-gates, for the purpose of isolating any section of piping needing repairs. The sizes of the leading mains are so proportioned from the reservoir that with a pressure from high water elevation 350 feet above mean low tide in Boston Harbor, they are capable of furnishing at Needham or Highlandville Commons water enough for six 1⅛-inch fire streams or eight 1-inch, or ten ⅞-inch streams doing excellent service and maintain an efficient pressure at the hydrants while the streams are flowing and domestic consumption continues.

The reservoir is to be of wrought iron, 25 feet in diameter and 85 feet high, having a roof and holding, when full to high water mark 3 feet below the top, 301,000 gallons.

The reason for proposing an iron reservoir instead of an earthen one is that spring water deteriorates when exposed to light in an open reservoir, and an earthen reservoir covered with masonry is an expensive affair. The 2,000,000 gallon one about to be built at Newton being estimated to cost $51,750.

High water in the reservoir will be 350 feet above mean low tide in Boston Harbor, 84.2 feet above Newton's present reservoir, 30 feet above high water proposed for their new reservoir, and 26 feet higher than the Wellesley reservoir.

This will give a head at Highlandville Common of 164 feet, or 71 pounds pressure, and at Needham Common of 182 feet, or 79 pounds pressure per square inch.

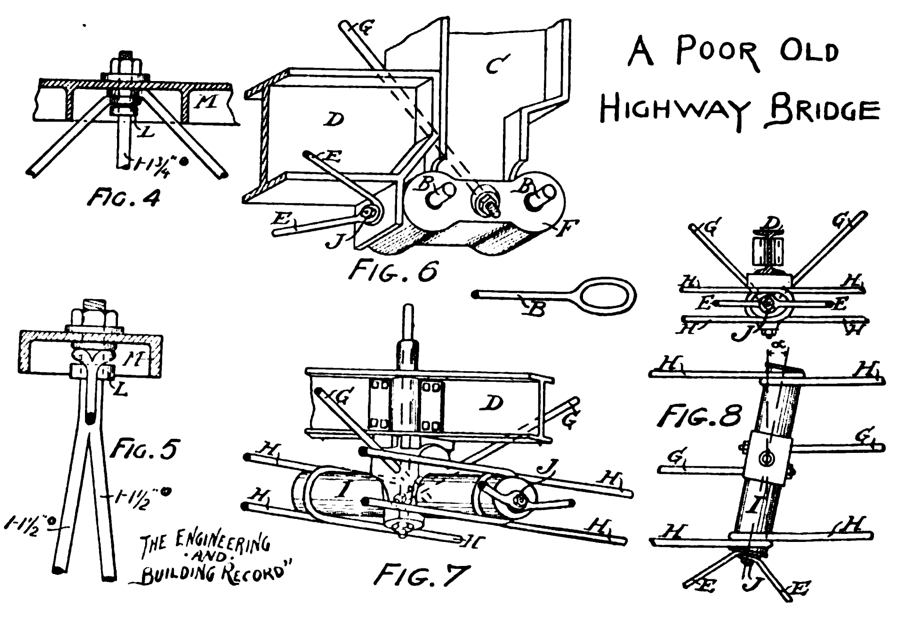
THE ONTON SUBMERGED RAILWAY.

The submerged railway at Onton, near Bilbao, Spain, which was built for facilitating the shipment of iron ore, has recently attracted considerable attention.

According to the different accounts published, the coast adjacent to the Onton iron mines is high and rocky, exposed to the full force of the sea, there being no harbors in the immediate vicinity. At the foot of the rocks there is an evenly sloping shore, which extends out to a considerable distance. It is upon this incline that a submerged track has been laid. The roadbed of the railway has a length of about 650 feet, and a width of 20 feet, upon which two sets of tracks, each of a gauge of 3 feet 3 inches, are placed, constituting a 4-rail railway. The slope is 5 feet per 100. The car which traverses this railway, and upon which the ore is conveyed from the cliffs to the ships, consists of a high iron tower made in the form of a pyramid, having a wide triangular base, and mounted on wheels, which run upon the quadruple railway track. The platform of the tower, upon which the load of mineral is placed, rises about 70 feet from the track, a height which is sufficient to raise it above the decks of ordinary vessels when the tower is run alongside. This great rolling tower is operated automatically. It is connected to the shore by means of a strong wire cable, which passes over pulleys secured to the rocks. At the landward end of the cable there are attached some weighted trucks which move up and down upon an incline. These form a counterbalancing weight for pulling the tower, when empty, in towards the shore.

The mineral to be loaded upon the vessels is brought from the mines, which are not far distant from the coast, by a rope railway. From the mineral dumps upon the heights the mineral is conveyed part way down the cliff through a shoot, the end of which projects beyond the cliff, and when the empty tower is drawn to shore by the

A Poor Old Highway Bridge



weighted trucks it automatically opens an end gate in the shoot, when the mineral drops upon the platform in a continuous stream until a weight of ore (about 100 tons) sufficient to overcome that of the counterbalancing weighted trucks has fallen upon the platform. When this takes place the tower, by its own gravity, begins to move down the inclined railway, and the gate of the shoot automatically closes. The tower continues to glide down the inclined railway through the water until it reaches the side of the ship, which is anchored fore and aft, and then by a throw of the lever, the platform of the tower being inclined, the whole load upon the platform is almost instantly deposited upon the ship, going down through slides into her hold. As soon as the discharge of the load takes place the counterbalancing trucks begin to draw the tower inward again towards the shore, and thus the operation of moving the tower backwards and forwards automatically, and automatically loading and discharging it, is carried on with the greatest regularity. About 5,000 tons of ore per day can be put on board ship by means of the railway, which can be worked, it is stated, even when the sea is very rough. The total cost of the railway and shipping arrangements is said to be less than $20,000. The railway has been designed by, and constructed under the superintendence of, Senor D. M. Alberto de Palacio.

MISSISSIPPI RIVER WATER.*

By the courtesy of Major Mackenzie, Corps of U. S. Engineers, I am enabled to give some results of experiments to ascertain the amount of sediment held in suspension by the waters of the Mississippi River at Burlington, Iowa, in 1879. During the months of April, May and June the water was taken from the river in a sediment measure constructed especially for this purpose. The measure consists of a hollow steel cylinder closed at the top and bottom by fixed brass plugs, the top plug being provided with an opening closed by a conical valve which is held firmly to its seat by a spiral spring, and by means of a cord attached and brass clamps is opened as desired. The measure may be attached to a pole and lowered to any depth desired. The water was taken at depths of 1 and 12 feet below the surface at a point where the water was 18 feet deep. The amount of water obtained at each observation was equal to the capacity of the measure, which was found to be 2,375 grains. The water was emptied into glass jars and allowed to settle. After having settled a given time it was syphoned off, except about half an inch in the bottom of each jar. The syphoned water was placed in a new jar for further examination, and the residual water, after being thoroughly shaken, was filtered through a pair of filter papers which had previously been carefully balanced so as to be of exactly the same weight. After the filtration the papers were dried, and the difference in weight was adopted as the weight of the sediment. The above process was repeated until no deposit was preceptible. It was found that all except clay would settle in 24 hours, and clay in about 100 hours, although in some cases the water would retain a milky appearance for a few weeks. The proportion of sediment to water is so small that a long series of observations would be necessary to give definite data.

I might add that some very extensive experiments were made at St. Louis, Mo., by James H. Seddon, Esq., C. E., on the settlement of sediment in the water supply of that city. Now as to the quality of water, it does seem to any reasonable mind that in so large a river the sewage and objectionable water it contained would be destroyed in the revolving currents of the waters and be ground up and out of existence.

We have situated on our stream cities varying from 500 to 50,000 inhabitants and from 20 to 60 miles apart. The water on analysis is found free from all objectionable water save clay in suspension and about 10 degrees of hardness. * * * The one objection to our river waters is the spring freshets, coming down in torrents, carrying a large amount of sediment and mud at these times; if a settling or storage reservoir could be had it would help most water supplies out of the difficulty.

We clean out our reservoir once a year and find the mud from one to two inches deep. The capacity of same is about 2,000,000 of gallons, and in addition to this we flush our mains about every two months, using the full opening of pipe, and in a 10-inch main, about one mile and a quarter long, it takes 15 minutes to do the work under a head of 190 feet; so you can see how much sediment accumulates in this pipe. That the river water is liable to be contaminated there is no doubt, but with such volumes of water pouring down its bed the objectionable water will have little effect on the water supply. Whether artesian well waters are more healthy than our river waters remains yet to be determined. I believe there is no data on record to show the effect of either supply on the health of the inhabitants using one or the other.

THE MANCHESTER SHIP CANAL HOSPITALS.

The hospitals here illustrated have been built by Contractor T. A. Walker at intervals along the line of the Manchester Ship Canal, for the men employed on the work. These hospitals are private institutions, built to supplement the large public institutions previously existing in each of the large terminal cities of the canal.

The buildings are of wood, with corrugated iron roofs. The upper floors are devoted to sleeping rooms and all the hospital rooms are on one level, arranged as shown in Fig. 1, which is a plan of the first story. Figure 2 is an elevation from X X, and Fig. 3 is an elevation from Z Z, Fig. 1. A is the scullery; B, coal room; C larder; D, nurses' sitting room; E, kitchen; F, doctors' sitting room; G, dispensary; H, waiting and operating room; I, linen room; J, emergency ward; K, women and children's ward; M, men's ward; L, nurses' room, commanding all the wards; N, lavatory, and V V V water-closets. S S, etc., are chimneys.

BOOK NOTICES.

The Natural Law of Relation Between Rainfall and Vegetable Life, and its Application to Australia. By Franz A. Velschow, C. E.; published by Edward Stanford, London, S. W.; price, One Shilling.

The title of Mr. Velschow's interesting paper gives almost all the information necesary for the prospective reader to form an estimate of its general character. Briefly stated, the paper gives the results and conclusions arrived at after 18 months' sojourn in the South Sea and Australia, where the author was engaged in irrigation schemes and other similar works of improvement. The striking contrast between the climates of Australia and China, the former country suffering severely from periods of drought although favorably conditioned in other respects, led to an investigation as to the probable causes. These are set forth in the pamphlet before us, together with interesting facts and comments.

Two diagrams accompany the text, illustrating the hypothesis that dried-up land is covered by an air cushion which has uninterrupted occupation of the land as long as the drought lasts, and which generally requires some extraordinary agency, such as a thunderstorm, to put it in motion.

ANNUAL REPORTS.

East Saginaw, Mich., Fifth Annual Report of the Board of Public Works; R. W. Roberts, City Engineer.

East Saginaw, Mich., has a population of 35,000, and covers 6.6 square miles. It has 91.28 miles of streets, of which 53.19 are graded, 5.18 planked, 10.39 paved, 0.33 macadamized and 16.18 unimproved; and 118.75 miles of sidewalks, of which 110.64 are plank, 1.67 concrete, 0.34 flag and 0.10 coal tar and gravel.

There are 29.31 miles of sewers and 16.15 miles of tile drains and 40.90 miles of water mains and 277 hydrants.

To look after all this, except the water-works, the City Engineer receives a salary of $2,100, and his other office expenses, including salaries of assistant engineer, draughtsmen, rodsmen, inspectors, etc., amounted to $2,408, among which is an encouraging item of $13.31 for testing cement.

The report of the Board proper is mainly a condemnation of the cedar-block pavement, and is given nearly in full elsewhere.

Of streets graded in 1889 there were 1.21 miles, costing $3,297. The price per lineal rod varied from 74 cents to $2.23, and for earthwork from 22 to 35 cents per cubic yard. Sapless cedar-block paving was laid on eight streets for a total distance of 1.08 miles, and at a cost of $20,815. In one case the cedar blocks extended the full width of the paving (38 feet), and were curbed with Medina stone, but in the other cases they only occupied the center of the street, with cobble stone gutters and curbs.

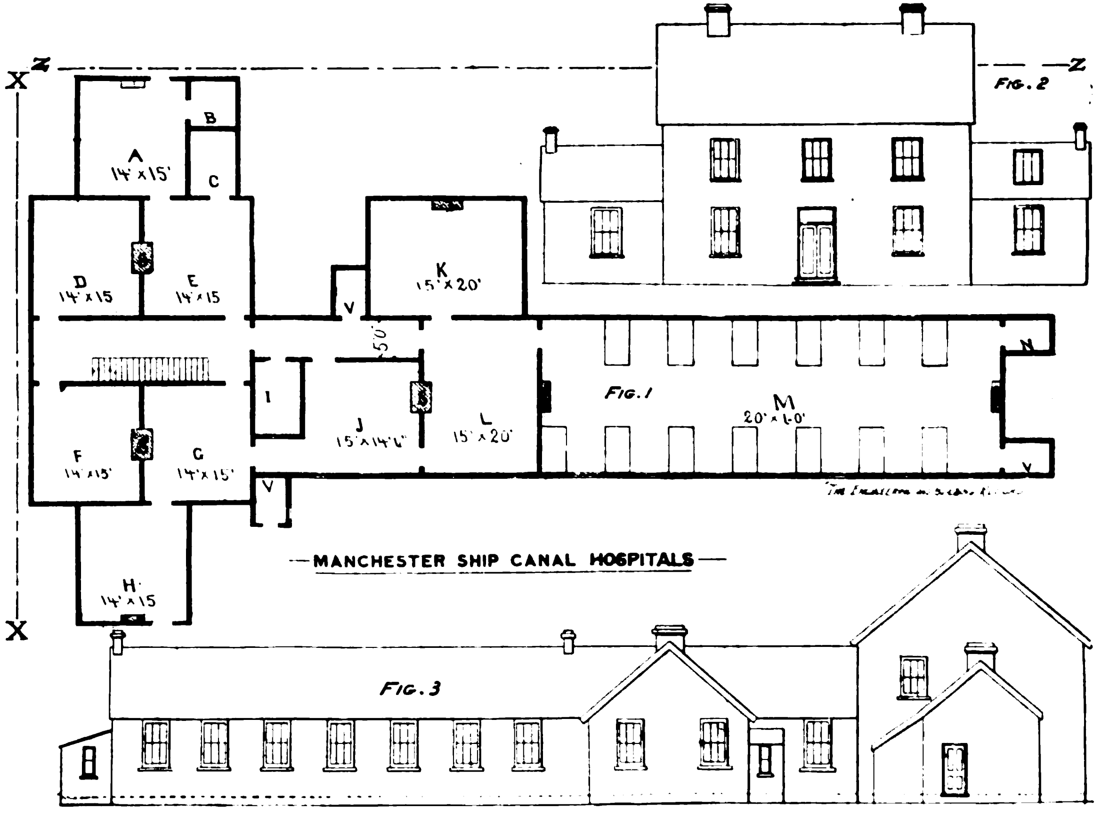
Of sewers 2.73 miles, from 50x75-inch brick to 15-inch pipe were constructed, at a cost of $33,039, and 140 new connections were made, making 2,151 in all, of which 1,279 are in actual use, and 872 are stopped at the curb. Of 3-inch tile drain under street pavements 2.04 miles was laid, at a cost of $1,657.

Permits were issued for 260 new buildings, to cost $353,648, and 142 permits for additions, alterations, etc., to cost $41,701.

The City Engineer finds one of the principal causes of deposits of dirt and sewage in the sewers to be the use of perforated manhole covers in the dirt streets, as in such cases he invariably finds dirt in the bottom of the sewer, underneath the manhole. While admitting the importance of perforated manholes for ventilation, he recommends that when used on dirt streets they be so "trapped" as to prevent the dirt from falling through into the sewers.

Annual Report of the Water Board of the City of Malden, Mass.; for the year ending December 31, 1889.

In this report the Commissioners briefly review the work of the year, and, among other matters, touch upon the equalization of water rates. Considerable space is devoted to the report of the Superintendent, Solon M. Allis, in which is given, in detail, the cost of the different branches of work performed during the year, together with a general statement of the condition of the works. A report of the "Commission on Additional Water Supply," and the report of the Water Registrar, George W. Barrett, make up the concluding portion of the pamphlet. Several illustrations accompany the several reports, one of them showing the new pumping station, and another the old pumping station at Spot Pond. In addition to these there are views of the new stand-pipe and of the new pumps, and a blue print illustrating the method of lowering a 12-inch syphon into the river.



—MANCHESTER SHIP CANAL HOSPITALS—

---

* From a paper on "Waters of the Mississippi River," by William Molis, Superintendent Muscatine, Iowa, Water-Works, presented at the Chicago meeting, May 20-23, of the American Water-Works Association.

ANNUAL REPORTS.

THE water-works report for Dayton, O., for 1889, Charles E. Rome, Secretary, shows that 9,637 feet of 4 and 6 inch mains were laid during the year, making about 51½ miles in all; 12 fire hydrants added, making 485 in all, and 531 services put in, making 2,536 in all. The amount charged to current expense account was $28,150, and to construction account $44,203, the latter amount including $38,332 paid on new machinery, which included a 10,000,000 gallon Gaskill pumping engine, put in operation during the year. There were 858,956,555 gallons of water pumped during the year and 4,020,575 pounds of coal burned. The average domestic pressure was 53 pounds, but 4,569,250 gallons were pumped against a fire pressure of 109 pounds.

THE water-works report of Lawrence, Mass., for 1889, A. H. Salisbury, Superintendent, shows that there were 6,594 feet of 1, 6 and 8 inch mains laid during the year, making 296,477 feet in all; 5 hydrants set, making 502 in all; 129 services added, making 4,713 in all, and 172 meters set, making 1,213 in all. The amount charged to maintenance account was $17,867, while $15,981 was charged to construction account. There were 960,848,662 gallons of water pumped against an average head of 183.20 feet, and 1,514,520 pounds of coal burned.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department.* Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

BEAM BRACKETS ON CAST-IRON COLUMNS.

F. GOUDARD DE LACHAU, architect, writes: "Will you kindly let me know where I could find any data in regard to the strength of shoulders—or brackets—cast with cast-iron columns in order to support beams?"

[We do not know of any published data in regard to the strength of beam brackets on cast-iron columns. If any of our readers do we should be glad to hear from them on the subject.

A beam bracket on a column is essentially a cantilever and subject to bending and shearing stresses, both of which should be calculated, although unless the bracket is unusually long the bending stress will in most cases be found to be so small as to be of little consequence compared to the shearing stress, and if the latter does not amount to more than 3,000 or 4,000 pounds per square inch the bracket will usually be safe enough if the casting is sound. In estimating the section which resists the shear the bracket should not be supposed to be sheared off clean, which would give too large a section, but the probable direction of the fracture should be estimated by the eye, as shown by the broken line on the profile of C in the figure, and only the area of the metal at that point should be considered as effective in resisting the shear or other stress.

When a beam butts against a column it will usually be necessary to provide a rib to which the web of the beam may be bolted in order to secure it in place, and if this rib G be continued around the flange of the beam, as shown, so as to connect with the bracket H it will give additional strength and security to each. If the rib runs up far enough to nearly reach the top flange of the beam it might perhaps with the bolts support the beam in case the bracket should prove defective, at least long enough to permit the danger to be averted. The rib should not quite reach the upper flange at first lest the whole load should be borne there instead of on the bracket.

The rib and bracket just described were for a 10½-inch beam. Rib I and bracket K, were for a 15-inch beam, and in this case the rib had so much projection as to require to be strengthened by two supplementary ribs, though this was mainly to prevent accident in handling.

In case the beam is tangent to the column it can be best supported on a bracket C and drawn up against ribs L L by bolts D D, with the same precautions as before against giving a bearing under the top flange.

In arranging the brackets on a column care should be taken to have the common center of gravity of all the loads coincide as nearly as possible with the center of gravity of the cross section of the column, as if these centers are distant from each other by an amount equal to any material fraction of the column's diameter, the pressures on the column will be very unequally distributed, perhaps even causing tension on one side with a tendency to fail by buckling in that direction under a much less load than could be borne with perfect safety if central.

A great danger attending the use of beam brackets on cast columns is that of hidden flaws and shrinkage cracks or strains, whose existence can rarely be discovered until too late, and which are especially liable to occur in or near the bracket, owing to the irregularities of surface and thickness at that point.

To avoid this danger as far as possible, abundance of metal should be used in the brackets, but rather in the way of large ribs than of excessive thickness, which, by irregular shrinkage, is apt to invite the danger it seeks to prevent. It will also be well to make all fillets around the bracket as large as can conveniently be done without interfering with the beam, as sharp angles are very apt to cause strains and cracks in cooling.

With all precautions, however, the cast bracket is an uncertain dependence for a heavy load, and where great weights have to be carried in this way and a wrought-iron column is for any reason undesirable probably the best thing to use is a wrought-iron key, as at A.

The illustration shows the upper ends of two of the columns of the large boiler house, called "Station B," of the New York Steam Company on Greenwich Street. Economy both of space and of cost rendered the use of cast columns desirable, but the excessive loads to be carried on the brackets and the disastrous consequences of explosions, etc., in case of failure were serious objections to the use of cast brackets.

The problem was finally solved by coring a hole through the column and introducing a wrought-iron bar or key A, 3 inches wide, 6 inches thick and 32 inches long, on the ends of which rested the upper chords B B of the main floor girders that carried the boilers. These columns were 20 feet long, 16½ inches outside diameter, and varied on the different floors from 1¼ to 1 inch in thickness. The girders were lattice, four feet deep, in pairs, and though not directly attached to the columns they were tied together by plates and hooked over the keys so that they could not get away.

The reduction of the section of the column caused by the hole for the key did no harm, as the total load above the bearing of the key was reduced in nearly the same proportion by what was taken off at that point. Brackets E E gave additional support to the key, which, however, was strong enough without them. The arrangement was simple and satisfactory, and while cast brackets might have answered all purposes, the keys gave an assured security that well paid for their slight additional expense. Even a cast-iron key similarly used would probably be more reliable than a cast bracket.

At F is shown the base of the column next above and the method of fitting the two together by turned and bored surfaces. It will be noted that the columns merely set one on top of the other, being steadied only by the beams. This is all well enough after the building is up, but during erection it will usually be found very convenient to have a flange connection between the columns on successive floors, so as to secure them from being accidentally knocked over while setting the girders or doing other work.]

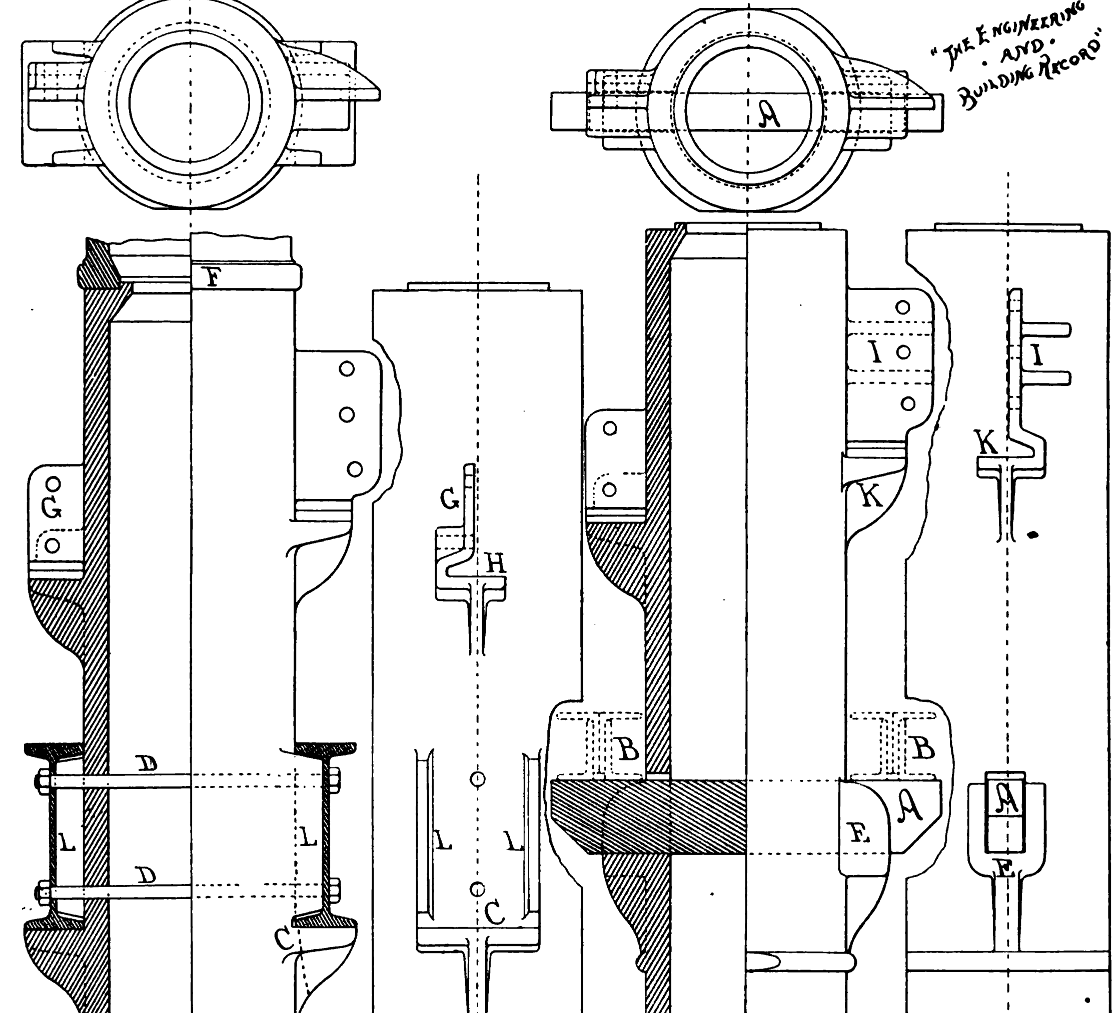
BEAM BRACKETS.



DOMESTIC PLUMBING HEATING LIGHTING & VENTILATION ENGINEERING

NEW YORK STEAM COMPANY TANK CONNECTIONS.

THERE are given herewith four views, showing the feed and blow connections with the boilers and the connections with the tank in the cellar of the building of the New York Steam Company. Into this tank all water of condensation is discharged and pumped back into the boilers together with a supplementary water supply from the city water mains.

The water of condensation enters through the 6-inch return main R, Figs. 5, 6 and 7. The feed pump suction connection to the tank is made at the lower part and is marked P. When, as is practically always the case, not a sufficient quantity of water of condensation is returned to the tank to supply the boilers, the deficiency is made up by admitting water from the city mains to the tank. This city water supply, which, at the station, is under a pressure of about 28 pounds per square inch, comes through the pipe D, from which a branch is taken by a tee. In this branch is a regulating valve V, controlled by a float in the tank through the intervention of the lever L (Fig 5). There being only a light pressure in the tank, the water under city pressure can readily enter. When the water level in the tank reaches the proper height the float closes the valve V and shuts off the street water supply. Should it become necessary, for any reason, to discontinue temporarily the use of the tank so that the feed cannot be taken from it, the valves E E (Fig. 5) are closed and the water from the street, coming through the pipe D, passes on through the prolongation D' direct to the pumps and thence into the main feed pipe F from which the smaller feed pipes *f* lead off to each boiler. The feed for each boiler is controlled by means of valves in these last mentioned pipes, worked from the boiler room by the rods *v*. The pipes G G, leading from the tank, connect with a glass water gauge. The pipe H is an exhaust pipe from the feed pumps, discharging into the tank, and the pipe K is an exhaust pipe from the tank to the roof, fitted with an automatic valve which opens and permits exhaust steam to escape to the roof when the pressure in the tank reaches a certain point. Should the cold water tank supply pipe, in which the regulating valve V is fitted, require shutting off to repair the valve or for some other reason, the tank may receive its auxiliary supply of cold water through the pipe J leading from the pumps. The blow and some of the feed connections are more clearly shown in Fig. 8; C is a check valve, while A is a special check and stop valve.

A large pump regulator, placed a short distance from the tank, controls the steam supply to the feed pumps so that the water supply to the feed mains always equals the demand. This regulator, briefly described, consists of a large vertical cylinder fitted with a properly guided piston. Steam at boiler pressure is admitted above the piston and the water discharge pipe from the pumps leads below it and passes out again at the other side of the regulator cylinder. All the feed water must thus pass through this cylinder. Should all the feed valves at the boilers be closed, the water, discharged by the pumps beneath the regulator piston, will increase the pressure until it rises above the steam pressure above the piston. Accordingly the latter will rise and through the intervention of a lever system will shut off the steam supply to the pumps. When the feed valves are again opened the water pressure will fall below the steam pressure, the regulator piston will descend, and the steam supply valve to the pumps will be opened. If only some of the boiler feed valves are closed while others remain open, the pump regulator will only partially shut of steam supply to the pumps, and these will run at reduced speed, the water supply in every case being regulated according to the quantity drawn off for the boilers.

It is proper to explain here that the feed connections to the boilers, as shown in Figs. 6 and 8, are not those in regular use, but are what may be called emergency connections. The feed pipes ordinarily employed run up in front of the boilers from the main feed pipes F and discharge into the steam drums. There are no special features in their arrangement, hence they are not shown in the illustrations.

Figure 5, it will no doubt be understood, represents a side view of one end of the tank with the piping; Fig. 6 is an end view, and Fig. 7 a top view.

SCHEMES are under consideration which will, if carried out, devote about 2,700 acres of land about London to public use for ever.

BOSTON PLUMBING LAW.

THE City Council of Boston, Mass., has recently amended the ordinances as follows :

SECTION 1. Sections 16 to 29, inclusive, of chapter 48 of the Revised Ordinances of 1890, are hereby amended to read as follows ·

REGULATIONS FOR PLUMBING.

SEC. 16. Every plumber, before doing any plumbing work in a building, shall have his name and place of business registered in the office of the Inspector of Buildings; shall, except in the case of repairs which do not involve any change in the location of a water fixture or trap or of a waste, drain or ventilating pipe, file in the office of said inspector, upon blanks to be provided for the purpose, a description of all work to be performed, and shall obtain from said inspector a permit to do such work; he shall give immediate notice to said inspector of any change of his place of business.

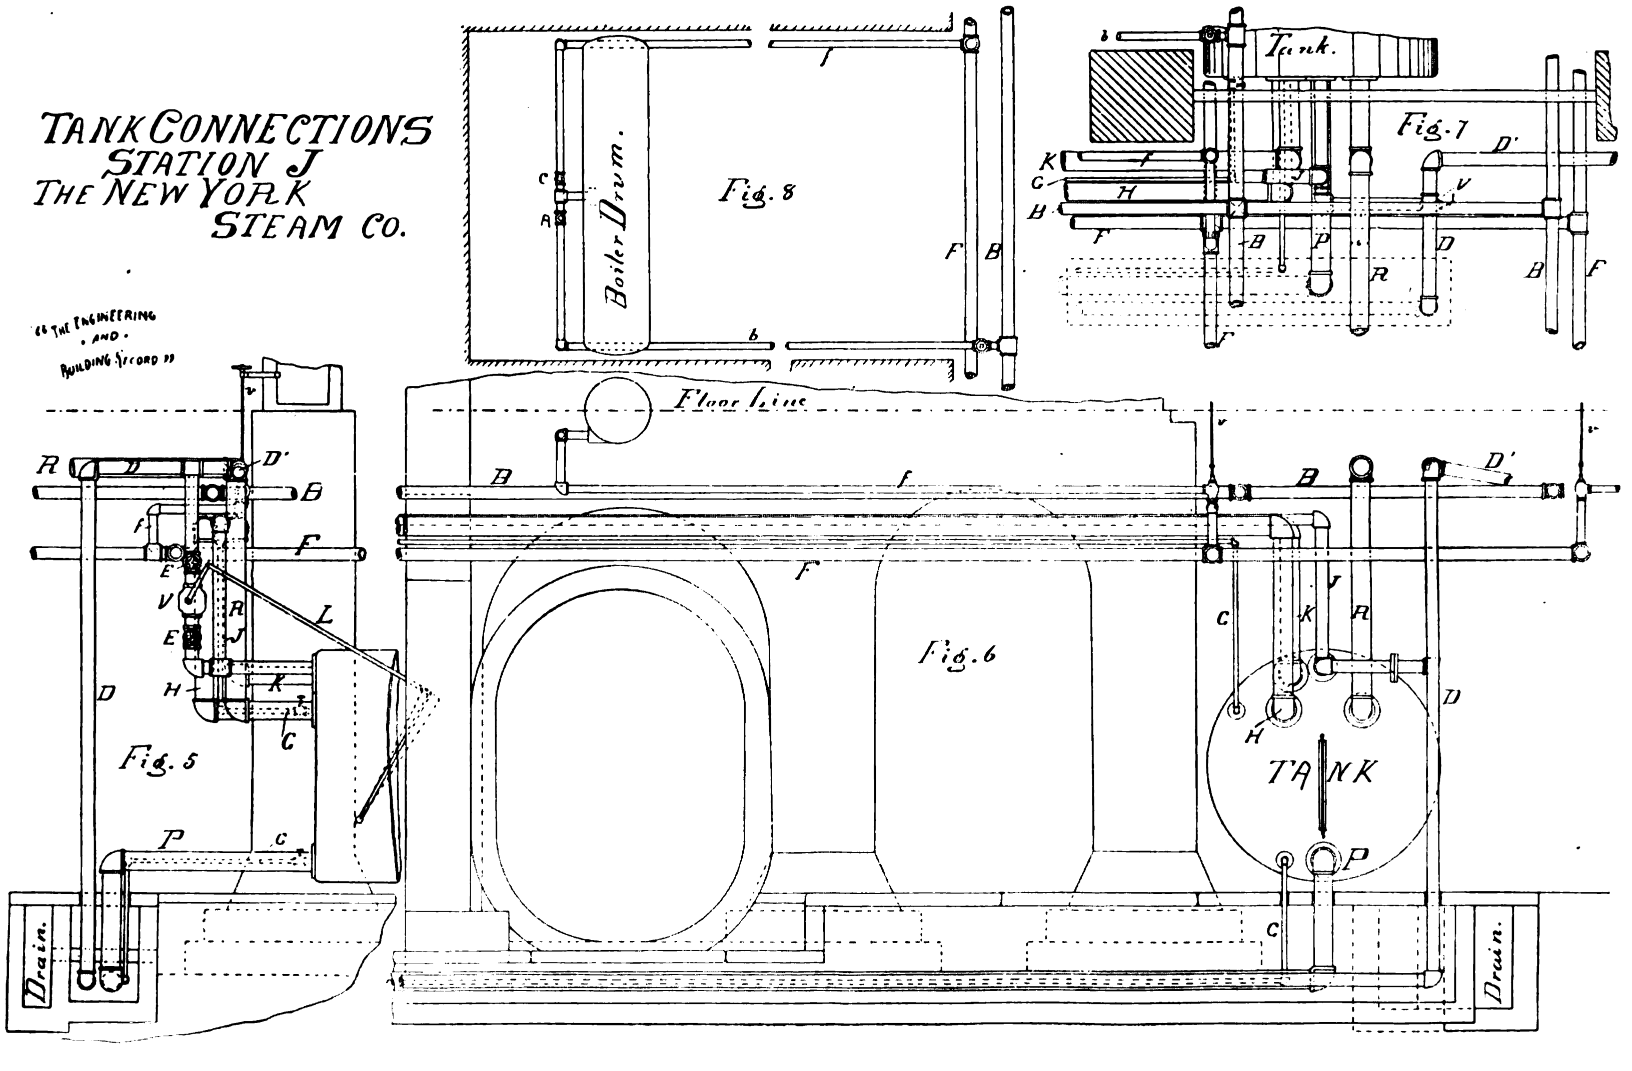
SEC. 17. Every building provided with water from the city or other water supply shall have a drain-pipe for the conveyance of waste water and sewage into the public sewer, or, if there is no sewer, into a sufficient and proper cesspool easily accessible for inspection and cleaning, and such drain-pipe shall not be used for the drain-pipe of any other building.

SEC. 18. Every such drain-pipe within the building, and for at least five feet outside the foundation walls thereof, shall be of what is known in the market as "extra heavy double thick cast-iron soil-pipe," not less than four inches in diameter, sound, free from holes and other defects; shall be laid in a trench, securely ironed to walls, or suspended by strong iron hangers; shall have a continuous fall towards the sewer, and shall, either outside or inside and near the foundation wall of the building, be supplied with a suitable trap having an accessible clean-out.

SEC. 19. The drain-pipe of every building hereafter erected, and of every building already erected in which an additional water-closet is hereafter placed, and of every building already erected in which a water-closet is moved from a place within the building to a room not having a window or other opening immediately to the air on the outside of the building, and within 12 feet of such window or opening, shall be of the same diameter throughout its entire length, and be carried above the roof of the building at least two feet.

SEC. 20. A separate and suitable trap shall be attached to every waste-pipe connecting a water fixture or rain-water leader with a drain-pipe; and such trap shall be placed as near as practicable to such fixture or leader, and no water fixture, trap, or pipe shall be connected with the drain-pipe except by means of a trap.

SEC. 21. Waste-pipes from safes under water-closets, urinals, or other fixtures, or from tanks or cisterns, or from refrigerators or other receptacles in which provisions are stored, if connected with the drain-pipe, shall be run to some place in open sight into an open tray connected by a suitable trap with the drain-pipe.



SEC. 22. Every waste-pipe from a kitchen sink of an eating-house, hotel, restaurant, or other public cooking establishment, shall be connected with a grease-trap placed as near as practicable to the sink, and easily accessible for cleaning.

SEC. 23. A ventilating pipe, of a size not less than the waste-pipe to which the trap is attached, continuously inclining upward from the top of the trap, and running as directly as practicable at least three feet above the roof of the building, shall be tightly attached to each trap. Every ventilating pipe shall be of what is known in the market as extra heavy double thick cast iron, or brass or lead, and the ventilating pipe for every water-closet shall be of not less than two inches in diameter when the ventilating pipe is less than 30 feet in length, and of not less than 3 inches in diameter when the ventilating pipe is more than 30 feet in length; no chimney flue shall be used as a ventilating pipe. Two or more ventilating pipes may be connected together, or may be connected with the drain-pipe above every waste-pipe entering the drain pipe.

SEC. 24. A tank or system shall be connected by a pipe not less than one inch in diameter with every water-closet or line of water-closets in a building, so that water therefrom will thoroughly flush the water-closets.

SEC. 25. All iron pipes before being put in place shall have been tested by the water or kerosene test, then coated inside and outside with coal tar pitch applied hot, or with paint, or with some other equivalent substance; connections of iron pipes shall be run with molten lead thoroughly calked; connections of iron with lead pipes shall be made with brass ferrules, thoroughly soldered to the lead, and the connection of the ferrules with the iron pipe run with molten lead thoroughly calked; changes in directions shall be made with curved or Y branches.

SEC. 26. Water pipes in places exposed to frost shall be securely cased and packed with mineral wool or other equally good substance.

SEC. 27. Plumbing work shall not be covered or be concealed from view until after the work has been examined by the said inspector; and he shall be notified by the plumber when the work is sufficiently advanced for inspection.

SEC. 28. Plumbing work shall not be used until the same is in good condition, as shown by the water test made by the plumber in the presence of the inspector.

SEC. 29. No steam exhaust pipe shall be connected with any ventilating, waste or other connecting pipe, nor with any drain-pipe inside of the trap of the drain-pipe placed near the foundation wall of the building.

PROHIBITIONS AND PENALTIES.

SECTION 1. Chapter 49 of the Revised Ordinances of 1890 is hereby amended by inserting between sections 25 and 26 the following sections.

SEC. 26. No person shall do any plumbing work in a building, or cover from view or use such work, in violation of the regulations for plumbing contained in chapter 48 of this ordinance.

SEC. 27. No person shall connect any steam exhaust pipe with any ventilating, waste, or drain pipe in a building, inside of the trap of the drain-pipe placed near the foundation wall of the building.

And said chapter is further amended by inserting between sections 36 and 37 the following section:

SEC. 37. No person shall place, or drop and suffer to remain in any street, any merchandize of any kind, or any gravel, sand, or other material, or any noxious, offensive, or refuse matter or substance.

Notes and Queries

on Domestic Engineering.

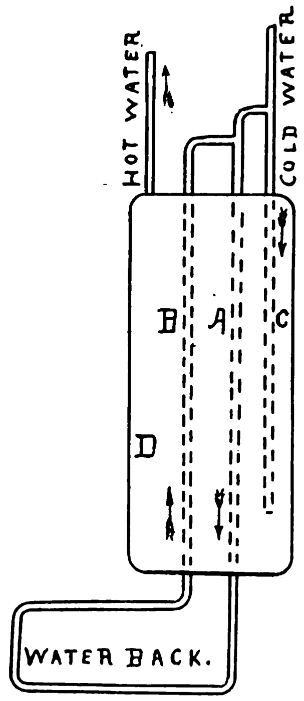
Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

HOT WATER BOILER WITH HOT WATER HEATING COIL.

A STAUNTON, VA., correspondent sends a sketch of a bath boiler, here reproduced, explaining that in that section of the country they have a very strong limestone water. What he wants to know is whether with this form of arrangement the stopping up of the water-back with lime will be prevented; also, whether the water in the boiler can be heated in as short a time as in the ordinary form of boiler; and, finally, whether the water in passing through A B will not find its way into the pipe C.

The principle of the boiler is the same as that utilized in many forms of water heaters now on the market, the pipes within the heaters, however, serving for the circulation of waste steam instead of hot water, as in the present case. These heaters, as our correspondent undoubtedly knows, all work more or less successfully. In the particular case under consideration the water heating capacity, or the rapidity with which the water in the boiler D will be heated by the circulation of hot water in the pipes A B, is simply a question of heating surface in the pipes A B and in that part forming the water-back. With sufficient surface, relatively, to the amount of water in the boiler D, we do not see why good results should not be reached. The tendency of hot water from the pipes A B to enter the pipe C is slight; not worth considering, in fact, unless the connection were of so very large a diameter as to admit of circulation within the pipe itself. The chance of this is remote. Some heat will go to the cold water in the inlet pipe by conduction, but this will be slight.

The theory in this case of the prevention of lime obstruction in the water-back obviously is that the water which is once admitted to the pipe system A B and the water-back extension practically remains there, unchanged in quality, except so far as that change is concerned which occurs after it is heated for the first time by circulation through the water-back. This first heating would have the effect of causing a separation of some of the scale-forming impurities held in solution, after which there would be no tendency to form a further deposit. The pipes A B and water-back would probably not be stopped up by this comparatively small amount of initial scaling, though, in the course of time, if the water contained in them be drawn off occasionally and fresh water let in from the cold water supply pipe, new deposits would be formed, which would ultimately, if this drawing off and refilling be repeated often enough, clog the pipes.



HOT WATER COIL FOR BOILER

The scale-forming matter in the water which is heated in the boiler D by the pipes A B would be deposited in the boiler itself, and not interfere with the working of the water-back.

THE PEPPERMINT TEST FOR PLUMBING.

CHARLES F. WINGATE, of New York, writes: "Your directions for making peppermint tests are incomplete. In my practice I try to use a large amount of very hot water—several gallons—poured down from the roof into soil and waste pipes, so as to heat them thoroughly. An ounce of oil is entirely inadequate. I never use less than three ounces and usually six or eight ounces of the best; the cheap adulterated oils are valueless. But the peppermint test is very uncertain in its results. The smoke test is far preferable."

[The amount of peppermint needed of course depends on the size of house and extent of drainage system. The reply we quoted contemplated a small country house. We also prefer the smoke test, but this cannot be applied without a special machine.]

THE prize offered by the *Cosmopolitan Magazine* for a plan for a public bath has been awarded to John G. Howard, of New York, and two meetings have been held looking to the erection of the structure in the city. It is proposed to have a public laundry, as well as baths for both sexes, and to charge small fees for the use of each. Among the men named as interested in the scheme are Bishop Potter, President Seth Low, of Columbia College; Cornelius Vanderbilt, Brayton Ives, Abram S. Hewitt, the Rev. Edward Everett Hale, Erastus Wiman, Joseph H. Choate, Col. John A. Cockerill, William Astor and Richard M. Hunt.

EDWARD SOUTHWICK PHILBRICK.

MR. PHILBRICK was a valued contributor to this journal from the time it was started to the day of his death, and readers will be glad to see a full biographical notice of him, prepared by his friends and associates. The following article was prepared by Albert H. Howland, Desmond FitzGerald and Walter Shepard, Committee of the Boston Society of Civil Engineers; read April 17, 1889, and published in the *Journal of the Association of Engineering Societies:*

Edward Southwick Philbrick, son of Samuel and Eliza (Southwick), was born November 20, 1827, and died February 13, 1889. He was descended from Quaker ancestry that had been native to the shores of Massachusetts Bay from near the date of the settlement of Boston. He was born in Boston, but except during early infancy his home was always in the adjacent town of Brookline. His father was a merchant in Boston, a director in several corporations, and for thirty years treasurer of the Massachusetts Anti-Slavery Society.

In 1843, after fitting for college at the Brookline High School, he entered the Sophomore class at Harvard College. Paternal consent to this step, however, was conditional upon his living at home, walking the three miles each way to and from college daily, and spending no time on the study of Greek. These requirements were strictly complied with, but the restriction as to Greek prevented his receiving the customary degree on the completion of his course; at a later date, however, in recognition of his merits in other directions, the degree was conferred as of the class of 1846, to which he belonged. In the list of its members are the names of Senator George F. Hoar, Dr. Calvin Ellis, Dr. Charles D. Homans, and Professors Francis J. Child, George M. Lane and Charles E. Norton.

In the summer of 1847, after spending a few months in the office of the late Samuel M. Felton, he began field work on the Rutland and Burlington Railroad, in Vermont, holding the position of assistant engineer on location and construction. Upon this work he was engaged some three years. Then going to Canandaigua, N. Y., he was employed in the construction of some branches of the Erie Railway. He held here the position of resident engineer of location and construction, and this work occupied another three years till near the end of 1853.

The decade that included these six years was marked by striking advances in the application of iron to bridge work. The great Conway and Britannia tubular bridges were built; the Victoria tubular bridge over the St. Lawrence at Montreal was begun; suspension bridges were built over the Ohio at Wheeling and the Niagara at Lewiston; and the great railroad suspension bridge at Niagara Falls was finished. Several of these structures were near the territory within which Mr. Philbrick was engaged in railroad building, and the subject of iron bridge construction so strongly engaged his attention that he soon took an opportunity to extend his knowledge of such structures as well as of public works in general.

A few months after he had finished work in Western New York he sailed for Europe, and remained abroad a year and a half. Several months were spent at Paris in professional studies. Then much of the time, with knapsack on his back, he traveled through Great Britain, France, Belgium, Austria, Italy and Turkey. Passing beyond Europe he extended his travels to Egypt and Syria, spending in these countries the last six months of his stay abroad. Mr. Philbrick was a close observer, and being, furthermore, the possessor of a retentive memory, he gathered during these travels a store of information that was a frequent source of surprise to those with whom he conversed, minute details even not escaping him, especially such as had a professional bearing.

In the summer of 1855 he returned home and soon afterwards entered the employ of the Boston and Worcester Railroad as Assistant Superintendent and Engineer. For five or six years he was engaged in improving the location of the road and rebuilding some of its structures. A bridge that he designed and built during this period, namely, the "Arsenal Bridge," in Brighton, should be mentioned in this connection, not on account of its size (for it is merely a plate girder of 87 feet span in the clear) but as an instance of his early preference for riveted work, and as evidence of the soundness of his judgment in selecting at that day a type of structure for spans approaching even 100 feet, that after a quarter of a century's experience has come to be pretty generally approved as the most suitable. This was built in 1860. In the early part of the next year Mr. Philbrick again spent several months in Europe.

Near the beginning of 1862, after Port Royal had been captured by the Union forces, and had become the refuge of the negroes of the neighboring country, true to his inherited anti-slavery principles and his own convictions, Mr. Philbrick undertook the organization of labor on a dozen or more abandoned plantations in that and the neighboring islands, including the education and training of the freedmen as citizens. Many volunteers from this vicinity accompanied and assisted him in the work, which was carried on for two years under the direction of the United States Treasury Department on government account. Subsequently the Government sold the plantations for taxes, and the work was continued by a corporation formed for that purpose, which was successful commercially as well as in respect to its main purpose.

After the war closed Mr. Philbrick was employed upon some town improvements in Brookline, and connected with some manufacturing enterprises. In 1869 he was appointed by the Governor of Massachusetts Inspecting Engineer of the Boston, Hartford & Erie Railroad, to which the State had made a loan of $3,000,000.

About this time the Boston and Albany Railroad was formed by the consolidation of the Boston and Worcester and the Western railroads. The traffic of the road increased to such an extent that the work of rebuilding its bridges in iron was decided upon and Mr. Philbrick was appointed Consulting Engineer and had charge of it. A large number of bridges were built, mostly between Worcester and Albany. The type he adopted was the riveted lattice, or for small spans the plate girder. The most notable among these bridges was that over the Connecticut at Springfield, and it occasioned a good deal of controversy as to the comparative merits of riveted and pin-connected trusses. Without entering into the details of the question (for the controversy is by no means ended) it seems proper to say that Mr. Philbrick's judgment is supported by the practice of some of the largest and best managed roads and that even pin-connected bridges in recent years have been made to conform in some features to the riveted type. Mr. Philbrick's preference for riveted connections did not extend to very large spans. Other works on the Boston and Albany Railroad constructed under his charge were the large Union Station at Worcester, and the grain elevators in Boston, that at East Boston being notable on account of the difficulties encountered in securing good foundations.

Near the close of 1868 the State of Massachusetts contracted for the completion of Hoosac Tunnel. The Troy and Greenfield Railroad Company had previously received State aid to the amount of several million dollars to build the tunnel and connecting railroad, but after 20 years' efforts much the larger part of the tunnel remained unfinished and the State had come into possession. A year or two after the contract was made Mr. Philbrick was consulted upon some questions that arose as to alignment and quantities, and was soon afterwards appointed Consulting Engineer to the Governor and Council for this work, and held that position till the tunnel was opened. The amount of this contract was over $4,500,000. The accuracy with which the headings met was remarkable; at two miles from the east portal, where the heading from the central shaft was met, the deviation was only $\frac{5}{16}$ of an inch in line and 1¼ inches in level. Besides the tunnel proper there was a large amount of work in improving the line and building iron bridges on the connecting road, of which Mr. Philbrick was engineer.

The improvement of the flats at South Boston was also carried out under Mr. Philbrick's charge, and is a work of considerable local importance. The State contracted for building the sea walls and filling a portion of the flats in the latter part of 1873. A large area adjacent was owned by the Boston & Albany Railroad, and a contract was made for filling this at the same time. Mr. Philbrick had charge of this also. The territory thus made available now forms the terminal grounds of the New York & New England Railroad, provided with extensive freight sheds, grain elevator and wharves and docks for ocean steamers, distant only about a half mile from the post-office. These sea walls are notable for their substantial construction, and the Harbor Commissioners say, in one of their reports, that "no work, to their knowledge, has been undertaken in any harbor of our country superior in its design or workmanship to the plan and execution of the heavy sea wall, so far as it has progressed."

When the growth of the town of Brookline necessitated a public water supply the construction of the works was intrusted to Mr. Philbrick. The supply is taken from a filtering gallery near Charles River at a point a few miles from the town. These works were constructed during 1874–5 at a cost of half a million of dollars.

As a sanitary engineer, Mr. Philbrick had a wide reputation and was esteemed an eminent authority. The building, ownership and care of nearly a score of houses gave him opportunity for long continued experiment and a practical knowledge of the actual conditions to be met. The results of his experience in this branch of engineering were given to the public in a book on "American Sanitary Engineering," in pamphlets on "Defects in House Drainage and Their Remedies," and on "Disposal of Sewage in Suburban Residences," and in contributions to periodicals and discussions at society meetings. The publications form an interesting and important part of the sanitary branch of engineering literature. They have been extensively used in the practice of engineers and are often referred to as standard works on the subject.

Included in his professional practice were consultations as to the foundations of Trinity Church and the new public library building in Boston; service on commissions to award damages for diversion of water by the city of Worcester from Blackstone Valley and by the city of Cambridge from Stony Brook, and to investigate the causes and management of the Great Fire in Boston; reports on sewerage in several neighboring towns; building of highway and railway bridges over the Merrimac at Haverhill, and others of less note. New England is the field where most of his professional work has been done. Domestic ties and the care of a large property tended to prevent him from seeking other fields.

His membership in our Society dates from June 8, 1874, and in the American Society of Civil Engineers from May 6, 1876. The transactions of the latter contain several of his papers and discussions, among which is a paper on the South Boston Flats improvements.

Marked characteristics of Mr. Philbrick were a directness, simplicity and candor that won the confidence of those with whom he dealt. These qualities with his practical knowledge and varied experience caused his services to be sought for where the construction of expensive works demanded unquestioned fidelity and ability. With contractors he was sometimes considered rather strict, but he was fair-minded and considerate and ready to yield if he found himself in error. He was a man of varied interests; the newest book and the latest achievement of science received his attention.

Mr. Philbrick was free from all ostentation, and while professional duties and the care of his property and of trust funds engrossed much of his time, there were many enterprises benevolent in nature or aiming to promote the general welfare which received his active and devoted support. Well known among these is the Massachusetts Institute of Technology, of whose corporation he had for many years been an active member. In benevolent efforts his aim was to avert as well as to relieve misfortune and suffering.

As a citizen he was public-spirited, independent in politics, and deeply interested in whatever tends to promote good and honest government, often devoting time and money to this end though seeking for himself no conspicuous part.

In religious belief he was a Unitarian and served as treasurer of the First Unitarian Church in Brookline for many years.

On the 16th of September, 1857, he married Miss Helen M., daughter of the late Alfred Winsor, of Brookline, who, with his mother, now 96 years of age, are the survivors of his household.

The works of the engineer often receive but little of the popular appreciation that their merits deserve. They may be located in remote and unfrequented places, or buried where the light of day never reaches them; often they are so unobtrusive that they seem to be almost a part of nature's own handiwork. Hence there is a peculiar satisfaction, when an occasion like this makes it fitting to recount them, in considering what a monument it is that he leaves behind him in the highways that bring to the people the products of a continent, the structures over which millions pass in safety, the warehouses where the food of the nations is stored, the grounds where the products of the world are distributed, the appliances that secure health to our homes. Such works bear witness to his skillful designing, fidelity in execution, patient toil in overcoming obstacles that seem almost insurmountable, foresight in providing for emergencies, correctness in reasoning, and an integrity that will not deviate from an honest course to secure in a day the profits of a life-time. Such qualities will be freely ascribed to Mr. Philbrick; and the warm personal esteem of those who knew him well will ever cause them to hold him in grateful remembrance.

BERLIN TELEPHONES.

In Berlin the erection and maintenance of telegraph and telephone wires is placed under charge of a special department, with what is called a Councillor of the Post Office at the head. From some statistics printed in *Kuhlow's* it appears that nearly 1,000 men are employed in laying and repairing the telephones in this city. In addition, there are about 600 persons employed in the switch stations. The telephone was opened with 50 subscribers. The number of speaking places now exceeds 13,000, and the new applications show no sign of diminishing. Thirty-six officials are at present employed on the erection of overhead telephones. Last year there were eight other officials from other postal districts temporarily examining the wires here. The 28 erecting sections employ 15 wire superintendents, 60 men for preparatory work and 239 permanent and temporary workmen and assistants. There are, further, 45 slaters, 38 tinsmiths and 44 slaters' laborers who are provided by a private contractor in accordance with contract. There are, therefore, 477 persons employed on the overhead telephones, inclusive of the 36 officials. In the fiscal year 1889–90 they erected 34,390 meters of lines with wooden posts and 101,287 meters with iron posts and 7,491,536 meters of wire, or one-fifth the circumference of the earth and three-fifths its diameter. Further, 3,306 speaking places were established, and 1,427 transferred from one place to another, most work being done between the 1st of April and the 1st of October. On an average between 15 and 16 new speaking places were established on every working day of the year.

CAPACITIES OF BLOWERS AND EXHAUST FANS.

The following tables show the guaranteed air supply and air removal of leading forms of blowers and exhaust fans. They are taken from a paper on "The Ventilation of Buildings," by A. R. Wolff, published in the April number of *The Stevens Indicator*.

The figures given, as Mr. Wolff explains, are often exceeded in practice, especially when the blowers and fans are driven at higher speeds than stated. The ratings, particularly of the blowers, are below those generally given in the manufacturers' catalogues.

TABLE I.

Showing Quantity of Air Supplied to Buildings by Blowers of Various Sizes.

Diameter of Wheel (in Feet.)	Ordinary Number of Revolutions per Minute.	Horse-Power to Drive Blower.	Guaranteed Capacity in Cubic Feet per Minute Against a Pressure of One Ounce per Square Inch,
4	350	6.	10 635
5	325	9.4	17 000
6	275	13.5	29.018
7	250	18.4	42,700
8	200	24	46,000
9	175	29	56,800
10	160	35.5	70 340
12	130	49.5	102,000
14	110	66	139,000
15	100	77	160,000

Of course if the resistance exceeds the pressure of one ounce per square inch, of above table, the capacity of the blower will be correspondingly decreased, or power increased, and due allowance for this must be made when the distributing ducts are small, of excessive length, and contain many contractions and bends.

TABLE II.

Showing Quantity of Air Moved by an Approved Form of Exhaust Fan.

Diameter of Wheel in Feet.	Ordinary. Number of Revolutions per Minute.	Horse-Power to Drive Exhaust Fan.	Guaranteed Capacity in Cubic Feet per Minute, the Fan Discharging Directly from Room into Atmosphere.
2.0	600	0.50	5,000
2.5	550	0.75	8,000
3.0	500	1.00	12 000
3.5	500	2.50	20,000
4.0	475	3.50	28,000
5.0	350	4.50	35.000
6.0	300	7.00	50,000
7.0	250	9.00	80,000

It should be noted that the capacity of exhaust fans here stated, and the horse-power to drive them, are for free exhaust from room into atmosphere, and that the capacity decreases and the horse-power increases materially as the resistance, resulting from lengths, smallness, and bends of ducts enters as a factor. The difference in pressure of Tables I. and II. is the main cause of variation in the respective records. The fan referred to in Table II. could not be used with as high a resistance as one ounce per square inch, the rated resistance of the blowers in Table I.

BOOK NOTICES.

THE DISPOSAL OF HOUSEHOLD WASTES. By William Paul Gerhard, C. E.; pp. 195; published by D. Van Nostrand Co.; price, 50 cents.

Mr. Gerhard's little book is one of Van Nostrand's well-known "Science Series," and in it the author discusses at some length the important question of how to dispose of the waste matters of the household in the safest, least disagreeable, and most efficient and economical manner. The treatment of the subject is chiefly from the householders' point of view, and will accordingly commend itself to the average reader. The subject itself is of current interest and importance, and we have no doubt, therefore, that the little work will prove a most welcome source of information to a large number of people. An appendix gives three interesting sets of specifications—one for laying house drains and pipe sewers; another for building a tight cesspool; and, finally, one for a sub-surface irrigation system for a country house. Suggestions for a sanitary code fill up the concluding pages.

TRADE PUBLICATIONS.

OFFICIAL REPORTS OF VARIOUS DUTY TRIALS OF THE GASKILL PUMPING ENGINE.

The above volume, dated 1890, has just been issued by the Holly Manufacturing Company, of Lockport, N. Y. It contains the reports of 27 different duty trials of Gaskill pumping engines made since 1882, at various cities, and will be found full of matter of interest and value to engineers generally. Many of the reports go into the details of the methods of testing followed, representing desirable examples of the way such work should be carried out. The book embraces 224 pages and is profusely illustrated.

STEWART CERAMIC COMPANY.

We have received from the Stewart Ceramic Company, of 312 Pearl Street, New York, price-list and illustrated catalogue describing the various kinds of wash-tubs manufactured by them, together with directions for finishing and setting same.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

CONTRACTING INTELLIGENCE

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." *Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.*

Persons who make any use of the information they find in these columns we trust will not omit to mention THE ENGINEERING & BUILDING RECORD as the source

For works for which proposals are requested see also the "Proposal Columns," pages i-ii-47.

WATER.

For Additional Water Items see Proposal Columns.

NILES, MICH.—Recorder W. Landon writes: "Nothing has been done towards water-works as yet."

GENOA, ILL.—City Clerk D. W. Hartman writes: "Our Town Council have called a special election for June 21, to take an expression of the people as to whether they want water-works or not. The system contemplated is the Holly system, with tank system of reservoir. I think the vote will be for, and that the work will be started in the near future."

CINCINNATI, O.—It is now proposed to connect the Covington and Newport, Ky., water service with the system belonging to this city, by laying pipes across the bridges. It is said that the supply of these adjacent places is more than sufficient for their own use, and that at least 15,000,000 gallons daily can be furnished to Cincinnati. This remedy is only proposed until Cincinnati can secure her own permanent and sufficient supply.

SOUTHAMPTON, N. Y.—The movement for establishing a system of water-works in this village, mentioned in a recent issue of this paper, has assumed definite shape, and a company is about to be organized for the purpose of building a plant, the estimated cost of which is $35,000. The matter is being managed by the summer residents of the place, headed by Dr. G. Thomas, who can furnish further particulars.

BROOKLYN, N. Y.—At a meeting of the Board of Aldermen, held June 16, a resolution was submitted asking that the Commissioners of Public Works be given authority to construct a water stand-pipe upon the grounds of the Prospect Heights reservoir, the cost not to exceed $65,000, and that bonds for the amount necessary be issued. The resolution was referred to the Committee on Water and Drainage.

FREEHOLD, N. J.—This place has voted to own the proposed water-works, consequently the system will be established by the city.

VERNON, CONN.—This town has voted to build a dam and lay a 4-inch water-main for a water supply for the almshouse.

CHICAGO, ILL.—The Chicago High Water Pressure Company has been incorporated in this city to construct and operate water-works. Capital stock, $5,000,000. W. C. Baine can furnish information.

NEW BRITAIN, CONN.—The Water Commissioners are having plans made for new mains.

JACKSON, MICH.—Efforts are being made to procure a suitable water supply for this place.

BETHEL, ME.—The taxpayers of this place have organized and are making efforts towards securing a system of water-works.

OWOSSO, MICH.—The City Clerk at this place writes: "This city owns its own water-works and has just voted $20,000 for additional improvements for same. Four miles of additional pipe will be laid, 18 hydrants, a new supply of water developed and a reservoir well 36 feet in diameter are among the contemplated improvements. W. R. Coates, of Kalamazoo, Mich., is the engineer."

SAVANNAH, GA.—The City Council, at an adjourned meeting June 11, authorized the committee on water to build independent water-works on the Springfield plantation, at an approximate cost of $250,000, and to put down two more wells on the present water-works tract for immediate relief, to obviate the necessity of using river water.

SPRINGFIELD, MASS.—The report of the Water Commissioners to the City Government, submitted June 16, which was unanimously accepted, has, it is said, solved the question of obtaining a pure water supply for this city. The report calls for an appropriation of $100,000, to purchase water rights and privileges and pay land damages to bring 7,000,000 minimum and 25,000,000 maximum gallons of pure water per day, through 1,700 feet of 53-inch wrought iron pipe and three miles additional canal, to a 10-acre reservoir at the head of the Ludlow structure, which is to be fed principally by brooks and seven streams. The plan also contemplates a waste gate and sluices for drawing down dry the Ludlow reservoir when the independent system is perfected, and the cleansing of its bed by fresh water slushing and other methods. There is said to be no doubt that the appropriation asked for will be voted at the next meeting of the City Government, and the work immediately entered upon, the Legislature having already granted the privilege to the city to remedy itself in this matter.

SALT LAKE CITY.—An extensive system of water-works is to be built here, contemplating an expenditure of about $1,000,000.

BURRELL, PA.—The Burrell Water Company is to establish a plant at this place. For particulars address John D. Boyle, as above.

LAKE GENEVA, WIS.—A plant is to be established at this place by the Lake Geneva Water and Light Company. The proposed expenditure is $40,000. James E. Heg can furnish particulars.

SIOUX CITY, IOWA.—It is reported that the water supply of this city is inadequate and that steps are to be taken at once towards increasing it or establishing a new system. Superintendent of Water-Works Sullivan can furnish details.

HACKENSACK, N. J.—The local water company is preparing to extend its mains to Maywood.

PARNASSUS, PA.—This place is to have a system of water-works. For details address Joseph P. Chappeu, as above.

COHOES, N. Y.—At a meeting of the Common Council, held June 17, the City Chamberlain was authorized to sell on July 7, bonds in the sum of $25,000, for the purpose of raising money to defray the expense of extending the water mains and making necessary repairs to the water-works plant. Mayor Garside can give details.

MADISON, N. J.—At the election held here June 16, the measure to appropriate the sum of $75,000 for water and light was carried.

FLEETWOOD, PA.—City Clerk J. K. Merkel writes: "It has been decided to get water in our town, but when and how is not decided yet. Might be able to inform you later."

SPRING CITY, TENN.—H. T. Price, Recorder writes: "The franchise has been granted for water-works by the Councilmen of Spring City, but I am unable to inform you when work will commence. Hon. H. T. Wilson, General Manager of the Anglo-American Association can, perhaps, give the desired information."

WATER-WORKS.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: St. Paul, Minn; Binghamton, N. Y.; Columbus, O.; Montreal, Can.; East Liverpool, O.; Winchester, Mass.; Mansfield, O.; Providence, R. I.; Ottawa, Ont., Brooklyn Village, O.; Des Moines, Iowa; Glenville, O.; Fargo, Dak.; St. Louis, Mo.; Ogden, Utah; Galesburg, Ill.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

WILMINGTON, DEL.—Additional sewers have been ordered by the city officials.

NEW ROCHELLE, N. Y.—The following bids for the construction of sewers and drains were received by Horace Crosby, civil engineer, June 14:

BIDDERS.	15-inch Pipe, Lineal Feet.	12-inch Pipe, Lineal Feet.	10-inch Pipe, Lineal Feet.	8-inch Pipe, Lineal Feet.	6-inch Pipe, Lineal Feet.	5-inch house connections, Lineal Feet.	Y's, each.	Rock, Cubic Yard.	Concrete, Cubic Yard.	Broken Stone, Cubic Yard.	Manholes, each.	Flush Tanks, each.	Lamp Holes, each.	Other Items.	Total.
William F. Croft, New Rochelle	$1.25	$1.15	$1.50	$1.03	$0.83	$0.88½	$1.00	$3.17	$6.00	$1.00	$40	$65	$15	$2,208.00	$46,237.40
Molloy Bros., New Rochelle	1.40	1.21	0.91	0.75	0.65	0.57	.30	3.00	3.75	.90	40	75	12	1,664.24	39,744.58
Van Vranken & Duell, Schenectady, N. Y.	1.02	0.98	1.32	0.82	0.53	0.43	.41	2.47	5.00	2.00	45	60	8	2,904.80	38,073.28

* Informal; withdrawn.

Contract awarded to Malloy Bros., June 18.

OGDEN, UTAH.—T. A. Perkins, City Engineer, writes: "Time for bids on sewer pipe and cement is extended to June 30." See our Proposal Columns.

ST. PAUL, MINN.—Kirkland & Starkey have been awarded the contract by the Board of Public Works for the construction of the Arlington Hills sewer system, at $53,243. The bids were as follows: Kirkland & Starkey, $53,245; William J. Preston, $58,000; Patrick Doherty, $62,191; Walter C. Doherty, $62,473; Stockton & Lindquist, $66,000; James Forrestal, $66,500; Thornton & Shaw, $71,900.

MITCHELL, S DAK.—The City Council has formally resolved to construct a Main Street sewer and sink a second artesian well.

BINGHAMTON, N. Y.—The following proposals for the construction of the Trout Brook and Trout Street sewer have been opened by the committee: Thomas Craig, Trenton, N. J., $21,000; E. A. Matthews, Binghamton, $17,400; Geo. W. Stow, Binghamton, $17,840. No award has been made.

GREEN BAY, WIS.—The officials of this city are discussing the question of establishing a system of sewerage. Mayor Elmore of this city and W. F. Goodhue, C. E., of Milwaukee, Wis., have discussed the matter, and it is probable the important steps will soon be taken. The Mayor can furnish information.

LA SALLE, ILL.—Work will soon be commenced on system of sewerage for this city, designed by Chester B. Davis, of Chicago, Ill. About three miles of 10, 18 and 24 and 36 inch sewers will be built this summer.

PHILADELPHIA, PA.—The Sewer Committee has approved the report of the subcommittee on main sewers, to which was referred the matter of the proposed expenditure of $240,000 appropriated for the construction of main sewers.

PETOSKEY, MICH.—Village Clerk A. C. Huntley writes: "A system of sewerage for this village is in contemplation, and survey made by Prof. C. E. Green, of Ann Arbor, Mich., who is preparing profiles, etc., and probable expense. The system is not an absolute certainty this season, but it is quite probable that the matter will be pushed through this season."

HOLLEY, N. Y.—City Clerk W. S. Housel writes: "A numerously signed petition of property owners, for sewers on certain streets, was presented to the Board of Sewer Comsioners of this village on June 13. The Board has appointed a meeting to be held July 1 to hear persons for and against the construction of such sewers, in accordance with the map and plan of a system of sewerage for this village, as approved by the State Board of Health. The outlook for sewers seems favorable."

ELGIN, ILL.—Numerous sewer extensions are to be made at this place. Address Alderman Brydges, as above.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

WINDSOR LOCKS, CONN.—It is reported that the New York, New Haven and Hartford Railroad Company contemplates the building of a bridge across the Connecticut River above this place.

JEFFERSON, TEX.—The plans for a number of bridges to be erected in this county are about completed, and proposals for their erection will soon be wanted. For further information address the Marion County Commissioners, at this place.

PUEBLO, COL.—An iron bridge, to cost $10,000, is to be erected at this place.

QUINCY, MASS.—Mayor Porter has petitioned the County Commissioners to enlarge the overhead bridge and approaches over the Old Colony Railroad at Hancock Street, this place.

SIOUX CITY, IOWA.—The Iowa Railroad Commission has decided to accede to the prayers of the city officials in the matter of placing a viaduct over the railroad crossings on lower Fourth Street, and the structure will be erected at once. Mayor Palmer, of this city, can furnish details.

AUSTIN, TEX.—The Hardeman-Willbarger Bridge Company has been incorporated to build a bridge across Red River, at Austin. Capital stock, $50,000.

SHELBURNE FALLS, MASS.—The following bids for the construction of an iron bridge over the Deerfield River at this place from plans and specifications by Edward S. Shaw, Consulting Engineer, of Boston, were received by the Bridge Committee of the towns of Shelburne and Buckland, June 12, and the contract was awarded to the Vermont Construction Co: Vermont Construction Co., St. Albans, Vt., $14,999; Penn Bridge Co., Beaver Falls, Pa., $16,200; Boston Bridge Works, Mass., $16,202; Rochester Bridge Works, Rochester, N. Y., $16,369; King Bridge Co., Cleveland, O., $16,610; Groton Bridge Co., Groton, N. Y., $16,750; Berlin Bridge Co., East Berlin, Conn., $17,290; Hilton Bridge Co., Albany, N. Y., $17,500; Canton Bridge Co., Canton, O., $18,000; Pittsburg Bridge Co., Pittsburg, Pa., $18,326; Wallis Iron Works, Jersey City, N. J., $20,800; New Jersey Steel and Iron Co., Trenton, N. J., $22,067.

RIVERTON, VA.—Town Clerk J. W. Morgan writes: "S. S. Turner, Esq., of Front Royal, Va., is President of a company which proposes bridging the south branch of the Shenandoah River at this place immediately."

NEW HAVEN, CONN.—It has been voted to appropriate the sum of $45.000 for the purpose of erecting a bridge over the Housatonic River, at Birmingham, Conn.

FRONT ROYAL, VA.—G. W. Cone writes from this place as follows: "The Front Royal and Riverton Improvement Company propose to build at once a 300-foot iron road bridge across the Shenandoah River at Riverton, Va. Information may be had by addressing the Vice-President, Geo. Wm. Cone, at Riverton, Va."

TRENTON, N. J.—The following bids for the construction of an iron bridge were received by Symmes B. Hutchinson, County Solicitor, June 14: New Jersey Steel and Iron Co., Trenton, N, J., $1,435; Milliken Bros., 55 Liberty Street, New York, $1,560; King Bridge Co., $1,520; Dean & Westbrook, $1,510; Variety Iron Works, Cleveland, O., $1,700; Finley & Lachicotte, York, Pa., $1,780; Groton Bridge Co., Groton, N. Y., $1,780; Berlin Bridge Co., East Berlin, Conn., $1,575.

MERIDEN, CONN.—There is a project here to bridge the tracks at Cooper Street. Address Mayor Paige for details.

BLOOMFIELD, N. J.—Plans for a bridge over the river at James Street are being prepared by County Engineer Owen.

DRESDEN, O.—The Smith Bridge Company, of Toledo, O., has been awarded the contract for the superstructure of a bridge over Wakatomika Creek, at this place, for $36.20 per lineal foot. Length of span, 123 feet C, to C of end pins. Steel truss and I beams for floor joists, floor 3-inch oak plank. Capacity, 2,000 pounds per lineal foot. Roadway, 18 feet.

KNOXVILLE, TENN.—Reports say that extensive repairs will be made to the bridge over Gay Street. The Chamber of Commerce is interested.

ASHEVILLE, N. C.—An iron bridge is to be built here by the Asheville Improvement and Construction Company. W. W. Barnard, the Secretary, can furnish particulars.

LITTLE ROCK, ARK.—A location for the proposed bridge, to be erected between Broadway and Main Street, has been decided on by the Commissioners.

NEBRASKA CITY, NEB.—A special meeting has been called by the County Commissioners and the City Council to vote July 8 on the proposition to issue $100,000 in bonds to the Nebraska City Highway Bridge Company to aid in building a wagon bridge across the Missouri River at this place.

GLASGOW, VA.—It is said that the Rockbridge Company, of this place, is interested in a movement to place a bridge over the North River, between this place and East Glasgow.

NEW ALBANY, IND.—A bridge is to be erected over Knob Creek, by the County Commissioners.

BRIDGES.—See our Proposal Columns for information regarding bridge construction at the following places: Dalton, Ga.; Mt. Vernon, O.; Columbus, O.; Albany, N. Y.; Salinas City, Cal; Foreman, N. D; Mitchell, Dak.; Pembina, N. D.; Eureka, Cal.; Alder Point, Cal.; Evansville, Ind.; Duluth, Minn.

NEW DEPOTS.

SPOKANE FALLS, WASH.—The Northern Pacific will soon erect a new depot at this place.

BENWOOD, W. VA.—Extensive shops and sheds will be erected here by the Baltimore and Ohio Railroad Company.

ELLENSBURG, WASH.—New repair shops are to be erected at this place by the Northern Pacific Railway.

RAILROADS, CANALS, ETC.

CINCINNATI, O.—George Hornung, engineer in charge, reports that the Mt. Auburn Electric Road is to be extended, and the plant is to be increased by 2-80,000 Watt. generators, 2-160 horse power engines and 2 boilers. They are ready to receive bids on engines and boilers. Address as above.

EL PASO, TEX.—Railroad.—The contract for grading, bridging, track laying, and the material for the first 100 miles of the Pecos Valley Railroad, from Pecos City, Tex., to Eddy, N. M., has been let to W. C. Bradbury & Co., of Denver. The work is estimated to cost $1,000,000.

STREET-WORK AND PAVING.

PATERSON, N. J.—The Paterson Plank Road Committee of the Bergen County Board of Freeholders decided, June 17, to macadamize the plank road through the village of Carlstadt.

PHILADELPHIA, PA.—The Council's Highway Committee has authorized the expenditure of the sum of $255,000 for paving certain streets in this city.

AMSTERDAM, N. Y.—All the proposals for furnishing 175,000 fire-clay paving brick were rejected by T. E. Crane, the engineer, June 10, as they exceeded the maximum figure named. New bids will soon be wanted.

WILMINGTON, DEL.—Considerable paving to be done at this place.

ZANESVILLE, O.—T. B. Townsend & Co. have been awarded the contract to pave 3d, 4th, 5th, Market and Marietta streets with vitrified brick at $1.29 per square yard, total cost.

GAS AND ELECTRIC-LIGHTING.

CUERO, TEX.—This place is to establish an electric lighting plant.

CHEHALIS, WASH.—This place wants electric lights.

KEESEVILLE, N. Y.—An electric lighting plant is soon to be established at this place. Address the Town Clerk for details.

AKRON, O.—The local electric light company will make important extensions to its plant.

WARE, MASS.—The Ware Electric Light Company will make improvements to its plant.

STOCKTON, CAL.—The Stockton Electric Company has been formed here. Cash capital, $1,000,000. F. E. Birge is at its head.

HUNTINGTON, ARK.—An electric light plant, 750 lights capacity, is to be established at this place by the Huntington Cotton Company.

MORRILLTON, ARK.—The taxpayers of this place have decided to establish an electric lighting plant.

HOQUIAM, WIS.—Reports say that the Aberdeen and Hoquiam Electric Railway Company is to establish an electric light plant at this place in connection with its street railway.

GRAND RAPIDS, MICH.—The City Clerk has been authorized to advertise for proposals for lighting the city for the ensuing year.

OWEGO, N. Y.—This place is to be lighted by electricity.

SUMMIT, N. J.—An electric light plant is proposed for this place. Address A. A. Smalley for information.

NEW YORK CITY.—The Commissioners of the State Reservation, at Niagara, have decided to light the State Park by electricity.

SCRANTON, PA.—The Wightman Electric Manufacturing Company has been incorporated here, with a capital stock of $30,000.

BURRELL, PA.—This place is to be lighted by gas.

LEBANON, N. H.—This place has voted for electricity as an illuminating power.

RAPID CITY, S. DAK.—A gas company is to be established at this place. For particulars address the Hon. W. T. Coade, of Chicago, Ill.

STREATER, ILL.—The Streater Gas and Light Company has been incorporated at this place, with a capital stock of $100,000. Address W. R. Gillett for particulars.

HAMILTON, ONT.—The plant of the Hamilton Electric Light Company is to be increased.

LOGAN, UTAH.—An electric light plant to have a capacity of 1,000 lights is to be established at this place.

PEORIA, ILL.—An electric light and gas plant is to be established at this place by the Peoria Gas and Electric Light Company. Estimated cost, $750,000. Address F. C. Crowley for details.

CAIRO, ILL.—The Citizens' Electric Light and Power Company will establish a plant at this place, at an estimated cost of $20,000. Henry Wells can furnish particulars.

HOT SPRINGS, ARK.—Reports say that the Hot Springs Electric Light Company will put in a plant with a capacity for about 1,500 incandescent lights.

GARDEN CITY, ILL.—The Garden City Electric Light and Power Company will establish a plant at this place. Estimated cost, $25,000. Address C. A. Buell, for particulars.

COMO, N. J.—An electric light plant will be established here by Henry H. Yard. Como, Belmar, Spring Lake and Sea Girt are to be lighted.

HAYWARDS, CAL.—An electric light plant is to be established at this place by S. D. Ingram and others.

QUINCY, ILL.—The Quincy Gas and Electric Light Company has been incorporated at this place to establish a plant. Estimated outlay, $400,000. Address, for details, Marion Pickett, as above.

BLAINE, WASH.—An electric light plant is to be established at this place by the Blaine Electric Light and Power Company. Cash capital, $50,000.

ST. PAUL, MINN.—Incorporated is the Grand Forks, Minn., Water, Light and Power Company, to construct electric light and power plants at that place. The capital stock is $100,000 and the incorporators are L P Ordway, Charles S. Rogers and others.

TECUMSEH, MICH.—An electric light plant will be established here by a local company, with a cash capital of $30,000.

DETROIT, MICH—The United Electric Company has been incorporated at this place with a capital stock of $50,000.

FAIRBURY, NEB.—The people of this place are discussing the electric light question.

KALAMAZOO, MICH.—Improvements and extensions are to be made to the local electric light plant.

TARPON SPRINGS, FLA.—An electric lighting plant is to be established at this place by the Occidental and Improvement Company.

WOODVILLE, PA.—The people of this place have voted for electric lights.

MACON, MO.—This place is to establish an electric lighting plant.

STUART, IOWA.—The Hawkeye Electric Manufacturing Company, of Davenport, Iowa, proposes to establish an electric light plant here. Neal Wilkin, of the above concern, can furnish particulars.

BINGHAMTON, N. Y.—This place is to have electric lights. Address, for details, Geo. W. Dunn, as above.

ELECTRIC RAILWAYS.—New electric railways will be established, and improvements will be made to those already built, at the following places: College Point, N. Y.; Brooklyn, N. Y.; Salem, Mass.; Newton, Mass.; Prescott, Arizona; Cairo, Ill.; Milwaukee, Wis.; Newark, N. J.; Orange, N. J.

GOVERNMENT WORK.

WASHINGTON, D. C.—The following proposals for the work specified at the places named were opened on the given dates by the Supervising Architect of the Treasury Department:

Plattsburg, N. Y.—Steam heating apparatus, low pressure, for the United States Court House and Post Office at this place. Opened June 18. Bidders: John Lyon, Washington, D. C., $2,548.88; Thos. Costello, Plattsburg, N. Y., $3,769; Kelly, Jones & Co., Elmira, N. Y., $3,093; Jas. & R. H. Walker, Baltimore, Md., $3,416 87; Q. M. Evans Construction Co., New York City, $4,227; Samuel I. Pope & Co., Chicago, $3,575; Chas. A. Crosley, New York City, $2,418.

Detroit, Mich.—Basement and area walls of the United States Custom House at this place. Opened June 18. Bidders: Jos. L. Gearing, Detroit, Mich., $167,365, pier granite, Bedford; $168,248, pier granite, Berea; $169,938, pier granite, Amherst blue stone; $171,414, pier granite, cream buff Amherst; $173,140, pier granite, blue Bedford; $175,928, pier granite, Prentice brown; $182,560, pier granite, Portage entry; $144,250, blue Bedford; $123,851, Berea and cream buff Amherst; $128,219, Berea and Prentice brown; $120,528, Berea; $124,183, blue Amherst; $130,667, buff Bedford; $141,461, blue Bedford; $180,565, Medina; $201,807, granite; $203,436, Minn. granite. E. F. Gobel, Chicago, $163,500, Ohio blue sandstone. Patrick Knapp, Detroit, $116,654, Bedford limestone. David Knapp, Detroit, $181,225, granite and limestone. A. Chapoton, Detroit, $178,495, Bedford lime; $213,495, granite throughout; $178,495, Berlin buff; $215,642, Louis Falls granite; $178,495; Amherst; $188,495, Portage red sandstone. McCarthy & Baldwin, Washington, D. C., $149,431, all granite; $132,609, granite and Indiana sandstone. John Moore, Syracuse, N. Y., $149,000, Bedford; $209,000, granite.

WASHINGTON, D. C.—The Secretary of the Navy, June 17, awarded to Samuel I. Moore & Co., of Elizabethport, N. J., at their bid of $250,000, the contract for the construction of a steel practice cruiser of 800 tons displacement, for which bids were opened on June 10. The contract for the armored cruiser has been awarded to William Cramp & Sons, of Philadelphia, Pa., at their bid of $2,985,000, on their own plans.

INDUSTRIAL.

ALBANY, N. Y.—The specifications for the lock lengthening, authorized by the last Legislature will, it is said, be ready in a few days, when proposals for doing the work will be wanted. Superintendent Hannan has also furnished plans, etc., for a new canal bridge at Rochester, and for dredging the Hudson River, between Troy and Coxsackie, and the work will soon be advertised.

UNION, N. J.—This place has voted the sum of $42,500 for public improvements.

POSITIONS VACANT.

TOO LATE FOR CLASSIFICATION.

THOROUGHLY QUALIFIED MECHANICAL Engineer desires position as Superintendent, or would act as agent for manufacturer. Undoubted references. Address "ENGINEER," care of THE ENGINEERING AND BUILDING RECORD, 1050 Drexel Building, Philadelphia. 4

PROPOSALS.

(Continued from page ii.)

PUMPING ENGINE, ETC., Mansfield, O.—Proposals are wanted until June 25, for furnishing a pumping engine and boilers. Address the Trustees of the Mansfield Water-Works, as above.

THE Editor of THE ENGINEERING AND BUILDING RECORD is always glad to receive items of news for the Contracting News Department. But such items are not considered news except when the prices and particulars of the award of a contract are given.

The announcement that ——— has sold ——— to ——— without giving the *prices* and particulars concerns only the buyer and seller. Such notices are always excluded, except in the case where a certain firm is stated to have taken a certain contract, the execution of which would require that they should buy certain materials. Such an item would be used if deemed of more than local interest, because it would suggest to some readers the possibility of their making a sale or securing a sub-contract.

Lindell av, br dwell; cost, $22,000; o, F W Humphrey.

Delmar av, br bldg; cost, $9,000; o, J N Booth.

ST. PAUL, MINN.—Nothing over $7,000 in value to report.

URBANA, O.—A City Hall will be erected here at a cost of $25,000. Address City Clerk, as above.

A $20,000 school house will be erected here. The Clerk of the Board of Education can give information.

UTICA, N. Y.—Architect W H Symonds has prepared plans for a $20,000 building here.

WALTHAM, MASS.—Nothing over $7,000 in value to report.

WATERLOO, IOWA.—Plans have been prepared for a $9,000 building at this place. Address I T Coolidge, as above.

WILKES BARRE, PA.—Public square, br store and dwell; cost, $11,000; a, M Burgunder; b, M B Houpt.

WINCHESTER, KY.—A factory building will be erected here at an estimated cost of $23,000. Address architects E F and W S Brickell, Olean, N. Y.

WINDSOR, ONT.—A $20,000 school building will be erected here. Address architect J G McLean, 9 Medbury Building, as above.

WORCESTER, MASS.—Salisbury st, br bldg; cost, $15,000; o, Society of Antiquity; a, Barker & Nourse; b, not let.

South Worcester, fr dwell; cost, $7,000; o, St Matthew's Episcopal Church; a and b, J B Woodworth.

Front st, alteration of business block; cost, $8,000; o, R C Taylor; a and b, J W Patstone.

ZANESVILLE, O.—Nothing over $7,000 in value to report.

THE ENGINEERING & BUILDING RECORD
AND
THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D.C.

VOLUME 22. NUMBER 4. | PUBLISHED EVERY SATURDAY. 277 PEARL ST., NEW YORK.

NEW YORK, JUNE 28, 1890.
LONDON, JULY 12, 1890.

SINGLE COPIES, TEN CENTS. Subscription, $4.00 per year in advance, post paid. } IN AMERICA.
SINGLE COPIES SIXPENCE. Subscription, 20s. per annum in advance, post paid. } IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.
20s. in GREAT BRITAIN. Other Foreign Countries $5.
Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & CO., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $5; China, Japan, Sandwich Islands, Mexico and Cuba, $5; South America, $5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

TABLE OF CONTENTS.

EDITORIALS:

Street Intersections on Steep Grades 49

Contracting Intelligence 62-63

STREET INTERSECTIONS ON STEEP GRADES.

OF all the problems that confront the city engineer in planning a system of street grades perhaps the most difficult is to determine the proper arrangement of a street intersection where one or both streets have much inclination, since to avoid excessive side slopes on one street it is necessary to increase the grade of the other and *vice versa*, and the proper balance between the two is not easy to settle, especially as the whole question is further complicated by the requirements of the intersecting sidewalks.

The simplest and, as far as side slopes are concerned, the best solution would be to keep the intersection level, with all corners at the same elevation, but this is not necessary on light grades and much increases the steepness of heavy ones, besides introducing an unsightly break in the vertical alignment, so that it can only be viewed as a condition which, however desirable for some reasons, can only be approximated and never realized, except when both streets rise or fall both ways from the intersection. On the other hand, to continue steep grades across intersections has the effect of introducing dangerous side slopes in the streets that are thus crossed, and the result is that the grades at intersections are practically a sort of compromise between what we would and what we must.

Unfortunately this compromise is seldom determined by any fixed rule, the grades being usually "fudged" according to the judgment or convenience of the engineer, resulting in great irregularity in practice and much uncertainty in securing the most satisfactory results. It is for this reason that we desire to call special attention to the careful treatment which this subject has received in the recent report of Rudolph Hering and Andrew Rosewater on the Sewerage and Paving of Duluth, of which an extended abstract is given elsewhere in this issue. The arrangement of grades at intersections therein recommended, although designed on general principles, agrees closely with what has been found to be good practice in Duluth and will therefore answer for any other locality, for no steeper grades are practicable there or elsewhere than those for which this arrangement was intended.

Our object in calling attention to this report, however, is not so much to point out its merits, which will be sufficiently obvious to those who have studied the matter, as to invite criticism and discussion and especially some relation of experience in regard to a subject of very general interest to city engineers, but about which, as far as we can learn, little or no general discussion has ever been had.

In such a discussion the following questions might be of special interest, namely: Whether at intersections it is better to adopt certain maximum slopes or to make the slopes bear a certain proportion to those of the intersecting streets, and what those maxima or proportions should be? What is a safe slope on the diagonal from corner to corner at intersections, considering the effect of centrifugal force on vehicles turning the corners and how it would be effected by crowning the streets? How to avoid having the sidewalk higher at the curb than at the house line on steep intersections without causing an excessive side slope in the intersecting sidewalk, and under what circumstances it is advisable to introduce steps in the sidewalks to avoid abrupt steeping of the grade. On these and similar points we have no doubt that some of our readers can contribute valuable information.

RECORDS OF UNDERGROUND STREET WORK IN NEW YORK.

IT is peculiar, to put it mildly, that while the space underneath the streets of New York is given up to a network of pipes of various kinds to supply public needs, all nominally under the supervision of the Department of Public Works, the latter is to-day almost completely ignorant of the character and general arrangement of the underground work, or, at best, knows little more about it than the average citizen. Water pipes and sewers have perhaps been kept track of more or less carefully, but the disposition of steam and gas pipes, electric conduits, pneumatic tubes, etc., is something upon which the Department is hopelessly in the dark. And yet it is but reasonable to think that this matter is strictly within its province, and that full information should be in its possession of the exact location, character, and purpose of every pipe buried in the streets. Just why the Department knows next to nothing of all this is one of the many interesting questions pertaining to the local government which the citizens are left to answer for themselves.

The gas companies, the electric companies, and the steam company, and the several other establishments having underground systems, each know where to find their conduits when, for some reason, they are to be unearthed, but there is not in existence a single map showing the positions which these subterranean pipes occupy relatively to one another at the present time. When the New York Steam Company began operations about nine or ten years ago, the work of preparing a map of this kind was taken in hand and, for a time, was conscientiously carried out. This map was, and is to-day, the only one of its kind and is an example of what, on a comprehensive scale, would be available in the Department of Public Works if the management there had been carried out judiciously and on a common sense basis. The lack of such information as a map of this kind would give was very strikingly brought to light on the occasion of the recent explosion at the corner of Broadway and Fulton Street. That there were there steam pipes, gas pipes, water pipes, sewers and various electric conduits was, of course, taken for granted, but, in truth, nobody knew, or knows now, anything definite about it. The utter ignorance, in fact, of the underground character of the streets at what ought to be the proper source of authoritative information on the subject would be laughable were it not so serious a matter. The street work records—called so by courtesy—of the Department of Public Works of New York are indeed aptly comparable to those which many small country towns are supposed to have of their street systems of water supply and other underground pipes, the details of which, after they are once covered up, are, and remain, unknown except when brought to light by experimental excavation.

It is not too late, however, even now to remedy all this. For a practically small sum of money a serviceable chart of what is beneath the streets could readily be made. Its need has been demonstrated over and over again. Let the preparation of such records be insisted upon and there will then be available, moreover, a rational and sound basis upon which to discuss the imperative questions of street and subway engineering.

BRIDGEPORT MACADAM ROADS.

THE Bridgeport, Conn., *Standard*, in a notice of the book "Pavements and Roads," recently issued from this office, quotes fully from the discussion on thin roads at Bridgeport between E. P. North, who described them in these columns, and James Owen, of Newark, N. J., saying in conclusion:

> Since these articles were written considerable has been added to the mileage of Bridgeport's good roads, and hundreds of visitors from all over the country have inspected them and the methods used in their construction, and have given testimony of their worth. It is no longer an open question whether they are practicable or not, for Bridgeport has settled that in the affirmative, and her example is being followed in many places where the best roads possible for a small outlay are desired. We do not know whether Mr. Owen, of New Jersey, has ever been here to see our roads or not, but we trust that if he has not he will soon come, and that Mr. Pierce and the gentlemen of the Board of Public Works will do the honors.

TROY POLYTECHNIC ALUMNI MEETING.

THE annual dinner of the Alumni Association of the Rensselaer Polytechnic Institute was held at Troy, N. Y., Tuesday evening, June 17, with about 60 members and guests present, and the annual meeting was held the next day. There was considerable discussion of Institute affairs, including the advisability of eliminating French, German and botany from the course, but no definite action was taken. In connection with the annual register a resolution was adopted requesting any person who knew the address of a former member of the Institute who was not a graduate to forward it to the director.

A resolution was also adopted making the Institute diploma sufficient for membership in the Alumni Association, abolishing initiation fees and including the graduating class among those to whom the Treasurer's circular shall be sent. William H. Doughty, Joseph C. Platt, Jr., and C. C. Waite, were appointed a committee to arrange for getting the subscriptions of classes to the building fund as speedily as possible.

Officers were elected as follows: President, J. J. Albright, '68; First Vice-President, Clark Fisher, '58; Second Vice-President, W. H. Doughty, '58; Third Vice-President, W. B. Cogswell, '52; Recording Secretary, W. P. Mason, '74; Corresponding Secretary, C. W. Crockett, '84; Treasurer, J. H. Caldwell, '86; Directors, Elias P. Mann, '72; E. Ray Thompson, '76; Joseph A. Powers, '80; Montgomery Waddell, '84; E. S. Kibbe, '86; Necrological Secretary, H. B. Nason. Townsend V. Church, Treasurer, submitted his report, which was adopted. The report showed that there was $60 cash on hand. There are no outstanding debts.

NOTES.

THE Columbus Branch of the Ohio Society of Civil Engineers has dissolved because of want of interest in the organization among members.

A PROJECT for building a second large hotel in New York City by the Astors is announced. It is to front 100 feet on Fifth Avenue and 125 feet on Fifty-ninth Street 14 stories high, and cost $1,100,000. Work will begin next fall, and the building is to be finished in 1892. It is also annnounced that P. H. Drugo and Frederick Wagner will build an 11-story hotel on another corner at the intersection of the same streets, at a cost of $650,000, excluding the land.

THE University of Vermont conferred the degree of Civil Engineer this week upon graduates as follows: Asaph T. Brookins, Shoreham, Vt.; George H. Claflin, Westfield, N. Y.; Eddy S. Jackson, South Walden, Vt.; Herbert M. McIntosh, Bethel, Vt., and John M. Perham, Brookfield, Vt.

THE Building Committee of the London County Council has reported against permitting a manufacturing concern to erect a wrought-iron chimney stack because "in view of the public safety the Committee had no option but to refuse permission for the erection of iron factory chimneys, which were likely to become dangerous after twenty years or less." The Committee's recommendation was agreed to by a large majority.

NOTICE is given in the London *Engineer* that the owners of that publication have organized a joint stock company for conducting the business. The new arrangement is accompanied by no change in management, and is made as a matter of business convenience.

THERE was still another subway explosion in New York City Monday, this time in an electric subway manhole at the corner of Sixth Avenue and Twelfth Street. The manhole cover was thrown up and the brickwork, etc., somewhat disturbed, but there was no person injured.

A FIRE at the old pumping-works station of the waterworks at Nashville, Tenn., the other day, disabled the engines. One of the engines in the new station is being repaired, and there are some fears of a troublesome scarcity of water.

OBITUARY.

H. L. HIGDON, engineer on the Wichita Valley Railroad, died at Lampasas, Tex., June 11.

FRANK MONTGOMERY, C. E., of Hancock, N. Y., died at Boca Negra, Mexico, June 1, from injuries received in a railroad accident.

FRANK H. ANDREWS, of New York City, President of the Globe Iron and Spring Works and Secretary and Treasurer of the Baker Heating Company, died June 21, aged 38 years.

WILLIAM SEARS, of Newton, Mass., died Wednesday at the age of 86. Mr. Sears was a contractor and builder. He built 30 churches in Boston, and most of the depots, stations and freight houses on the Worcester, Old Colony, Fitchburg, and Eastern Railroads. Mr. Sears obtained the charter and called the first meeting to organize the Northern Pacific Railroad Company, and was in the Board of Directors five years.

CHARLES ACKENHEIL, M. Am. Soc. C. E., Chief Engineer of the New York extension of the Baltimore and Ohio Railroad, of the Staten Island Rapid Transit Company and of the Baltimore and New York Railroad, was killed in an accident to a train on the Baltimore and Ohio Railroad June 20. Mr. Ackenheil was born in Baden-Baden and educated at Heidelburg, came to this country from Germany 20 years ago, and had been continuously with the Baltimore and Ohio Railroad except for a short time of service on the Rochester and Pittsburg Railroad. He designed the Arthur Kill bridge and was in charge of the projected improvements of the Baltimore and Ohio Road on Staten Island. He was 48 years old.

PERSONAL.

CHARLES W. BORLAND, County Surveyor of Lancaster, O., has been elected City Engineer of his city.

JOHN Y. CUYLER has been appointed Consulting Engineer by the Brooklyn, N. Y., Park Commission.

ROBERT M SAUP has been re-elected Superintendent of the Zanesville, O., Water-Works.

H. C. BABBITT, civil and sanitary engineer, of Columbus, O., has been elected City Engineer of Sidney, O.

L. S. WAKEFIELD, of Sioux City, Iowa, has been appointed Chief Engineer of the Pacific Short Line Railroad.

CHARLES F. MCKIM, architect, of New York City, was given the honorary degree of Master of Arts by Harvard College this week.

PHILIP GOLAY has been appointed Engineer in Charge of Government Locks and Dams on the Monongahela River, with headquarters at Morgantown, W. Va.

PROFESSOR R. C. CARPENTER, of the Michigan Agricultural College, has been appointed to a professorship in Cornell University, and will move to Ithaca, N. Y., in August.

WILLIAM T. GOULD has resigned his position on the Mobile and Ohio Railroad to accept a position as Resident Engineer of Construction on the Northern Pacific Railroad.

THOMAS J. JOHNSON, Consulting Engineer of Savannah, Ga., has been appointed Assistant Engineer of the Chicago Drainage Commission, with charge of technical investigations.

WILLIAM T. BLUNT, of Cleveland, O., Engineer on Harbor Improvements on Lake Erie, has been appointed Assistant Engineer of the Chicago Drainage Commission, with charge of surveys.

F. MEREDITH JONES, recently connected with the Southern Mexican Railway, has been appointed Chief Engineer of the Vera Cruz Land and Construction Company, with headquarters at Mizantha.

W. A. VAUGHAN, Superintendent of the Saginaw and Mackinaw Division of the Michigan Central Railroad, will, on July 1, become the General Superintendent of the East Tennessee, Virginia and Georgia Road.

WILLIAM M. REESE, of Memphis, Tenn., Engineer on the Mississippi River Improvements, has been elected Assistant Engineer of the Chicago Drainage Commission, in charge of investigations pertaining to construction.

LIEUTENANT COLONEL RICHARD N. BATCHELDER has been appointed Quartermaster-General by President Harrison, with the rank of brigadier-general. He was chief quartermaster of the army of the Potomac during the war, and it is announced that he is appointed on his record.

PROF. GEORGE W. PLYMPTON has been appointed by Mayor Chapin of Brooklyn member of the Board of Experts on the terminals of the Brooklyn Bridge. This appointment, with those of Mr. Bucholz and Mr. Spencer made, respectively, by President Howell of the Bridge Company and Mayor Grant of New York, fills the Board. Mr. Plympton is Professor of Physical Science and Engineering in the Polytechnic Institute of Brooklyn.

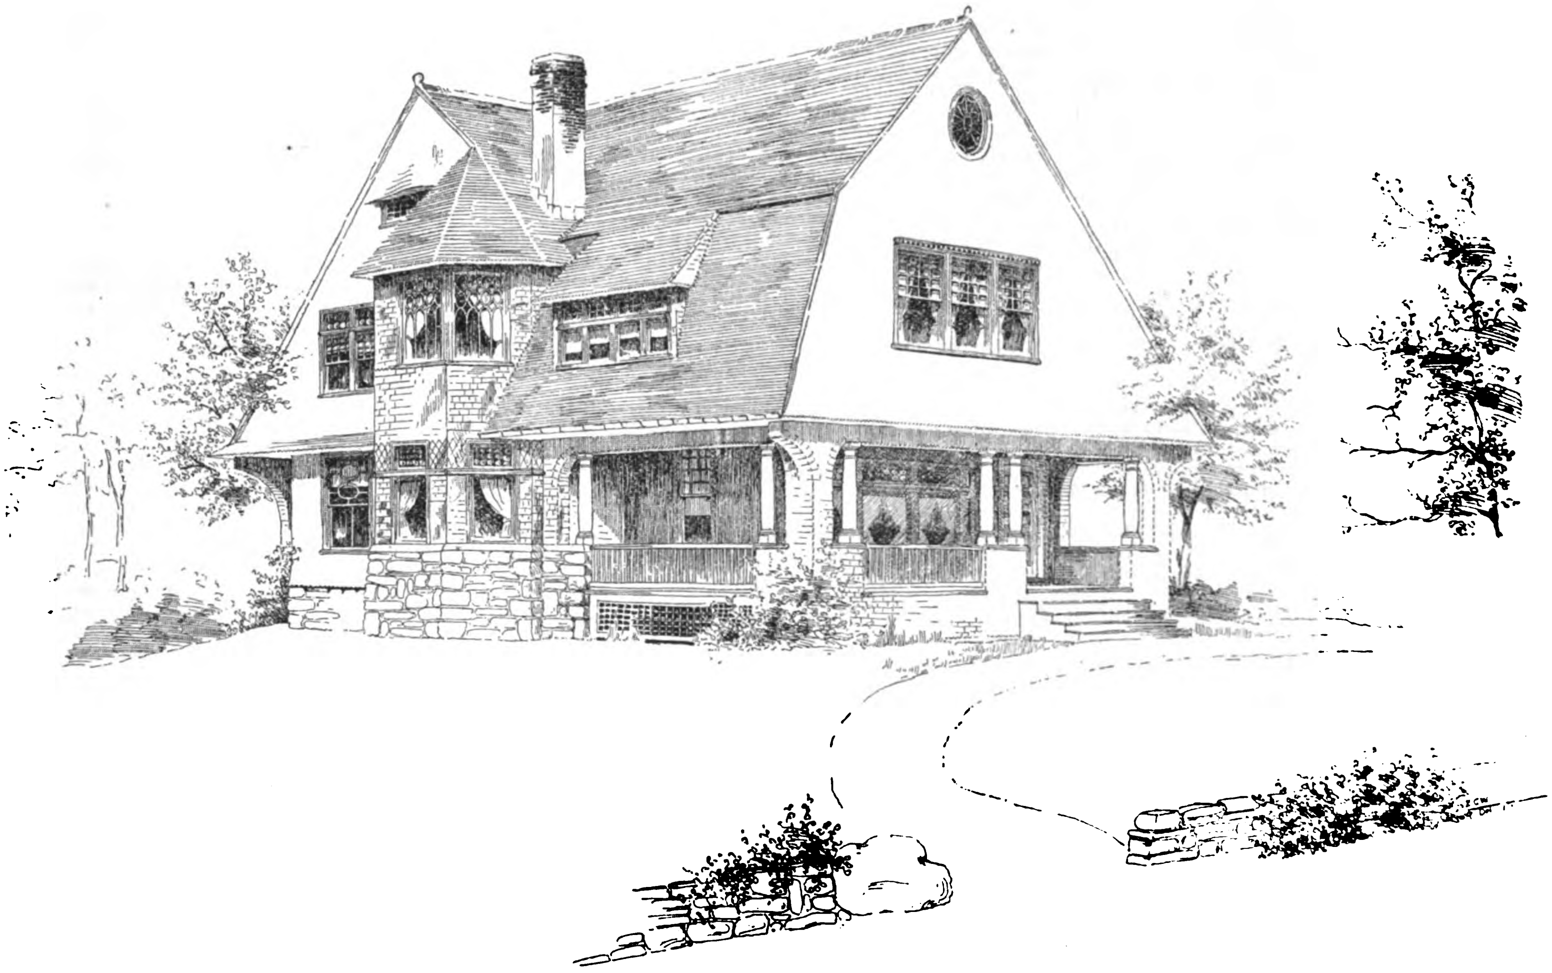
ENGINEERING SOCIETIES.

THE ENGINEERS' CLUB OF ST. LOUIS held a meeting June 18, with Vice-President Burnet in the chair, W. H. Bryan, Secretary, and 17 members and 3 visitors present.

The Secretary read Professor Charles C. Brown's paper on "River Pollution in the United States." The author treated streams used for water-supply only, streams used for drainage purposes only, and streams used for both water-supply and drainage. The paper was confined principally to the consideration of the latter class. The author gave some account of the work done in different States investigating the pollution of streams, accompanying his remarks by tables showing the results of chemical analysis of a large number of samples of water. There was brief discussion by Messrs. Beahan, Seddon and Holman.

THE MINNEAPOLIS ENGINEERS' CLUB at the June meeting listened to a paper by Walter S. Pardee, architect of the Minneapolis Board of Education, on "The Ventilation of Public School Buildings." The paper was illustrated by diagrams. President William A. Pike was chosen to represent the club at the Cresson convention of the American Society of Civil Engineers.



HOUSE OF WILLIAM H. STEELE, RUTLAND, VT.—E. G. W. DIETRICH, ARCHITECT, NEW YORK CITY.

(For plans see opposite page.)

ARCHITECTURE AND DEMOCRACY.

Harpers' Magazine for July contains a suggestive and hopeful article by Robert S. Peabody, architect, of Boston, in which the author endeavors to show "that architecture has flourished, and that most vigorously when the common people were the only masters of the State; that the rise and wane of its glorious periods have occurred impartially under monarchies, empires, republics and democracies, and that popular power has not heretofore stood in the way of progress in the art of building." Conspicuous examples of Italian work in the 13th century are cited to support this claim, and notwithstanding the fact that a distinguished professor is quoted as saying that "there is no hope for real literature or art, so hopelessly vulgar and sordid is American life," Mr. Peabody records numerous examples to justify his faith that the "hope of the future in art, as in many other fields of human endeavor, lies, as the years go on, with our ambitious, prosperous and appreciative democracy."

LETTER FROM ENGLAND.

LONDON, June 12, 1890.

THE Sanitary Institute announces that a deputation of their members has visited Brighton with a view to the arrangement of the congress and exhibition to be held there at the end of August. The pavilion buildings will be utilized, the large dome, the corn exchange and the picture gallery being all devoted to the purpose. The secretary states that applications for space are considerably in excess of those for previous exhibitions, and that there will be some difficulty in meeting the wishes of intending exhibitors.

The Council on Education has inaugurated the system of state grants in support of technical education by voting the sum of £5,000 for grants-in-aid during the financial year of 1891–92. The minute accompanying the vote states that teaching must be in the use of the ordinary tools used in handicrafts in wood or iron, given out of school hours in a properly fitted workshop, and connected with the instruction of drawing. That is to say, the works must be in drawings to scale previously made by the students. This is undoubtedly a step in the right direction, inasmuch as the inability to make and work from drawings is one of the most pronounced features of the present day amongst the general body of handicraftsmen.

The question of nuisance arising from destructors for ordinary refuse is of course one vitally affecting the adoption of this article. There has been for some time past considerable complaint in connection with a destructor belonging to the Commissioners of Sewers of the city of London, situated in Lambeth, and the Local Government Board has been appealed to in the matter. Mr. Ritchie, the president of the Local Government Board, in reply to a question in the House of Commons, stated that the inspector of the Board had examined the structure and its working. Mr. Fletcher had reported that if the refuse were wholly burnt no smell would arise, but owing to the absence of a combustion chamber it could not be kept throughout at a strong red heat so that the gases from the furnace could be completely burnt. He was of opinion that there was reason to believe that some of the sickly smelling steam and smoke which was given off from the refuse while in the early process of combustion constituted the nuisance. The Commissioners of Sewers have been required to remedy the evil, which is, of course, self evident. The matter is simply quoted as affording a warning to local authorities desirous of adopting destructors, who may have lost sight of the advisability of having either a reverberatory arch or such combustion chamber for the gases as is suggested.

Crewkern, in Somerset, is not to be congratulated for the wisdom of its sanitary authority. Charles Hawkesley, C. E., having been called in to advise as to the cost of precipitating works for the sewage of the town, has estimated it at £4,200 for the northern outfall and £6,200 for the eastern. Further, that if the sewage is carried to one common point cost would be £13,500. Certain local experts and wiseacres have written the Local Board, in one case offering to cleanse the sewage at the rate of 2*s*. 3*d*. per head, the number of inhabitants being put at 6,000, while another offers to treat the sewage of the northern outfall for five years at £300 per annum. The intelligent gentry in whose hands is placed the sanitary authority of the district have invited the gentleman who offers to undertake the northern outfall at £300 per annum to meet them and go into the matter. Developments will be interesting.

AN ARCHITECTS AND ENGINEERS CONVENTION IN HAMBURG.

AMERICAN engineers in Europe this summer may be interested to know that the ninth meeting of the Union of German Architects and Engineers' Associations is to be held at Hamburg from the 24th to the 30th of August. Hamburg is a beautiful city and interesting to the engineer. Among the addresses to be delivered on the occasion may be mentioned "The Modern Tasks in the Construction of Streets in Great Towns with Regard to the Laying of Pipes, Etc.," by Dr. Hobrecht, Municipal Building Councilor, Berlin; "Recent Fast Steamers in the Mercantile Marine and Navy, and Their Motive Power," by Mr. Busley, Imperial Naval Engineer, Kiel; "The North Baltic Canal," by Privy Councilor Baensch; "Recent Wide-Span River Bridges," by Mr. Mehrtens, Railway Construction and Traffic Inspector, Bromberg. A number of inspections and excursions are to be undertaken, among which may be mentioned a walk through the new free haven district, a trip on a steamer to inspect the new docks, Elbe Bridge, etc., a trip to the outer Alster and the Alsterlust, a trip to the new transatlantic steamer "Columbia," of the Hamburg-American line, to the North Sea and Cuxhaven, a trip by railway to Kiel to inspect the dockyard and war ships, an inspection of the town of Lubeck and of the North-Baltic Canal.

THE CAUSE OF THE ACCIDENT TO THE "CITY OF PARIS."

THE Board of Trade Court of Inquiry, at London, which has been investigating the causes of the recent accident to the Inman Line steamer "City of Paris," made its report June 21. The Court attributes the casualty to the wearing of the propeller bearing.

In the judgment of the Court full provision was made to insure the vessel's safety as an ocean-going steamer, and safety was not sacrificed to speed. The propeller shafts, both inboard and outboard, appeared to have been sufficiently supported, and those of the port engines showed little or no signs of wearing.

The Court finds that the ship was properly constructed in all respects. The primary cause of the accident was the extraordinary wearing down of the ring in the bracket supporting the extreme end of the propeller shaft, whereby the end dropped from its proper position about seven inches, thus producing a bending effect on the shaft at its forward support coexistent with each revolution of the engine. This probably produced a rupture of the external surfaces, gradually extending inward, and finally a total fracture.

The cause of the water finding its way into the engine room and other compartments was that a large portion of the low-pressure cylinder fell, or was driven against the condenser, tearing away and thereby opening a large communication with the sea, through which the water rushed in such volume that before any of the inlets could be closed they became covered with water and out of reach. The water passed into the dynamo room and port engine room through the bulkheads, broken by the ruptured machinery, and into two compartments by injury to the valve box in the engine room. In conclusion the Court says:

> After the practically unanimous testimony of eminent authorities in the Board of Trade and the Lloyds and other experts upon the strength, completeness and efficiency in all respects of the ship for the service for which she was especially designed and built, the Court does not consider itself in a position to offer suggestion thereon. During the course of the inquiry we have had evidence that even if some of the forward compartments of the ship had been filled with water, in addition to those filled, she would still have had a fair amount of freeboard and been able to float.
>
> We are of the opinion that, having a fair regard for the trying ordeal through which she passed, the vessel proved to be one of the finest and safest vessels in the mercantile marine.

TEST OF BOILERS AT THE PAWTUCKET PUMPING STATION.

IN determining the influence of the steam jacket on the Pawtucket pumping engine, as described on page 74, Professor Denton found it necessary to determine separately the efficiency of the boilers and incidentally the economic value of different kinds of coal. Some of his conclusions on these points as given in a letter to Edwin Darling, Superintendent of the Pawtucket Water-Works, are contained in the following extracts:

I was enabled to make the experiments on the No. 1 Pawtucket Pumping Engine, under the following conditions. The engine having been overhauled as usual in March to prepare for the summer run, it should be taken in the condition it might be found, without any extra preparation except the insertion of wells in steam and water pipes for thermometers and valves for meter appliances; also that the usual coal which had been purchased for the season should be used in making the test, the idea being to have the engine tested under the conditions common to its regular daily work.

The experiments had for their special object the measurement of the steam consumed by the engine per horsepower under various conditions calculated to afford scientific data regarding the application of thermo-dynamic principles in engines of this type. This required the separation of the performance of the boiler from that of the engine. The engine had been several times previously tested without making this separation, the performance being stated in foot pounds of "duty," which expresses the combined economy of the engine and boiler. I had formed the opinion, during several years of acquaintance with the engine, that the high "duty" performed was gotten with a rather inferior efficiency on the part of the boilers, thereby making the probable efficiency of the engine abnormally high even for its type and conditions of special excellence. Having communicated this idea to friends interested in the applications of steam engines through their manufacture and otherwise, I succeeded in securing the subscription of sufficient funds to defray the expenses of the test, outside of the pipe-fitting and like labor, which you kindly volunteered to take upon yourself when assenting to my request to be allowed to make the experiments.

The results of the measurements do not confirm my idea regarding the unequal division of the economy between boiler and engine. The boiler is not of low efficiency, and the engine, while the most economical for its size, if not of any size, of which accounts have been published, does not reach the extraordinary figures I had been led to expect. The boiler evaporates 8.88 pounds of water from 104° Fahr. into steam of 127 pounds pressure with anthracite coal yielding 14 per cent. of ashes at 5 pounds rate of combustion, and 9.35 pounds of water from 104 degrees with Georges Creek bitumous coal yielding 10 per cent. of ashes at 5 pounds rate of combustion. The engine performs a horse-power of work in its steam cylinders with a consumption of 13.75[*] pounds of steam per hour. Taking into account the percentage of ashes, the performance of the boiler is practically the maximum economy to be expected or gotten from boilers, while the steam consumption of the engine is also unexcelled, as even the most improved marine engines of the triple expansion type using steam at 150 pounds pressure have yet to produce a record of steam consumption lower than 15 pounds of steam per hour per horse-power [†]

The combined efficiency of the boilers and engine gives a horse-power in the steam cylinders with 1.54 pounds of anthracite coal consumed per hour, and 1.48 pounds bituminous coal consumed per hour. Out of a horsepower produced in the steam cylinders 95 per cent. is available to force water, only about 5 per cent. being required to overcome the friction of the mechanism and operate the air pump, etc. In this respect also the engine is an extraordinary piece of apparatus.[‡] It results from all of the foregoing that the duty per 100 pounds of coal was for anthracite coal 124,750,000 foot pounds, and the duty per 100 pounds of coal was for bituminous coal 127,350,000 foot pounds. These figures are for the actual evaporation of the boilers as given above.

For the fictitious basis on the part of the builder of 10 pounds evaporation per pound of coal, the above figures for duty become 140 and 145 millions respectively. These figures for "duty" practically agree with those reported for the annual work of the engine in 1887 and 1888, when I understand the engine to have run without banking of fires for long periods of time, so that the effect of banking and starting fires in increasing the coal consumption was eliminated, as was the case in my experiments. Should the engine be worked days only, so that banking and starting of fires is required every 10 or 12 hours, then the reduction of duty should by my observation of the working of your station be about as follows:

To obtain a duty of 124 millions it is necessary that the coal consumption should average 200 pounds per hour, with 100 pounds every six hours for cleaning fires. Suppose the engine is run 12 hours daily, then at about half after the eleventh hour 200 pounds of coal is fired, and at the twelfth hour the 100 pounds of coal which would be used for cleaning, if the engine was not stopped, is used for banking. During the 11 hours that the fires are banked steam falls to about 80 pounds. To raise steam to running pressure requires 300 pounds of coal, and about 25 minutes after the engine is started 200 pounds more coal are used. At the end of the first hour and 25 minutes of running 200 pounds are again fired and there after the same amount is fired per hour.

To run the engine 12 hours, therefore, the consumption is as follows:

11 hours of steady firing, 2,200+200 for cleaning,	2,400 pounds.
Raising steam and first 25 minutes	500 "
Total	2,900 "

If the engine was running continuously there would have been required for the same 12 hours of work by the engine 12 times 200 plus 200 for cleaning, 2,600 pounds.

The banking therefore requires $\frac{29}{26} = 1.11$ times as much coal as continuous running.

Hence 124 millions duty for continuous running is consistent with $\frac{124}{1.11} = 110,000,000$ foot pounds "duty" for day service requiring banking.

The reverse of this is therefore also true, namely, that if, as appears from the reports of the engine, about 110 millions duty was performed during daily running and using banked fires, it is reasonable that about 124 millions should be performed during the continuous running in 1887–88.

* * * * * * *

Three boilers were used. The grate surface in each boiler was a circle 4⅓ feet in diameter and 15 square feet in area. Each boiler was a cylinder 14 feet long and 4 feet in diameter, suspended vertically in brickwork and having 48 3-inch tubes running from end to end. The total heating surface in the three boilers was 1,231 square feet in contact with water and 508 square feet of superheating surface.

The boiler flues had been swept clean about five days previous to the test. As soon as the fires were evenly ignited the fireman was limited to 200 lbs. of coal per hour, with an extra allowance of 100 lbs. for cleaning every six hours.

So nicely was the firing under control that the furnace doors were scarcely ever opened to look at the fires between the hours. As the hour approached, the allotted 200 lbs. were loaded upon a barrow and brought close to the furnace of one boiler. The damper of this boiler was then closed, the fire door opened and one-third of the barrow-load quickly but accurately distributed evenly over the grate, and the same operation was repeated with the other two boilers. Each fire door was open less than one minute.

When the fire was cleaned the engineer assisted the fireman, one using the slice-bar and the other withdrawing the clinkers. The cleaning, including the addition of one-third of the allotted 100 lbs. of extra coal, was accomplished in about three minutes for each fire. On several occasions the whole of the 100 lbs. of cleaning coal was not required.

The above refers to the 72-hours' test, during which the fuel was mainly stove anthracite. It is the practice of the station to screen this coal on a 1-inch square mesh, thereby freeing it of all small pieces of the size equivalent to nut coal. The small size, or that which falls through the screen, is used for banking the fires, while the larger or stove size is used for the bulk of the work. The small screenings were used for starting the fires.

The refuse of the anthracite coal collected in the ash pits was 752 lbs. This was screened through a ⅜-inch mesh and 110 lbs. of unburnt coal obtained. This coal was put on the fires during the last or 72d hour of the test, after the firing with fresh coal had ceased. The clinkers removed during the cleaning of fires amounted to 653 lbs. The contents of the grates at the end of the test amounted to 944 lbs.

The anthracite coal was therefore as follows:

Total coal fired	15,710 lbs	
Wood, taken as equivalent to 40 per cent. of coal	105	
Total fuel used		15,815 lbs.
Consumption per hour	219.5	
Incombustible from ash pits	641	
Incombustible clinkers	653	
Left in furnaces	944	
Total		2,238
Total combustible		13,577

Total refuse equals 14.3 per cent. of fuel.

The bituminous coal made no clinkers, and the fires were not cleaned during the entire 24 hours of its use. No separation of the ashes was made, the total refuse from ash pits and grates combined being 510 lbs.

The total consumption was:

Coal	5,200 lbs.
Wood	80 "
Total in the 24 hours	5,280

Consumption per hour, 218.6.

Ashes equal 9.6 per cent. of fuel.

I regard the above details of firing, etc., as worthy of note, from the fact that it is a matter of well founded opinion that a very sensible part of the performance of fuel depends upon the degree of skill displayed in the firing when the best results are obtained. Beyond doubt the extraordinary annual performance of the Pawtucket pumping engine is partly due to the high state of efficiency to which the routine firing and other details of management have been brought by Chief Engineer Walker's zeal and intelligence.

GOVERNMENT TESTS OF WOOD.

UNDER the above head the *Southern Lumberman* says: In compound columns care should be exercised in selecting the sticks which are to form the column. Of course it would be useless to place a poor with a strong stick, but it is best to place the good together and the inferior by themselves. To make the effects of knots in the resistance of short posts to compression more apparent, some columns, after having been tested and their resistance determined, were cut up and specimens of shorter length taken and tested; the difference in strength was very marked, as was to be expected. An oak column 168 inches long, which yielded at 4,953 pounds per square inch, showed in a specimen 52 inches long cut therefrom 8,450 pounds per square inch, and another 7,794 pounds per square inch, which then gave way at a knot. Another post 164 inches long failed at 3,432 pounds per square inch, but a piece 32 inches long was cut from it, which gave 6,230 pounds per square inch. A yellow pine post, 143 inches long, gave a resistance of 4,663 pounds per square inch, but a specimen 32 inches long was taken from it which had a resistance of 6,230 pounds per square inch. Pieces of smaller size could doubtless have been cut from each of these which would have shown still greater strength, as they might have been obtained more free from imperfections of all kinds. Knots of even small size, firm and sound, exercise an injurious effect upon timber. This was shown in a piece of spruce from which two samples were cut, one having a uniform, straight grain, the other two small knots; the strength of the former was 11 per cent. greater than the latter. When we come to determine the resistance of specimens having knots to forces of compression at right angles to fibers of the wood, we find the resistance much increased, and this increase should be taken into account when selections for this purpose are possible. The resistance of specimens of a given wood, as compared with others of its kind, is generally indicated by its specific gravity, but this does not always hold good. In yellow pines, some of those rich in turpentine have a high specific gravity, and yet are not the strongest. The rapidity of growth will sometimes give indications of the strength. A rapid growth in oak is apt to be accompanied by an increase of strength, while the reverse is often true in yellow pine.

---

[*] Duplicate tests gave 13.64 pounds and 13.83 pounds, respectively.

[‡] The principal features and dimensions of this engine are given on page 74. Its general arrangement is similar to that shown in the section of Pawtucket Pumping Station No. 3, on page 14, of Vol. XIX.

PROPOSED IMPROVEMENT OF SEWERAGE AND PAVING IN DULUTH.

THE Board of Public Works of Duluth, Minn., some months ago invited Rudolph Hering, of New York City, and Andrew Rosewater, of Omaha, Neb., to advise them in regard to the extension of their sewerage system, and also as to the pavements best adapted for the steep grades which are found in that place, and their report has just been published.

Duluth, with a population of over 20,000, is laid out for about six miles along the northwestern shore of Lake Superior, at its western extremity, but hardly averages a mile in width, and rises 500 feet or more in that distance, giving street grades in some cases as high as 32 per cent. These unusual conditions render both sewerage and paving problems of more than ordinary difficulty.

In 1883, when the population was about 5,000, and the expense of combined sewers could not be afforded, the sewerage of the city was commenced on the separate system in accordance with plans furnished by Mr. Hering. The aggregate length of sewers constructed to date is about 22 miles, over three-fourths of which are for foul water removal including roof water. The city has now so far developed that the underground removal of storm water has, according to the report, become necessary, or at least desirable in most cases, and the combined system is therefore recommended for certain parts of the city. In other places, however, it will be necessary to intercept the sewage at the water front and conduct it to a pumping station whence it can be forced out some distance into the lake while the storm water should be discharged as directly as possible, and here the separate system will be required. It may be a long while before it becomes necessary to pump the sewage, but the report states that even in the meantime the storm water should be excluded from the intercepters to prevent silting, except in the winter time, when, by a special device, the slight flow from the storm sewers may be thus discharged to prevent accumulation of ice on the flats at their outlets.

As the water supply of the city is taken from the lake the relative positions of the sewage outfall and the water intake become matters of much importance. In the large cities on the shores of the great lakes it has been found desirable to keep these points from six to ten miles apart, but a less distance is expected to suffice at Duluth, since its sewage seems to produce much less foulness in the lake than has been observed elsewhere. This is attributed to two causes, first the promptness with which, owing to the steep grades, the sewage is discharged, giving little opportunity for decomposition on its way, and reaching the lake comparatively fresh it is largely consumed as food by fishes, water fowl, etc., which are said to frequent the outfall, and, second, the coldness of the water even in summer, which retards decomposition even after the sewage is discharged and thus prevents foulness. As the current along shore is usually southwesterly, a location is suggested for the water intake about five miles northeast of the proposed sewage outfall.

In proportioning the size of storm sewers to run full it is recommended that a flow of two cubic feet of rain water per second per acre be allowed for in areas of less than two blocks, diminishing to one and a half cubic feet for 100 acres, and further gradually diminishing in accordance with Burkli-Ziegler's or McMath's formulæ. The

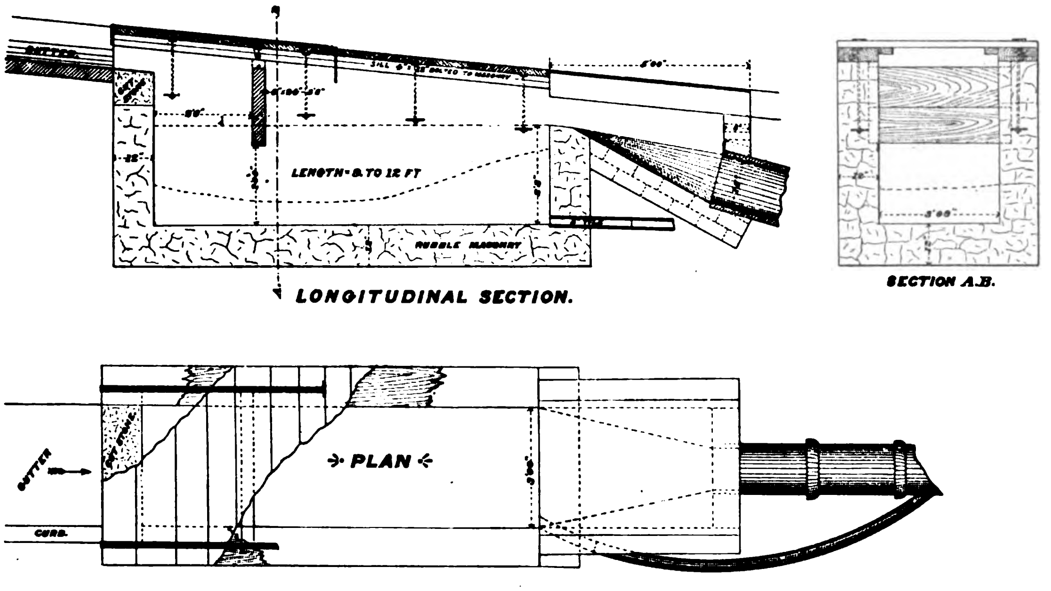
FIG. 1.

above is for the closely built up sections; for areas which will always remain residential three-fourths of the above are considered sufficient, with a still further reduction for park areas. As far as can be ascertained, the heaviest rainfalls in Duluth do not vary much from those in the northern portions of the Eastern and Middle States.

In view of the steep grades causing a more rapid flow it is assumed that one-half of the sewage will flow off in six hours instead of eight as is usually estimated. Roof water is to be admitted with the sewage to some extent even where the separate system is used, and provision is to be made for overflow into the storm sewers where necessary. Not only do the steep grades cause much sand and gravel to be washed into the sewers, but this, in connection with the high velocity of the flow, has already caused the sewers to show some signs of wear. To avoid this catch basins are recommended at street corners. They are to be of such capacity that the rate of flow through them will not exceed two feet per second and that the greatest amount of solid matter deposited by a single storm will not more than fill them. The accompanying illustration, Fig. 4, shows the construction proposed, in which a fender is placed to check the velocity of the inflow, sometimes over 20 feet per second, and a small drain leads from the bottom to keep the basin from standing full of water and to facilitate cleaning. At the upper end of graded avenues it may be found expedient to build specially large temporary catch basins of timber which, when the grading is extended, may be replaced by smaller ones of permanent construction.



LONGITUDINAL SECTION.

SECTION A.B.

→ PLAN ←

CATCH-BASIN

Fig. 4.

To keep out the larger refuse it is advised that the gutters of the graveled streets be covered by wooden gratings, as shown in Fig. 2 and in detail in Fig. 5, which are estimated to cost 15 to 25 cents per lineal foot. On steep streets not yet paved it is recommended that no crown be given, and by thus spreading the water from curb to curb its maximum depth and velocity, sometimes sufficient to carry stones eight inches in diameter, and consequent destructive effect will be much reduced.

No difficulty is apprehended from lack of ventilation; on the contrary, in winter, it becomes actually necessary to check the circulation of air as much as possible to prevent freezing in the sewers. Temporary wooden gates over the outfalls are recommended for this purpose.

In the construction of the sewers it is considered necessary, in order to ensure stability under such high velocities of flow, to have the sewers securely anchored into the body of the material in which they are laid by a substantial concrete bedding, with outward projections at suitable intervals. Inverts of granite slabs roughly hollowed or of granite blocks laid in cement are recommended for the storm sewers, to resist abrasion by the gravel, etc. Concrete sewers if of the best materials and well smoothed inside, and with anchor projections outside to prevent slipping, are considered suitable for either storm water or sewage. Existing sewers of Portland concrete have worn well, as have also those of clay pipe bedded in concrete. A storm sewer 40 to 48 inches in diameter built of brick with solid granite bottom on grades of 7½ to 12½ per cent. has given very good satisfaction.

In regard to street grades and the proper form for intersections, it is advised that no grades steeper than 16 per cent. be allowed, as they are practically useless for thoroughfares. If the difference of elevation between adjacent intersections would give a greater grade a retaining wall across the street is suggested, of sufficient height to reduce the grades on either side to reasonable limits. There would be stairs for pedestrians, but no thoroughfare for vehicles, which would have to reach the rear alleys from the nearest cross street. As a measure of economy the width of paving on such intercepted streets should be reduced from 42 to 30 feet with a corresponding increase in the width of the sidewalks.

In the business portions of the city it is recommended that wherever the grade exceeds 8 per cent. the curb should be broken at the street or property line, otherwise to be continuous and uniform between corners.

Figure 3 shows the arrangement of intersections on steep grades. From this it will be seen that at these intersections the grades are flattened to 3 per cent. for the width of the roadway of the intersecting streets, and that the grade of the curbs is flattened to 8 per cent. for the width of the intersecting sidewalks. Grades of less amount on roadway or sidewalk are continuous. The elevation of block corners is found by adding together the curb elevations at the points facing the block corner, and also the sum of the widths of the two sidewalks at the corner multiplied by 2½ per cent. and dividing the whole by 2. This gives an elevation equal to the average elevation of the curbs opposite the corner plus an average rise of 2½ per cent. across the width of the sidewalks.

On very steep grades it is recommended to reduce the alley width across sidewalks from 20 to 10 feet, and to flatten the sidewalk grade across that width to 10 per cent., so as to make it easier for vehicles to enter the alley, providing steps, if necessary, on either side to come again to the uniform grade of the street.

In considering the question of paving on steep grades much stress is laid on the importance of securing a good foundation for the wearing surface, preference being given to a concrete of broken stones and gravel in cement mortar, next, to a bed of compact layers of broken stone, then to gravel and last to sand, which is only suitable on the more level roads having a good natural bed. Where there is danger that moisture will penetrate the road-bed a line of blind drains is recommended laid below the curb and discharging into the corner inlets; while to keep the foundations from sliding on steep grades transverse bars or ribs of concrete, at suitable intervals, extending 6 to 12 inches into the soil are advised.

For ordinary grades the following pavements are recommended: For 10 per cent. or less, rectangular stone blocks with sand joints on concrete or broken stone foundation, costing $2 75 to $3.25 per square yard; for 6 per cent. or less, best paving brick laid on concrete, at $2.25 to $2.75 per square yard; ordinary round cedar blocks on concrete at $1.80 to $2 per square yard, or on broken stone and boards at $1.50 to $1.60; or rectangular pine blocks on concrete foundation at $2.25 to $2.40, and for less than 4 per cent. sheet asphaltum laid on concrete at $2.25 to $3 per square yard if maintained for five years, or $3 to $3.50 if maintained for ten years.

Macadam and Telford pavements are not recommended unless their upper layer is treated with coal tar, when it is believed that they may answer well for temporary pavements up to 16 per cent.

The pavements recommended for very steep grades are shown in Fig. 5. They are, first, for grades exceeding 10 per cent., rectangular stone blocks from 3½ to 4 inches in width and chamfered on the upper edges to give a foothold for the horses, estimated to cost on a broken stone foundation $2.75 to $3.25 per square yard, and on concrete $3 to $3.50, next, kidney or cobblestones of nearly equal size, not exceeding 3 inches in width, set in cement mortar on concrete foundation to cost $2 to $2.50 per square yard; and for grades exceeding 6 per cent. best paving brick of special form on concrete foundations at $2.50 to $3 or round cedar blocks 4 or 5 inches diameter chamfered to 3 inches at top, laid on concrete at $2 to $2.25 per square yard, or rectangular pine blocks either chamfered as shown in the drawing or plain 3 to 3½ inches wide, and set with 1 or 1¼-inch joints on concrete at a cost of $2.40 to $2.60 per square yard.

The pavements are recommended in the order named, and it is advised that the kidney, the brick and the cedar block pavements be tested by laying a block of each on some of the steeper avenues.

Statistics collected on the water-works at Greenville, Mich., by G. S. Williams, show that it actually cost less to buy and put in a 6-inch pipe to reach one block with a hydrant at the end of it, than it would to buy 2½ inch hose to reach the same block with a nozzle at the end of it.

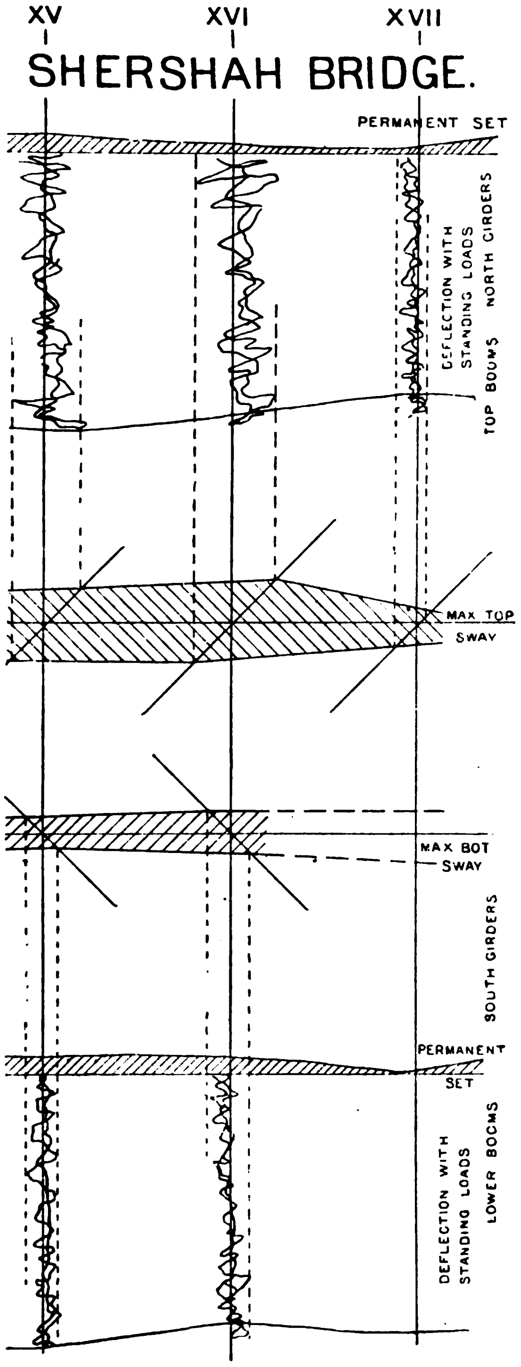
Fig. 2.

DEFLECTIONS OF THE RAILROAD BRIDGE AT SHER SHAH, INDIA.

THE bridge over the Chenab at Sher Shah, India, consists of 17 through spans of steel whipple trusses, 212 feet 6 inches between pier centers. The trusses are 20.6 feet deep, and the weight is about 220 tons per span. The bridge was built in 1888 and 1889, and was tested by trial loads in January, 1890.

The deflection tests were taken with two Kandahar Reserve (L. L.) engines, and a train weighing .85 tons per foot. The maximum deflection was 1 3/16 inches, of which 3/16 remains as permanent set. The maximum oscillation with the above train at between 25 and 30 miles an hour was ⅜ inch for the top and 3/16 inch for the bottom booms. The test diagrams are remarkably uniform and vary but little from the above maxima. One span tested for oscillation by running a crowd of men over it gave a deflection of 3/16 and sway of ⅛ inch on the cards.



With two L. class engines and tenders weighing 134 tons in all, hauling a train that weighs .873 tons per foot run, the maximum live load on any one cross girder is 21 tons; seven other cross girders carry an average live load of 15 tons each, and the rest of the train averages 9 tons per cross girder. The average uniform dead load is 11 tons per bay, and the maximum effects of the live loads above described approximate very close to those of a uniform distributed live load of 13 tons per bay, or 260 tons per span, and the maximum stresses on the main trusses are 6.5 tons in tension, and 6 tons in compression when a wind stress of 21 pounds per square foot is added to the loads stipulated above. A pressure of 21 pounds per foot is considered the highest under which traffic can ever be carried on. The wind bracing of the floor and the lateral connection of the top booms is effected through the cross girders—which are braced to the booms by horizontal gusset plates, and there are no horizontal diagonals whatever. The wind pressure on top booms is transmitted to the floor through the verticals.

The accompanying diagrams shows the deflection cards (natural vertical scale) taken at the 15th, 16th and 17th spans.

The facts given above are from an article in *Indian Engineering*, and the diagram is reproduced from the same publication.

DYNAMITE IN THE WET FOUNDATIONS OF THE LYONS FORTIFICATIONS.*

A BRIEF reference to this subject was made on page 685, Vol. XVI. The description here given from a different source will, it is believed, prove suggestive when similar or varying conditions are met with elsewhere.

Between the Rhone and the Marseilles line in France, the wall of the new Lyons fortifications traverses alluvial lands continually overflowed by the river. The soil is composed of fine clayey sand, very permeable and blackened by infiltrations of water charged with organic matter. Below this clayey bed, extending to an unknown depth, is a layer of round Rhone pebbles, the upper surface of which is in a practically horizontal plane and is covered to a depth of about 6½ feet by a sheet of water which dilutes the clay to a glutinous mud, very difficult to remove with a shovel.

For a proper foundation of the foot wall it was necessary to reach the gravel bed at a mean distance of about 6½ feet below the bottom of the trench.

In a 656 foot section of the foundation that was built by dredging in a closed coffer dam, where the mean depth of excavation was only 2.6 feet, the work took 80 days and cost about 12,000 francs. The principal difficulty was due to the fineness of the clay, which entered with the water through the cracks in the sheeting and refilled the excavation as fast as it could be made. It was, therefore, apparent that the method employed, suitable only for limited depths, would be impracticable for the remaining 426 feet, where the gravel was at a depth of from 5 to 7.25 feet.

To avoid long and costly operations it was determined to build the foundation on concrete arches, the supporting pillars of which should be founded by the dynamite method already used in dry soils, and the first pits were made in a simple and primitive manner to determine the practicability of the method. Experience justified the expectations, and showed that a nest of dynamite cartridge exploded in the midst of clayey mud with the following effect:

First.—To make smooth, walled pits, cylindrical, or slightly conical, truncated, which, for a 100-gramme nest of cartridges, attained a diameter of 3¼ to 5 feet, and a depth equal to the length of the cartridges, diminished about 15 per cent. by the earth falling back into the pit after the explosion.

Second.—To compress the clay so that the walls of the pit remained vertical and hold together long enough after the explosion to permit the entrance of laborers to clean it out.

Third.—To force the water in the clay to such a distance that it could not return for half an hour after the explosion.

From these results the following problems were solved:

First.—To find an easy, rapid process of making a hole to receive the cartridges.

Second.—To calculate the distance within which it would be unsafe to leave tools and platforms during the explosions.

Third.—After the explosions, to rapidly prepare a support for the walls of the pit, so as to permit work in the interior.

Fourth.—To clean out the earth which falls back after an explosion, and carry the bottom of the pit to the solid ground by hand work.

Fifth.—To place concrete in the excavations.

These problems were solved and the work conducted as follows: The cartridge holes were made by a special mine auger, consisting of a pointed iron cylinder 2 feet 9 inches in diameter, with tempered steel blades attached for about 8 inches from its extremity. This tube was fixed to tubular lengthening bars about 1¾ inches in diameter and 3 feet 3 inches long, connected by sleeves. Borings to the gravel bed were made in two or three minutes by four men, who withdrew the auger and inserted cartridges in the hole. The cartridges contained 100 grammes each of dynamite and were attached, about 5 inches apart, to a wooden rod. Materials and tools were removed about 16 feet before the explosion. The explosion produced very little spoil, the effect of the dynamite being to compress the circumference of the boring without detaching any material from it. At the top of the hole only, the resistance being less, the earth was torn off, thrown upwards, and portions of it fell back into the pit. This action produced a cylindro-conical hole, about 15 per cent. of the total depth of which was filled by the loose earth which fell back. The mean diameter of the pits was about 3 feet 7 inches.

Immediately after the explosion two men placed in the pit a cylindrical drum about 4 feet 6 inches long, 3 feet 7 inches in diameter, made of ⅛-inch sheet iron, furnished with holes in the upper part to receive the withdrawing handles. This drum was sunk and put in place by blows from an iron ram, and a man descended into the interior and rapidly removed the bed of mud above the gravel, two other men forcing the drum further down, while a fourth laborer removed the spoil from the top of the pit. The interior labor, slow on account of the consistency of the mud, only occupied about half an hour, during which time the water, forced back by the explosion to a considerable distance in the earth and there retained by the compression of the walls, did not interfere with the work. It did not even appear until the gravel bed was pierced, when a jet was produced that by its violence soon stopped the excavating; but by this time the gravel was laid bare, or if a little mud remained above it the amount was insignificant, and it could be removed by rapidly pumping out the water, which held it in suspension.

When the depth of the pit exceeded 5 feet the top was enlarged enough to prevent caving in, and the same length of drum used in the bottom In such case, after the drum was removed and the concrete had set, it was necessary to fill in the conical space around the top with gravel well consolidated with the adjacent earth. When the pits were finished the drums were filled half full of concrete, and removed after that had set.

The removal of the drums was at first difficult on account of the friction of the soil and adhesion of the beton, and while the concrete was being placed a trestle was put over the pit and from it the drum was raised by a three-ton tackle in stages of about 20 inches to permit the addition of successive layers of concrete.

The foundation pits were about 20 feet apart, and four skilled laborers could bore and fill five of them, each 6½ feet deep, in ten hours. The construction of the arches, although partly in water, was easy. Beton skew backs were made on the foundation pillars and connected by a concrete arch, laid on a well rammed bed of gravel and with gravel filling at the sides to receive any lime filtrations before the concrete set. Concrete foundations were thus made for a wall 427 feet long, 20 feet high and four feet wide at the base, with an external batter of 2 feet and weighing about 8,530 pounds per foot. Each concrete foundation pillar sustained a load of about 84 tons, and ten months after being constructed no settlements or cracks were visible.

Although the depth attained by the pits did not exceed about 7 feet the results indicate that a depth of 25 feet may be reached by this method, this being the limiting depth that the boring, the most difficult operation, can be effected by four or eight men with a mine auger. The sheet-iron drums can be made up to 20 feet in length by adding on short sections; beyond this length it is difficult to handle them.

Dynamite, in exploding, exerts a nearly uniform force in all directions, whatever the nature of the surrounding bodies. This is exemplified by the curious experiment of suspending a ¼-inch sheet-iron plate by a fine thread and exploding a 50-gramme cartridge upon it. A hole will be pierced through the plate without breaking the thread, or causing more than a slight oscillation of the plate.

The action of dynamite is twofold; a force due to the decomposition and violent separation of the elements of the nitro-glycerine, and the explosion of gas formed by new compounds. The first effect is the most important, and is the chief factor in making the pits; the second explosion tears the surface of the pits, especially near the top, and throws the material out vertically to fall back into the hole.

Exact calculations by M. Bonnefont have shown that the dynamite foundations of a mean depth of 50 feet cost 16.87 francs per meter (about $1.05 per lineal foot), as compared with a cost, under the parallel conditions, of 65.4 francs per meter, when cofferdams and dredging were used.

---

* Translated from an article by M. Bonnefont, published in the *Revue du Genie* and reprinted in the *Revue Industrielle*.

A NEW METHOD OF CLEANING RESERVOIRS.

In The Engineering and Building Record of June 14. a brief reference was made to the arrangement which will be adopted to clear the reservoir at Denver, Col., from sediment in case of necessity. The bottom of the reservoir, as there stated, will be made to form several large pockets at the lowest points in which will be located blow-off valves through which water and any sediment which may have collected may be discharged to any convenient point.

The general arrangement of these pockets and valves is shown in the accompanying illustration, prepared from a photograph of one of the seven reservoirs at Florence, Neb., which supply water to the city of Omaha. The photograph and data were kindly furnished by Mr. W. A. Underwood, of the American Water-Works Company of New York, who in this instance, as well as in the case of Denver, carried out the work.

The formation of the pockets in the bed of the reservoir is clearly shown in the illustration and requires no explanation. The blow-off valves are of the disk pattern and are operated from small hydraulic cylinders arranged in the manner shown, the valve stems in each case being continuations of the piston rods worked from the cylinders. Water under pressure is supplied underneath the pistons by the pipes shown running along the reservoir bed, and the cylinders and pistons are so proportioned for the available pressure that when the water is admitted the total pressure under the pistons is sufficient to raise the blow-off valves from their seats and allow the escape of water and mud from the reservoir. From each blow-off valve opening a 24-inch pipe runs down vertically 15 feet, connecting with the main discharge pipe. The arrangement, it is understood, has been found to work in an altogether satisfactory manner. Where the entire contents of a reservoir are blown off in this way any remaining sludge may be washed off with a jet from a hose.

This hydraulic valve arrangement, according to Mr. Underwood, is in some places used by them on different points on delivery mains for shutting off the water supply when necessary, water under pressure in such a case being admitted to the top of the cylinder. Ordinary gate valves are in such cases employed, the advantages claimed being rapidity of closing and freedom from the danger of twisting the valve stems, incurred by lack of caution on the part of the men in working the shut-off valves in the ordinary way, there being generally a tendency to give the valve stem an extra, though unnecessary, turn, to make sure that a valve is tightly closed. With the hydraulic cylinder attachment the valve is closed by direct pressure, there being no turning of the valve stem, and the water to work the appliance may be taken directly from the delivery main at a point in front of the shut-off valve, the supply to the cylinder being controlled by a cock. Each hydraulic cylinder, it will be understood, is provided with proper discharge openings at top and bottom for the water after it has performed its work in opening or closing a valve.

BOOK NOTICES.

The Electric Railway of To-Day; by H. B. Prindle; 56 pages; published by E. B. Stillings & Co., Boston, Mass.; price 50 cents.

The author explains in the preface that his aim has been to describe the electric railroad system in such language that the reader, who is unfamiliar with technical terms, can readily understand the construction of the apparatus, and the functions of the various appliances used in the electrical propulsion of street cars. To this there is little to be added. The little book is eminently of a popular science character, but will, nevertheless, prove of interest to the engineering student also, giving, as it does, a brief, though necessarily incomplete, resumé of the subject. Several forms of dynamo and electric motor are shown, and illustrations are given of the customary forms of overhead construction. The storage battery system, however, comes in for but slight consideration, and might have been dealt with more fully to advantage.

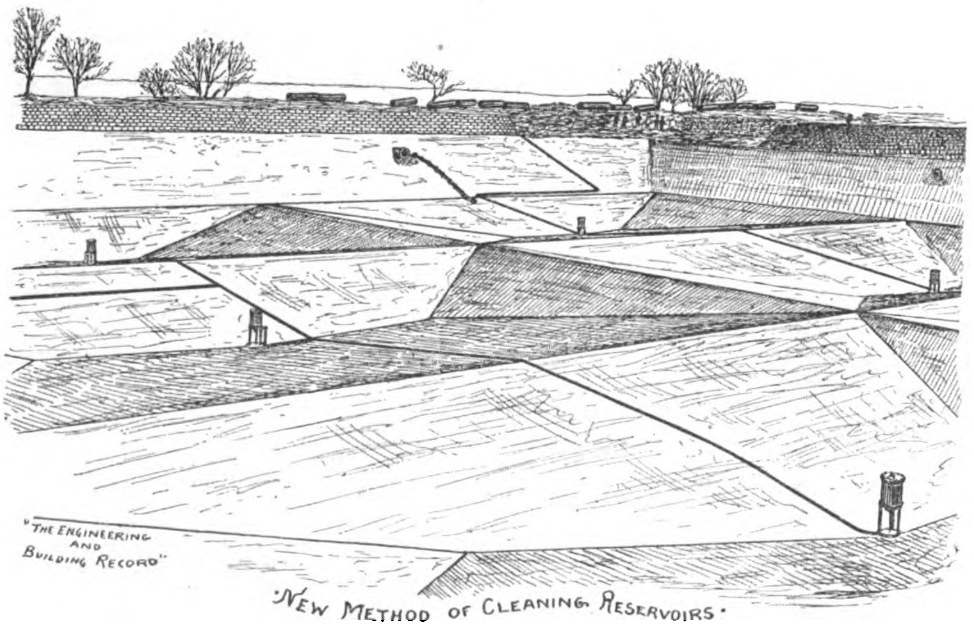
Report of the Board of Water Commissioners of the Town of Needham, Mass., on Water Supply; May, 1890.

On November 7, 1889, the town of Needham, Mass., voted to supply itself with water, and a board of water commissioners was elected. In the report just issued an account is given of what was done, with the view of contracting with one of several adjacent towns for a water supply, and the reasons are given for the conclusion to recommend an independent system of supply. The report of Louis E. Hawes, whose services as Engineer of the Water Board were secured, takes up the greater part of the pamphlet. Mr. Hawes in this report refers at length to the surveys and investigations made by him for the purpose of ascertaining a suitable source of supply, and submits a design for a proposed system of distribution and fire protection, together with estimate of cost and other details.

NEW PUMPING STATION AT BERCY, PARIS.*

The present notice deals with the pumping station from which the Montmartre reservoirs are supplied. The water is taken from the Seine by means of two syphons of cast-iron, which deliver it at the pumping station in wells whose floor is 13 feet 1½ inches below the normal river level. Provision is made for emptying and cleaning the syphons, and, by means of small pipes connecting the highest points of them to the pump barrels, all accumulation of air is prevented. The water is raised from these wells by vertical pumps to cisterns about the level of the highest floods of the Seine, and from these cisterns the horizontal pressure pumps are supplied. The head of water with mean river level is 184 feet in all. The capacity of the pumps in ordinary working is over 11,000,000 gallons per day. There are four sets of pumps, one vertical and one horizontal forming a set driven by one engine. Each engine is of 150 horse-power effective, and is of the Wheelock type with plane balanced sides. Each can act independently of or in combination with any other. The steam cylinder is of 31½ inches diameter. the horizontal plunger 16⅛ inches, the vertical piston 39¾ inches. The steam piston and horizontal plunger have a common stroke of 63 inches. The number of revolutions is 22½ per minute. The site being made on ground overlying peaty mud, the foundations were piled and a masonry floor 3 feet 3 inches thick laid over the whole site, in which the pile heads were buried. There are eight water tube boilers in four groups of two each. The tubes are 4⅜ inches in diameter and 15 feet long, with heating surface of 1,076 square feet, and grate 5 feet 5 inches by 4 feet 2 inches. The boilers work at 85 pounds, and can supply each 4,000 pounds of steam per hour. Six will supply the engines, leaving two for cleaning and repairs.

There are two pressure mains, each 23½ inches in diameter and about 3¾ miles in length. The cost of the works, not including land, was £36,000, or £60 per horse-power measured by water raised. The works were commenced in July, 1887, and the first engines started in May, 1889.



"The Engineering and Building Record"

New Method of Cleaning Reservoirs.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

REPAIRS TO MACADAM ROADS.

Essex County Engineer's Office,
Newark, N. J., June 20, 1890.

To the Editor of The Engineering and Building Record:

Sir: In the diffusion of valuable information on the road question by your paper there are one or two points on which I am at variance with the accepted methods in the way of road repairs, and on which it would seem proper to make a few remarks based on practical experience. The divergence is mainly on three points:

First.—I do not patch.

Second.—I do not use steam rollers.

Third.—I do not use screenings.

First.—On the advisability of patching. All treatises, books and articles written on roads lay it down as a fundamental principle that on the proper and systematic repair of roads a force of men should be continually kept at work patching up, filling holes and repairing bad spots in the roads. In my practice I have avoided this as much as possible. In the first place it is desirable to build your road at first so that it may wear down uniformly. If this is done patching is unnecessary, and when the road wants repairing or renewing, as undoubtedly it will, make the repairs in stretches of a mile or two miles at a time. If these repairs or renewals are thorough the process can be renewed at proper intervals, *ad infin.* To quote an old saying, a patch on the clothes is premeditated property, so patching roads is premeditated negligence or ignorance. Of course to achieve such a non-patching result proper care must be taken in the first construction, and still greater care in the subsequent renewals.

Second.—As to the use of steam rollers. The only real argument to be used in favor of a steam roller is that it is more economical to move a roller of 15 to 20 tons weight by steam than by horse power. This I freely grant, but at this point all comparisons cease. I think better results can be gained by running a horse roller over a stretch of newly-laid stone, weighing two tons, 15 times, than from a 15-ton roller twice, the hauling in these cases being the same, the constant trituration, if I may so call it, being of far more efficacy than the dead weight occasionally applied. The great objection to steam rollers is that they make a practical embargo on all travel during their use, and, while in the construction of new roads this may not be objectionable, in the repairs of roads it is, in the language of the vernacular, a tremendous nuisance. In addition to this the concentrated load of 300 pounds per square foot, which a steam roller occasions, is very trying and somewhat destructive to bridges, culverts and pipes, which of necessity must exist on long stretches of road.

Third.—As to screenings. While not condemning absolutely the use of such material, I consider it a luxury and not consistent with the economical maintenance of roads. If placed on a road in dry weather with heavy travel it lasts from four to six weeks and is then *non est.* In criticising these points it will probably be in order for me to state what substitutes I use in their place, and to do this I will briefly state the practice of road repairs as crystalized by my experience. In Essex County we have about 40 miles of county roads. These roads are arterial, being the main conduits of travel for a population of 250,000 people, excepting the pure intermural travel of the city of Newark. To keep these in repair the sum of $25,000 is annually appropriated; of this amount about $17,500 is spent in repairs of the pavement, the rest for gutters and sidewalks. This would place the cost of repairs of pavement at about $450 per mile, or nearly 4 cents per square yard, the pavements being 20 feet wide.

The practical working of the repair system is as follows: In the spring of the year bids are received from responsible, experienced men, for teams, carts and men per day, and the work is given out to these parties, and they are assigned to the different avenues.

Bids are also received for broken stone, 1½ inches in diameter, per long ton, delivered and dumped at the required spot on the avenue. These prices are for the year. The stone is delivered, the weigh bill punched, and the bill paid on the evidence of the punched weigh bill. When the stone is deposited the spreader spreads it uniformly along the surface of the road. One of the secrets of success in repairs depends on the ability of the spreader. He is like the poet, *nascitur non fit.* You may try a hundred men and only find one spreader, and when you find him, keep him. When the stone is spread it is rolled with a 2-ton horse roller, until the surface is fairly smooth. Then a coating or packing of loam or clay is put on, of a thickness of about ¾ inch to 1 inch This is then rolled for, say half a day, with the same roller, and the general travel allowed immediately to come upon it. The result is at first ruts and unevenness, but with careful watching and rolling, interspersed with occasional hand leveling, the surface, in about three days, will have come down to the desired uniformity and is then left to its fate. Occasionally, in very dry weather, more packing will have to be put on, or in very wet weather, more rolling and leveling will have to be done, but the whole manner of treatment has to be arranged according to the conditions of weather present and prospective and the class of travel coming on the road. No cast-iron rule can be observed, and successful results are only attained by good judgment and experience.

---

* A paper by R. Andra in *Le Génie Civil*, abstracted in Excerpt Minutes of Proceedings of the Institution of Civil Engineers.

The only location whereon screenings are used is on the heavy grades down the mountains. It has been found that during the windy weather in the month of May, some protection has to be placed on the roads to keep them from breaking, so on the mountain slopes we place a layer of screenings, and on the rest of the roads, if their symptoms are bad, we sprinkle a light coat of loam to tide them over the dry, windy weather. This sprinkling of loam costs about $30 a mile, and I find it is impossible to get along without it and have good results. The coat of screening costs from $300 to $400; about as much as the average cost of renewals.

There are two points of special import that I wish to allude to, and that is for good, sound, economical results, broken stone of the size of 1½ inch is proper, and also that the Orange Mountain trap has better qualities for road making than any of the Bergen Hill or Palisade traps. This I do not state from prejudice, but from long experience in both kinds.

Feeling somewhat lonely in my experience on road repairs I have made occasional trips to New York City to observe their practice there, and after the observations I see no need to change my views. In the repairs of St. Nicholas Avenue I was much struck with the *modus operandi*. First a block of one-half the street is fenced off, into which the steam roller is corraled. Then two policemen are detailed to care for the fretful horses stirred up by the snorting and puffing of the steam, and occasionally a mounted policeman is detailed to help the others, and the roller puffs up and down its isolated block scrunching stone of sizes as big as your fist to that of a hickory nut, to a uniform surface and on top of which is spread a coating of screenings thick enough to stand alone. The whole process seemed to me barbarous and extravagant and certainly nothing that could be advantageously copied by any other community.

I then visited the Boulevard and found its condition hardly up to par. Humps and hollows existed in plenitude, and it was far from being a model road. So I returned to Jersey, feeling that even if isolated and at variance sufficient inducement had not yet been offered for me to mingle with the large army of road patchers.

JAMES OWEN.

[Discussions on practice and experience in road building and maintenance are always welcome in these columns, and we invite our readers to discuss the points made by Mr. Owen. Meanwhile we would say that from our experience the effect of the presence of a steam roller on horses is rather over-stated in Mr. Owen's communication. Horses get used to them as they do to other objects that, when strange, frighten them.]

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department*. Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

AUTOMATIC REGULATING VALVE FOR WATER MAINS.

"INQUIRER," St. Johns, N. Y., writes: "In a recent number of *Engineering* there is a brief reference to an automatic regulating valve to be used on water mains to reduce or regulate the pressure. It is the invention of an engineer, Mr. William Key. It is described as being worked in such a way that the pressure can be reduced to any desired extent, but in the event of a fire breaking out the pressure can immediately be raised to its full normal extent. Such a valve would doubtless be very useful in many cities. Could you kindly inform me if it has been adopted anywhere, and has it been a practical success?"

[In the copy of *Engineering* referred to, for January 31, 1890, no descriptive particulars of the valve are given, and we are not acquainted with its character. Regulating valves of various kinds, enabling the pressure in a pipe system to be quickly increased to any reasonable figure desired, are in current use, and, so far as we are aware, have practically demonstrated their value in fire-pipe systems. The reduction of pressure, to which our correspondent refers, is very probably effected by throttling the supply, the valve being opened wide when full pressure is wanted. We should be pleased to hear from any one who may know of the particular valve in question]

VENTILATING MANHOLES WITH CHARCOAL POCKET.

EDWARD MOHUN, of Vancouver, B. C., writes: "In your issue of the 31st of May, page 411, is an article, descriptive, as I understand it, of what is claimed to be a new design for the ventilation of sewer manholes.

The use of charcoal in a precisely similar manner to that explained in your paper is referred to, with explanatory drawings, on page 12 of Sir Robert Rawlinson's 'Suggestions,' revised and published in 1878.

I am not quite certain, speaking from memory, but think it is to Mr. Baldwin Latham that we are indebted for the spiral charcoal tray to be placed in manholes or ventilators for the attainment of the same object."

[We were aware that this idea of ventilating manholes was not new, but we believe the details of the device shown were of sufficient novelty to be noticed in our Novelty Column.]

OBSERVATIONS AND EXPERIENCES OF SUBSOIL WATERS.*

THESE observations were made in continuation of previous observations on the Bilin chalybeate springs, with a view to a knowledge of the nature of subsoil waters generally. Such waters, it is stated, are met with not only as underground lakes, but as running streams, which follow generally the laws applicable to all rivers and streams—the conditions being, however, in some respects distorted or modified, especially as regards frictional resistance and velocity. For although 6½ to 10 feet per second may not be regarded as an unusual velocity for rivers, it might take underground streams an hour to travel over the same distance, thus showing a velocity 3,600 times less; yet, on the other hand, subsoil waters are sometimes met with having a fall of 1 in 20, or 1 in 16—that is, considerably greater than that of rivers in general. And again, as regards backwaters, and the heading-up due to banks or weirs, these subsoil streams are subject to the same laws as rivers; but the most interesting property of subsoil waters in general is that there is no chemical homogeneity in them; the waters consisting, in fact, of separate filaments of different chemical composition due to outside influences. In this respect, however, similar results are to be observed in large rivers; for example, the flow of the river Inn into the Danube affects the character of the latter river for many miles; and the Moldau at Prague is another prominent instance, for the water of this river, at different points, is of different chemical composition, that along the right bank being much softer than that along the left bank, and the upper layers of water softer than those deeper down. Under the author's surperintendence a boring was made at Bilin through diluvium, chalk and gneiss down to a depth of 426 feet, when an abundance of good mineral water was obtained, the yield increasing with the depth. The rise of the water in the bore shaft was measured automatically, and its curve graphically shown—the time giving the abscissa, and the rise during that time the ordinate. This curve was a regular parabola, showing that the rise was uniform, and not affected by feeders under different pressures; between 380 and 426 feet of depth the curve was stationary, showing that no new springs had been met with. Wishing to tap this chalybeate spring, and to lead it to the sloping ground surface, a tunnel was being driven in the chalk towards the bore shaft, when fresh water was struck of a different chemical composition to the Bilin mineral water, and it was at the same time observed that the surface of the water in the bore shaft was steadily sinking, showing clearly a connection between the chalybeate water deep down in the gneiss and the subsoil stream in the chalk, flowing at a depth of only 15 to 20 feet below the ground surface, and also explaining why other wells that had been sunk above the trial boring showed different water levels. The results of the author's observations and experiences of subsoil waters generally led him to consider the question of the water supply of Prague, which is now very deficient, being restricted to house wells and the filtered water of the Moldau. A project has been under consideration for years past, and trial borings have been made, and the water levels in each well observed; these have shown a very great difference in the degrees of hardness of the water, though all the borings were apparently made in a connected subsoil area; and further experiments proved that the water at the left bank of the subsoil stream was considerably harder than towards the center. This hard water, it was thought, might be due to the supply coming through chalk strata, and the varying degree of hardness owing to the deposit of carbonate of lime in passage through the earth; but it is stated that the amount of hard water met with is entirely disproportionate to the amount of rainfall in the particular locality, and that the subsoil streams at Prague lie deep down in the earth, and are of different chemical composition. These considerations, it is stated, did not furnish much light on the question of deep boring at Teplitz, where there are subsoil warm springs, of volcanic origin, extending over a large and deep lying subsoil area, and where deep boring is of advantage, but the observations on the Bilin chalybeate springs prove that subsoil waters really play an important role in the province of medicinal waters, which has been hitherto ascribed to volcanic origin.

DOMESTIC PLUMBING HEATING LIGHTING & VENTILATION ENGINEERING

CONVENTION OF THE NATIONAL ASSOCIATION OF MASTER PLUMBERS.

(From our Special Correspondent.)

DENVER, COL., June 19.

TUESDAY'S SESSION.

THE National Association of Master Plumbers of the United States opened its eighth annual convention in the Chamber of Commerce here at 2 o'clock P. M. Tuesday, June 17. President Hannan called the convention to order, and addresses of welcome were made by M. A. Dolan, President of the Denver Association of Plumbers, and Wolfe Londoner, Mayor of the city.

President Hannan responded in a few words, and announced that the first business in order was the appointment of a committee on credentials.

On motion of William Harkness, Jr., of Philadelphia, the chair appointed as such committee, William Harkness, Jr., of Philadelphia, James Foley, of Kansas, and Dan Shannon, of Boston, who, with Secretary Green and Secretary Sheehan, should examine and report on the credentials of the delegates.

The Secretary read the following telegram:

NORFOLK, June 17, 1890.

Virginia sends greeting, invokes harmony and much pleasure to all, ladies included. W. E. FOSTER.

After the reading of this telegram the convention took a recess to witness the operations of the Denver Fire Department.

On reassembling the Committee on Credentials submitted the following report:

Your Committee on Credentials present the following as their report: Number of States represented, 19; number of cities represented, 37; number of delegates as per credentials, 180; and we herewith attach a list of delegates. Respectfully submitted.

WILLIAM HARKNESS, Jr., *Chairman.*
JAMES FOLEY.
DANIEL SHANNON.

Baltimore, Md.—P. T. Barry, James Healy, William Drusnett, John Trainor, W. W. Rowles, Joseph C. Mitchell.

Boston, Mass.—I. J. Tute, William Lamb, Daniel G. Finnerty, Daniel Shannon, W. H. French, Henry W. Toombs, D. A. Hogan, Joseph H. Bagley, David Smith, J. F. Cronin, W. H. Mitchell, William McKenna.

Bridgeport, Conn.—H. B. Middlebrooks, Alfred Hopkins, L. H. Mills.

Brooklyn, N. Y.—George B. Lewis, William Fallon, George Cummings, H. H. Noble, T. W. Kelly, M. J. Lyons, Thomas Hudson, William J. Fitzpatrick, Theodore Radcliffe, John J. Keenan, Paul Ayres.

Buffalo, N. Y.—L. P. Beyer, Charles Geiger, Fred. Yuhl, C. H. Carey, Jacob Mensch.

Burlington, Iowa.—Henry Ewinger.

Chicago, Ill.—H. Watt, R. Griffith, D. Whiteford, J. H. De Veney, M. H. Reilly, C. J. Herbert, H. J. Kilrain, William Bowden, J. H. Roche, J. R. Alcock, C. J. Byrnes, C. C. Breyer, D. J. Rock, A. Young, T. F. Gay, J. J. Hamblin, J. G. Weber.

Cincinnati, O.—John A. Douglas, W. F. Wagner, Richard Murphy.

Cleveland, O.—C. C. Dewstoe, W. A. Kelley, J. Schneeberger.

Colorado Springs, Col.—E. S. Bunstead.

Columbus, O.—E. A. Futerer, C. A. Klie.

Decatur, Ill.—Philip Mueller.

Des Moines, Iowa.—Joseph Laing, John Burnside.

Duluth, Minn.—W. H. Dwyer.

Glenwood Springs, Col.—Joseph A. J. Clouden.

Indinnapolis, Ind.—John S. Farrell, Peter J. Gall.

Kansas City, Mo.—L. B. Cross, Alexander Gray, H. B. Farley, Dell Guay, R. B. Farley.

Kansas State Association.—James Foley, S. J. Stewart, Thomas Lloyd, C. J. Prescott, R. Wood.

Lowell, Mass.—Thomas Costillo.

Leadville, Col.—C. N. Priddy.

Minneapolis, Minn.—E. C. Couvet, A. W. Scott.

Milwaukee, Wis.—Charles Foleshek, W. E. Goodman, Herman Appell.

Nebraska State Association.—J. H. O'Neill, M. A. Free, N. B. Hussey.

New York City.—Joseph A. Macdonald, George D. Scott, J. N. Knight, William R. Brocken, H. G. Gabay, William P. Austin, F. Sullivan, James Gilroy, D. Mackay, Jr., I. J. Toumey, C. Fraser, P. J. Cummings, Frank Reynolds, William Young, E. J. Brady, W. H. Quick, J. W. O'Brien, D. W. Littell, George B. Brown, Philip Smith.

Philadelphia, Pa.—John E. Eyanson, William Harkness, Jr., Enoch Remick, William W. Wright, W. H. Doyle, F. P. Brown, J. J. Weaver, George F. Uber, A. G. Bond, William McCoach.

Portland, Ore.—I. J. Johnston, J. J. Owens, Alexander Muirhead.

Pueblo, Col.—E. P. Fish, C. Geiser.

Pittsburg, Pa.—J. J. Kennedy, B. F. Call, James McGinness, Frank McKnight, Leo McShane, Allen McFadden, George Sands.

Rochester, N. Y.—J. H. Howe, William Barr, I W. Ford, W. G. Reid.

Sioux City, Iowa.—D. W. Fitts, John F. Gearen.

Springfield, Mo.—W. W. Cronin, Harry Cooper.

St. Louis, Mo.—F. Abel, J. Sheehan, Joseph Funalty, William H. Graham, Joseph P. Gallagher, David Roden, Thomas Cantwell, Samuel S. Doony, Edward P. Rearden, P. C. Ring, M. J. Ward, Joseph A Stedger, William Morris, James A. Lynch.

St. Paul, Minn.—J. J. Dunnigan, J. P. Adamson, P. W. Hudner.

St. Joseph, Mo.—R. F. Connell, M. E. Herbert.

Syracuse, N. Y.—R. C. Maclure, Edward Jay, Alfred Tilley

Salt Lake, Utah.—J. J. Farrell, H. C. James.

Washington, D. C.—James Rogan, Edward J. Hannan, George A. Green, Joseph Lockhead, George Hutchins.

Wilmington, Del.—Alfred Gawthrop, Thomas Reilly.

Davenport, Iowa.—James Cameron.

Denver, Col.—N. A. Dolau, W. H. McCarthy, W. F. Brane, Daniel F. Frey, W. F. McCarthy, James Shannon.

Lowell, Mass.—Thomas Costello.

Bloomington, Ill.—Robert Landen.

Hornsburg, Pa.—John A. Kromer.

The report of the Committee on Credentials was adopted.

W. H. McCarthy, of Denver, was appointed sergeant-at-arms, and Henry G. Gabay, of New York, was appointed assistant secretary.

George Sands, Pittsburg; Henry W. Toombs, Boston, and Peter J. Gall, Indianapolis, were appointed auditing committee.

The following communications were read and the secretary instructed to acknowledge receipt:

FORT WAYNE, IND.

Sorry I could not attend, but wish you a harmonious and successful convention and pleasant time.

JAMES MADDEN.

CITY OF CHICAGO,
HEALTH DEPARTMENT.

This is to certify that I have appointed Mr. Andrew Young to represent the Health Department of Chicago at your convention.

SWAIN WICKERSHAM,
Commissioner of Health.

The convention then adjourned to 9 o'clock Wednesday morning.

In the evening a ball was given at the Chamber of Commerce in honor of the delegates and their ladies.

WEDNESDAY MORNING SESSION.

The convention was called to order at 9 o'clock Wednesday morning, and, in the absence of Secretary Green, W. H. Mitchell was chosen Secretary *pro tem.*

The report of the Essay Committee, A. W. Murray, Chairman, was read as follows:

CHICAGO, June 14, 1890.

The accompanying printed report explains the work of your Essay Committee, and hoping for the continued prosperity of the organization, we beg to subscribe ourselves your obedient servants,

ALEXANDER W. MURRAY,
M. L. MANDABLE,
C. J. BROOKS,
FRANK E. RUH,
P. J. LOUGHLIN.

CHICAGO, ILL., February 25, 1890.

E. J. HANNAN, Esq., *President of the National Association of Master Plumbers, Washington, D. C.*

Your committee on announcing subjects for essays for the Denver convention, beg leave to report as follows:

1. The exhibition of plumbing materials and workmanship at the World's Fair in 1892. What method can be adopted to make it an attractive feature and of general benefit to the plumbing interests.
2. Electricity in the plumbing trade. (*a*) Applications. (*b*) Dangers to workmen from electric wires.
3. Automatic flushing apparatus, and their application to plumbing fixtures.
4. Air currents in the interior of a building. (*a*) Motive power causing them. (*b*) In what manner contaminated. (*c*) Their influence on the seals of traps.
5. The proper system for controlling the water supply of buildings in cold climates.
6. The best system of preventing back-water from sewers entering buildings during severe rain storms.
7. Management of a plumbing establishment. (*a*) The office. (*b*) The salesroom. (*c*) The workshop. (*d*) Arrangement of stock.
8. Water-backs for heating water. (*a*) What metal is the best for its manufacture. (*b*) Care necessary to prevent explosion. (*c*) Cause of explosions.
9. Inspection of plumbing and house drainage. (*a*) Benefits to householder. (*b*) Benefits to plumbing interests.
10. Water filters. (*a*) What is the best for domestic use. (*b*) Quality and kind of filtering material generally used.
11. Progress of sanitary legislation. (*a*) Method to adopt in obtaining favorable laws from legislative bodies. (*b*) Example of a proper law.
12. Traps, and what is known of them as at present used in the plumbing trade.
13. How to promote larger attendance at local association meetings,
14. The principles of natural philosophy in the sanitary appliances of a building. (*a*) Is there any other business where the practical use of these principles is in greater demand than in household sanitation?
15. Is competition in plumbing to the best interests of the householder?

All of which is respectfully submitted.

ALEXANDER W. MURRAY,
M. L. MANDABLE,
C. J. BROOKS,
FRANK E. RUH,
P. J. LOUGHLIN.

NATIONAL ASSOCIATION OF MASTER
PLUMBERS OF THE UNITED STATES.
OFFICE, 517 ELEVENTH STREET., N. W.,
WASHINGTON, D. C.

To the Master Plumbers of the United States, in affiliation with the National Association, greeting.

The Committee on Essays having selected the inclosed subject for essays, to be prepared for our coming convention, which will be held in Denver, Col., June 17, 18 and 19 next, and believing that it is better that each subject be assigned to a local association, we therefore request the co-operation of the presidents by the appointment of members to write upon the subject assigned to their association, selecting the best and having the same printed and retained until read before the convention, and afterwards distributed. We wish it understood, however, that while we assign each subject to a particular association, members of other associations are not debarred from writing upon the same subject, but their contributions are invited.

First—To Chicago Association.
Second—To New York Association.
Third—To Buffalo Association.
Fourth—To Milwaukee Association.
Fifth—To St. Paul Association.
Sixth—To St. Louis Association.
Seventh—To Omaha Association.
Eighth—To Baltimore Association.
Ninth—To Philadelphia Association.
Tenth—To Brooklyn Association.
Eleventh—To Boston Association.
Twelfth—To Kansas City Association.
Thirteenth—To Kansas State Association.
Fourteenth—To Cincinnati Association.
Fifteenth—To Colorado State Association.

Very truly yours,
EDWARD J. HANNAN, *President.*
GEORGE A. GREEN, *Secretary.*

The report of the committee was unanimously adopted.

The Apprentice Committee submitted the following report, which, after a spirited debate, was adopted:

The apprentice question of to-day is one of the most important that we have to discuss at our annual conventions. What the foundation is to the building, what seed grain is to the farmer, the apprentice is to the plumbing profession.

The trade has in the past employed boys to learn the business without regard to their mechanical ability or tastes; the result has been that 50 per cent. of them quit work or were laid off in one or two years, being entirely unfit for the trade, and only 25 per cent. of the total number employed became first-class plumbers. We must put better material into our shops in the future if we expect to make perfect plumbers.

A few years ago apprentices in England and other European countries were required to serve seven years, and then often had to pay for the privilege. When they got through they were finished mechanics, if not artists. Many of them, coming to this country, could shape anything out of lead.

The average time for an apprentice in this country has been five years. Very often boys break through their obligations and quit work, and proclaim to those who employ them that they are journeymen. It does not take long to prove their assertion false; and the result is provoking and expensive, as it frequently happens that they are put on first-class work, which has to be done over. And the trade unions allow these men to select the class or grade of work for themselves, without any regard to their experience or ability, which is a great imposition and outrage on the business. We all have this experience sooner or later. Boys become restless as the end of their apprenticeship approaches, and often demand wages they are not entitled to. They become filled with their own importance, and give a great deal of trouble, often acquiring expensive habits which their limited wages will not keep up.

A case of this kind came up in St. Louis. The boy quit work, and, after several weeks' wandering, found a man who wanted a plumber. He hired as a journeyman, but after a short trial his employer told him he was not a journeyman. The young man acknowledged he was not, and admitted the deception. His employer then made arrangements to employ him for a year under instructions at a small advance over his former wages, and the boy went to work for him. His former employer had some circulars printed, informing the members of the organization that this boy had not finished his apprenticeship, as agreed, and also referring to an article in the by-laws which prohibited any member from employing an apprentice who worked with another member, without his consent. The young man was laid off, and could not get work in any first-class shop in the city. He could go back and finish his apprenticeship, but he got stubborn and refused to do so. He tried to get work under an assumed name, and did get some work in a few small shops, but finally had to leave the city.

He brought suit for $5,000 damages, which was demurred to and the demurrer sustained. Then he amended his petition and sued for $2,500, and his employer set up a demurrer to that also, and it was sustained. The boy's attorney then took it to the Court of Appeals, where they ordered the case to go to trial.

In the meantime, the judge who sustained the demurrer on the two occasions failed to be re-elected and a new judge tried the case. Both parties fought the case zealously, but there was a good common jury trying the case and they gave a verdict against the apprentice and in favor of the employer.

Then the Knights of Labor and other labor organizations raised a howl, claiming to have elected the judge, and that he had made pledges and promises to them. They were furious because the boy lost the case, and were going to have a special law passed in Jefferson City protecting workingmen, etc.

The boy's attorney applied for a new trial; and, after two months' waiting, the judge granted it on the sole ground that the verdict was not in accordance with the evidence.

The employer then took a change of venue, declaring he could not get justice in that court; that he had fairly won the case and it should have gone up to a higher court on its merits. It was assigned to an associate judge of the one before whom it had been tried, who was elected on the same ticket and indorsed by the labor party. This time 10 of the 12 jurors were young men employees, and when they were sworn in we knew the case was lost. The case was discussed by them for two days and they finally brought in a verdict for the boy for a portion of the amount claimed.

The case was appealed. The Court of Appeals confirmed the verdict on the ground that the boy was not indentured according to the law of the State of Missouri, which says that an apprentice must be taken before the Probate Court, accompanied by his parents or guardian and two witnesses, and have a notary certify the papers. It was proved that five years was the customary time for a boy to serve at the business, learning the trade. The court ruled that when there was a written law governing the case custom could not prevail. The boy had been well treated, was paid his wages promptly, and had no other ground for complaint but that he was not legally apprenticed.

An effort was made to take the case to the Supreme Court on constitutional grounds, but the amount sued for limited it to the Court of Appeals. This was the first case of the kind ever tried in the State of Missouri, and it was commented on by the daily press as a case of great interest to employer and employee.

The lesson learned is to take no apprentice unless properly protected by papers. No employer wants to educate a boy and then when he is able to do anything have him quit work, often when he needs his services most. What our trade wants as apprentices is young men about 16 years of age, strong and sound, physically and mentally; boys who are not afraid of work. Reading, writing and arithmetic is all the education they need, with a decided taste for mechanics. If they have not this taste or talent all the education in the universe will not make mechanics of them. Too much education unfits a boy for a trade. It makes him feel that work is degrading, and he wants some work that will not soil his hands.

The trade schools are very popular in New York and Philadelphia. In about three months a boy gets his diploma, and can make a joint, bend a pipe in all sorts of shapes, and solder ends of lead together; all of which does not make a finished workmen by a great deal. If a boy does not work in a shop, in addition to the trade school lessons, the result is superficial and is only a veneering. The promiscuous education of boys, without regard to their talents or tastes for mechanical pursuits, is pernicious, and often ruinous to the boy's future. A boy whom nature intended for a minister or a merchant can never be made a mechanic.

We are not in favor of short methods of education. They are not durable. Nature takes the usual time to perform her work, and it is done well. The earth takes the same time to perform its revolutions. The sun, the stars and the various planets revolve in their endless orbits, and have done so for thousands and thousands of years; they have no short route over which to travel; they go over the same old beaten path. What would the public think if Yale, Harvard and Princeton College were to announce that instead of four years' study, as of old, you could get all the degrees in three months, under the direction and care of old experienced teachers? The people would be astonished and would think it impossible. Does our trade school enthusiast think to overcome the laws of nature by cramming into a boy's brain in three months what it usually takes as many years to accomplish? We admit that as preliminary training for a boy, before going to learn his trade, it is splendid; but of itself alone it will do much harm. "A little learning is a dangerous thing."

Euclid, the world-renowned mathematician was asked by the king to reveal his knowledge to his son, without the drudgery and labor of years' studying to acquire it. The king offered him a large sum of money if he would comply with his request. Euclid said: "Sire, I would do so with pleasure were it not impossible. There is no royal road to knowledge. Your son must study and learn like all the other boys in your dominion."

The same great truth holds good to-day. Look at our successful men in their various pursuits. They were poor boys, who, by untiring exertions, won fame and fortune. Ericsson, Edison, Morse, Carnegie, Fulton and Stephenson—we want a few boys like these in the plumbing business to elevate and ennoble it. Andrew Carnegie says he began in an office using a broom. All boys should begin low and aim high; avoid gambling, drink and other bad habits; and an industrious, persevering boy with good habits can, and does work his way to the head of his profession.

Your committee recommends the trade schools in connection with actual work, as an apprenticeship in a plumbing shop, experience in the shop and technical instruction in the training school combined will make a first-class mechanic of a boy, but trade-school instruction alone will fail to make a finished mechanic.

We request every city and town where there is a plumbers' association to establish and maintain a trade school in connection with their shops, where their apprentices can be instructed in the science of the trade one or two evenings a week, by a committee appointed for that purpose, and to establish a reading room in the same building, if possible. In this way the trade will be kept in its proper channel and diplomas given by veterans in the business to finished plumbers only.

William H. Graham,
James A. Lynch,
Thomas Cantwell,
Committee.

The reports of several State vice-presidents were submitted, after which the convention adjourned until 1.30 P. M.

WEDNESDAY AFTERNOON SESSION.

On reassembling in the afternoon the first business was the address of President Hannan, which was as follows:

Gentlemen: It now becomes my pleasant duty to render an account of my stewardship for the past year. I am happy to inform you that a misunderstanding which existed between a manufacturer and one of our local associations when I was elected has been investigated by a committee of three State vice-presidents appointed by me. After receiving their report, which unanimously sustained our members, the case was amicably settled. Entire harmony prevails between the better class of manufacturers and dealers and the trade. Where there are any violations of our protective resolutions they are on the part of the small, mean tricksters who are compelled to resort to all manner of devices to secure trade. They are engaged in an illegitimate pursuit, pretending to be doing a wholesale business while, in reality, they are retailing. I must confess that in a great many cases the plumber is to blame, for such dealers could not exist long if they depended on their illegitimate trade. Names of those so engaged and details will be given in executive session.

It cannot be denied that to a certain extent we have continued to carry out the objects for which we organize; our special objects being for sanitary, commercial and social purposes. The States and cities having sanitary laws are about equal to the number of associations represented here to-day, which is proof that we have attained the object for which we are banded together, as far as the sanitary feature is concerned. The sanitary laws which are in effect, as well as the vast improvement in the class of work being done at the present time, have been secured through the efforts of our members.

Need I say anything about the social feature? The banquets, balls, excursions and picnics of the past year. which have served to bring our members together, speak for themselves.

We should now turn our attention to the commercial feature, for we have not improved financially in proportion to our advancement in other directions. This is due to the fact that in every community unscrupulous men, who, without mechanical skill or technical ability, are conducting a business and come into competition with respectable, intelligent members of the craft. They receive all the advantages of trade discounts and the benefits of organization, although not affiliated with any association for protective measures. The remedy seems to be found in urging the passage of State sanitary laws to prevent any but competent persons from engaging in the business.

Thanks are due Colonel Richard Auchmutty for inaugurating trade schools, for they are doing an excellent work throughout the country, and they should continue to receive the indorsement of every good and patriotic citizen. Educating the young men, technically and practically, will solve the question of competency.

During the year I traveled about 7,800 miles in the interest of our association. I visited Milwaukee, St. Paul, Minneapolis, Sioux City, Omaha, Chicago, New York, Albany, Rochester and Buffalo. The increase in membership here to day furnish a proof as to whether the time and money were well spent. The receptions given and the treatment received on those occasions more than paid me for the time spent in the interests of our association.

While in Chicago I had the pleasure of meeting the Hon. DeWitt C. Creiger, Mayor of the city, and extending to him the thanks of this association, as passed by vote at the last convention, for appointing our honored Ex-President, Andrew Young, to the position of Chief Sanitary Inspector for Chicago. By so doing he honored our trade and proved our argument that practical men should be appointed on all health boards and as inspectors.

During the year we have organized and received into the National Association eight associations, as follows: Memphis, Tenn.; Duluth, Minn.; Indianapolis, Ind.; Watertown, N. Y.; Birmingham, Ala.; Erie, Pa.; La Crosse, Wis., and Salt Lake City, Utah. In addition, we have received individual members as follows: Texarkana, Ark.; Jacksonville, Fla.; Fargo, N. D.; Barre, Vt.; Portsmouth, N. H., and Huron, S. D. By referring to the Secretary's Report, it will be seen that our membership has increased each year.

The plan of employing an executive clerk I found to be an excellent one, for by so doing I was enabled to answer all correspondence promptly, as well as to send our personal letters to gentlemen in our business who were not members, urging them to organize. If I did not succeed in all cases in getting them to organize and unite with us, I think I have sown seed which may take root and grow under a future administration.

I would urge upon all associations in affiliation with the National the necessity of living up to our constitution and by-laws, and platform of principles, as adopted at Pittsburg.

The success of, and good example set by our association, has been followed by all the building trades, in organizing associations, and the forming of Builders' Exchanges. But we must not let them excel us; neither can they take the place of our organization. I would recommend that our local associations in cities which have no statutes governing plumbing, continue to agitate the question until such laws are enacted; not only for the benefits which they will derive from such legislation, but for the good of the public health.

I know it would be a great tax for my successor to visit our local associations, but much good can be accomplished by a personal visit, especially where differences exist. A visit to the localities which are unorganized would be productive of better results than a year's correspondence.

The national association is not an organization separate from the individual societies—it is an amalgamation of them all. Its direct object is to build up and strengthen every association which enjoys its membership, thereby strengthening itself. New York State by herself would be a small and insignificant nation. Rhode Island would be of less importance still, but as parts of the great American commonwealth each obtains a new power and majesty and acquires a voice in deciding the destinies of the world.

It is very important to know at all times who our members are, and when we receive new ones or any drop out it should be made known either through the trade papers or by circular.

There are a few traitors in our camp who must be sought out and driven from the ranks when found. The time has come when the Executive Committee should be empowered to weed out all such, and to take away the certificate of membership from any association violating our constitution or rules.

I congratulate all the local associations on their progress during the past year. It seems as though all had adopted the motto "Excelsior." I wish to thank the officers of the several associations for their promptness in answering all communications, and their willingness to co-operate with me in advancing the good work of our organization. I also tender my heartfelt thanks to the trade press for the assistance rendered by the willingness to publish all matters of importance.

In conclusion, I desire to thank my colleagues of the Executive Committee for the good advice and assistance rendered me during the year, the successful termination of which has been due to the good will manifested at all times; and I bespeak for my successor that same good will and co-operation on the part of all, in order that his administration may be as successful and his relations as pleasant as mine has been.

Secretary Green submitted his annual report, as follows:

Gentlemen: In submitting my report for the year ending with this convention, I desire to state that the duties of the office have been performed with dispatch and all the correspondence promptly attended to.

I presented a copy of the proceedings of each annual convention to the library of Congress and received therefrom a letter accepting the gift.

During the year there were about 475 personal letters written, 350 circular letters hectographed and sent out, and about 2,000 circulars and 1,800 copies of proceedings of the seventh annual convention distributed.

A few remarks on the growth of our organization might not be out of place at this time. By referring to previous reports of the Financial Secretary it will be seen that in 1884 we had 1,315 members in good standing; 1885, 1,148 members; 1886, 1,188; members; 1887, 1,360 members; 1888, 1,456 members; 1889, 1,526 members, and in 1890, 1,700 members.

I take pleasure in reporting the following additions to our membership during the year:

Memphis, Tenn.—Twelve members, namely: J. A. Bailey & Co., J. W. X. Browne, Bruce Rutledge, Hartie & Scheid, Woods & McGrath, John Hopkins, Rhodes Brothers, Massa Brothers, Leech & McClain, P. Callahan, Lagomarsino & Zanoni, and Latting & Bailey.

Duluth, Minn.—Seven members, namely: William McMillen & Co., Duluth Plumbing Company, N. C. Harvey & Co., P. V. Dwyer & Brothers, Joseph Neil, John P. Wray, and Farrel & Sullivan.

Indianapolis, Ind.—Sixteen members, namely: Freaney Brothers, Charles W. Meihel, Healy & O'Brien, Kalb & Ayers, Anashansel & Strong, Foley Brothers & Co., Dewald & Gall, J. S. Farrell & Co., George W. Keyser, Henry T. Hudson, John C Dunn, Smith & Haslinger, Kirkhoff & Meyer, James McGauley, Schmidt & Gunn, and Peck & Toon.

Watertown, N. Y.—Eight members, namely: D. A. Wait, L. A. Howard, Harbottle & Sons, Beffrey & Mowe, F. B. Devendorf, Howard & Arthur, Bragger & Son, and Wicks, Hughes & Griffith.

Erie, Pa.—Eight members, namely: R. T. Williams & Co., William J. Butler, Miller Brothers, Porsch Brothers, Carey & Campbell, Karch Brothers, Kelly & Baker and James Lumbard.

La Crosse, Wis—Four members, namely: James A. Trane, F. C. Healey, C. A. Krebaum and W. P. Powers & Son.

Birmingham, Ala.—Six members, namely: Robert Knauff, R. W. Gayle, W. H. Franklin, E. C. Worms, C. E. Eckerle and P. Schenssler.

Salt Lake City, Utah.—Ten members, namely: Heesch & Ellerbeck, David James & Co., James J. Farrell & Co., L. H. Dale, A. J. Bomdette & Co., James Fenwick, P. J. Morgan, J. W. Farrell & Co., Salt Lake Construction Company and R. Morrison.

Jacksonville, Fla.—One member, John Eirig.

Texarkana, Ark.—One member, T. E. Walters.

Fargo, N. Dak.—One member, William D. Allen.

Barre, Vt.—One member, L. J. Griffin.

Portsmouth, N. H.—Two members, Robert J. Donnelly and John P. Sweetser.

Huron, S. Dak.—One member, H. D. Brach.

Bridgeport, Conn.—Seventy-eight new members.

Colorado Springs, Col.—Three members, E. S. Burnstead, W. H. D. Morrill and William Scott.

Glenwood Springs, Col.—One member, J. A. I. Claridon.

Leadville, Col.—One member, C. N. Priddy.

Minneapolis, Minn.—Twenty-five members.

Pueblo, Col.—Three members, J. H. Bennett & Co., Morgan Geiser and C. F. Fish & Co.

Making a grand total of 112 new members to date.

In surrendering the office of Secretary, I desire to tender my thanks to all for the kindness of which I was the recipient. Respectfully submitted.

George A. Green, Secretary.

Andrew Young, ex-President of the association, now chief Plumbing Inspector at Chicago, made a report as delegate to the Brooklyn meeting of the American Public Health Association as follows:

Gentlemen: I have the honor to submit to your national convention, assembled at Denver, Col., June 17, 1890, my report as your delegate to the seventeenth annual meeting of the American Public Health Association, convened at Brooklyn, N. Y., October 22, 23, 24 and 25, 1889.

It was gratifying to me to be able to meet this gathering of representative, liberal, public-spirited men, laboring with some sacrifices and encouraging and inspiring enthusiasm in the great cause of public health—engaged in promoting the highest interest of the human race this side the common heritage of us all. We can point to no sublimer incident in all the history of our great country than this assemblage of men gathered together, with no thought of pecuniary reward, to enhance the common welfare of man; to present and discuss the best means of preventing the ravages of disease with its resulting misery and woe. The love of liberty and the blessings of self-government have made patriots of our people, and opportunities have made heroes of our patriots; but here is an association of men loyal to the highest interest of mankind, who have made their own opportunities to serve their fellow men. Their profession has made them philanthropists, and their love for mankind has made them benefactors.

The influence that grows out of this association is extensive, for its membership embraces every section and part of the country. It can be said that in these meetings the United States centers its expert thought, investigations and discoveries; and from this center go out to all parts of the States the aid, strength, moral force, and the collected experience and wisdom of organization. This is a great school of hygiene, and its pupils returned as teachers to our cities, villages and rural districts to continue and further extend the great lessons of preventive medicine. The result is, from this center radiate the influences which become severally potential in the education of the people to a higher plane and a better understanding of the importance and value of hygienic laws. Not only this; the association is annually making most valuable additions to the literature of public medicine, the advancing science of sanitation, and through the limitless circulation of the press this literature is dropped at the cottage and the mansion and along the highways and byways throughout the land. The great need in the progress of sanitary reform is the proper education of the people. They have not yet been educated up to the necessities of hygienic laws. They have not been taught the value of sanitation and the importance of its practical application. But education is progressing in this direction, and while this association has not yet accomplished this great end, it, with similar agencies, is making gratifying progress in this direction.

I found at this meeting an attempt made in the way of sanitary exhibits. It was a rather meager display, yet it is a step in the right direction. There is no greater educator in this work than an exhibition of sanitary appliances. It not only serves as an object lesson to impress important principles in the proper sanitation of dwellings, but it is one of the strongest incentives to improvement and invention that can be given. In this feature I found great room for improvement, but I can see no reason why it cannot be made a most valuable part of the work of the American Public Health Association. I am casting no reflection on the members of this association when I state that they in general are not familiar with the commonest sanitary appliances which are such important quantities in the great problem of sanitation. Their work and knowledge lie in another direction, yet no effort will prove wholly efficient without these sanitary appliances, which not only guard the security of the home but stand as sentinels upon the outer walls of communities. Herein we find the field for the plumber, co-extensive with mankind, enriched and adorned with the fruits of genius, and filled with boundless possibilities. As the hearthstone is the origin of the great thoughts that have revolutionized the world and founded empires and republics, so is the home the birthplace and nursery of that science out of which is to flow the beauty and strength, the happiness and health of a new Eden with its sweet air, glorious sunshine, and pure, refreshing waters. Give us healthful homes and we will give you a nation of strong men and fair women.

This leads me to suggest to you a great service which we, as plumbers, can render the cause of sanitation in its more rapid and effective advancement. We stand nearer the health of the home and the sanitation of man's abode than any others. It is our business to provide the mechanical and scientific agencies to secure the healthfulness of human habitations. We are familiar with all the sanitary appliances that science and genius have produced, and are acquainted with the offices they are designed to fill. No men are so well qualified to give a perfect exhibition of these appliances as the plumbers are, and I offer the suggestion that such an exhibition be made a prominent feature of our annual conventions; and as a means to this end I would recommend that this convention, when the place is selected for holding the next convention, authorize the local association of that place to take charge of such exhibition, and proceed with such arrangements as will result in an exhibition which will be an honor to the association and a benefit to the whole country. Each local association can be instructed to give its aid, and I am sure manufacturers will gladly take part in such an exhibition as it is possible and practical for us to give. The value of such an exhibition has been indorsed by high authority and experience, and we possess the means and qualifications to give the greatest exposition of sanitary appliances the country can afford.

It gives me pleasure to state that I was received by the American Public Health Association most cordially as the representative of the master plumbers, and I was assured of the high value placed upon the plumbing fraternity as an important aid in the advancement of sanitary science. During my stay my observations led me into a comparison of the sanatory and the sanitary sciences, and more particularly of the practicing physician and the plumber. The aim of the one is to cure diseases, that of the other to prevent them. The physician drives to the residence in broadcloth, silk hat and gloves, enters the first door, is shown into the parlor or conducted to the sick chamber, is treated with great consideration and served with the utmost courtesy. Every aid or service that can be commanded is rendered him—all that money can purchase or love and sympathy inspire is placed at the service of the physician. Every effort of the family, of relatives and friends, and even of strangers is given to aid the doctor to soothe and comfort the patient and rebuke the disease. There is nothing in the range of human possibilities ever denied the physician in his efforts to heal the unfortunate sick. How is it with the plumber? He walks to the residence dressed in his greasy overalls and blouse, carrying his bag of tools; he enters at the basement or the servants' room; he receives no welcome, no courtesy, no aid. No part of the resources of the family or friends is given him. The family that stood sympathizingly by the doctor in the luxurious chamber are now in the parlor or at the matinee, while the plumber is in the basement fighting with his skill and scientific knowledge the disease germs invading and threatening the life of the household. And what is the difference between the two? The doctor is called in to cure probably the same disease that the plumber could have prevented; yet the plumber is in a dirty, neglected basement or water closet, and for a meager and grudgingly paid renumeration prevents the sickness and suffering which the doctor seeks to cure for a royal and liberally paid consideration.

But they tell us that the plumber is only a mechanic. If he is a mechanic he has that advantage over the physician, who is not. But is he only a mechanic? He may put in a system of plumbing mechanically perfect in every respect, and yet it would annihilate a family in six months. He could employ only his mechanical skill and ruin the health and destroy the life of a whole city. It is his scientific knowledge that is of value. It is that knowledge which not only makes the healthful home but contributes so largely to the advancement of sanitary intelligence. The physician spends one, two, or at most, three years, probably six months out of each, in the study of his profession, and sets out a full fledged doctor, while the apprentice at plumbing must serve five or seven years. The plumber could acquire the mechanical skill of his trade in a short time, but to gain the scientific knowledge of his profession he must devote two or three times the amount of time in which the doctor is required to gain his knowledge.

They tell us the work of the doctor is intellectual. I cannot reflect in the least on the learning and intellectuality of the noble profession of physicians; but who can stand in the presence of some of our great public buildings and private mansions and say that the agent that planned them, hung their drainage and placed their sanitary fixtures was not intellectual? It is not only the hands but the head of the plumber that places about the home its sanitary safeguards. The plumber is not a machine. He is of necessity an intellectual being with a brain as big as that which directs any art, science or profession we have. Recently I had a talk with the managing editor of the *Sanitary News*, whose correspondence and contributions embrace this whole country and parts of others, and he informed me that of the contributions to his journal, and, as he believed, to the general literature of sanitary science, those from plumbers were superior, and the most important means for the promulgation of sanitary knowledge.

Encouragement in our work comes from every hand, as we have much cause to continue our efforts and advance our cause. Let us continue to make healthful homes and public health will follow. In this broad, bounding, youthful land of ours there 6,000,000 homes. Let us make these homes healthful and happy and we will make a nation of 60,000,000 healthful and happy people, and coming generations will say of us then in the words of our motto, "They builded better than they knew."

ANDREW YOUNG.

The convention then went into executive session after which it adjourned until 9 o'clock in the evening.

WEDNESDAY EVENING SESSION.

The evening session was not largely attended, and was devoted to the reading of papers. John J. Weaver, of Philadelphia, read an essay on "The Inspection of Plumbing and House Drainage," followed by a paper by Joseph P. Gallagher, of St. Louis, on "The Best Method of Keeping out Back Water." A paper by J. J. Wade, of Chicago, on "The Exhibition of Plumbing Materials and Workmanship at the World's Fair" was read by J. R. Alcock, and an essay by J. D. Adamson, of St. Paul, Minn., on "The Best Means of Controlling the Water Supply of Buildings in a Cold Climate," was read by Mr. Weaver. The last paper of the session, "Traps, and What is Known of Them as at Present Used in the Plumbing Trade," by D. M. Quay, of Kansas City, Mo., was also read by Mr. Weaver. The thanks of the convention was voted to the authors, and provision was made for printing the papers.

THURSDAY MORNING SESSION.

The convention met at 9:30 o'clock. The report of the Treasurer showing receipts of $4,700.14: expenditures of $2,883.88, and a balance on hand of $1,123.88 was read and referred to the Auditing Committee.

Mr. Kennedy, of Pittsburg, presented a communication which had been received by the Secretary of the Master Plumbers' of Pittsburg and Allegheny on the apprentice question, as follows:

> At a meeting of the Twin City Association No. 4, of Journeymen Plumbers and Gas Fitters, it was decided that after the first of May no member of the association should receive less than $3 a day; also, that the association register all apprentices, and that the term of apprentices be five years, three years to be served as helping, and two years to be at the employer's disposal.

This was referred to the Apprentice Committee.

State Vice President J. R. Alcock, of Chicago, introduced the following resolution, which was adopted:

> That this national body appoint each association in the United States a day of exhibit at the World's Fair, the State Committee to commence action at once, said association in each State to be controlled by a chairman, who shall be appointed at this convention, and who shall direct the display, the State chairman to be the State vice-president.

The convention then adjourned until 2.30 o'clock in the afternoon.

THURSDAY AFTERNOON SESSION.

The election of officers was the first business, and Messrs. Horgan, Pollasheck, Tumly, Noble and Fitts were appointed tellers.

On motion of Mr. Gabay, of New York, seconded by Mr. Murphy, of Cincinnati, and Mr. Finnerty, of Boston, Robert Griffith, of Chicago, was unanimously chosen as president of the association for the ensuing year.

For vice-president Jeremiah Sheehan, of St. Louis, and Joseph A. McDonald, of New York, were nominated. A ballot gave McDonald 105, Sheehan 53, Mitchell 1 and Hussey 1, and Mr. McDonald was declared elected.

For treasurer Mortimer J. Lyons, of Brooklyn, and W. F. McCarthy, of Denver, were nominated, and the ballot gave Lyons 81 and McCarthy 70, and Mr. Lyons was declared elected.

J. R. Alcock was nominated by President Griffith and unanimously elected as secretary.

J. J. Hamblin, of Chicago, was elected financial secretary.

W. F. McCarthy, of Denver, William Mitchell, of Boston, N. D. Hussey, of Omaha, W. G. Reed, of Rochester, L. B. Cross, of Kansas City, were chosen Executive Committee.

The following State vice-presidents were then chosen:

Colorado.—M. A. Dolan, Denver.
Connecticut.—L. B. Mills, Bridgeport.
District of Columbia.—James Lockhead.
Delaware.—Alfred Gawthrop, Wilmington.
Florida.—William Clark, Jacksonville.
Illinois.—David Whiteford, Chicago.
Indiana.—J. Madden, Fort Wayne.
Iowa.—William Ellomund, Sioux City.
Kansas.—Thomas Lloyd, Kansas City.
Kentucky —Simon Shulhafer, Louisville.
Maryland.—William Drummett, Baltimore.
Michigan.—Edward Sterner, Flint.
Minnesota.—S. H. Rothwell, Duluth.
Missouri.—David M. Quay Kansas City.
Maine.—G. L. Learned, Waterville.
Massachusetts.—Daniel Shannon, Boston.
Nebraska.—James H. O'Neill, Lincoln.
New Jersey.—J. F. Blackshaw, Jersey City.
New York.—Martin Fallon, Brooklyn.
Ohio.—Richard Murphy, Cincinnati.
Pennsylvania.—B. F. Call, Pittsburg.
Rhode Island.- W. L. Whipple, Providence.
South Carolina.—R. L. Long, Charleston.
Tennessee.—T. J Mooney, Nashville.
Texas.—George W. Kite, Fort Worth.
Virginia.—W. E. Foster, Norfolk.
Vermont.--P. L. Lyons, Montpelier.
Wisconsin.—E. T. Doyn, Milwaukee.
Utah.—J. J. Farrell, Salt Lake.
Oregon.—J J. Owens, Portland.

Cincinnati was chosen as the place for holding the next national convention.

The customary resolutions of thanks were passed.

A resolution recommending that the association name a candidate for sanitary superintendent of the World's Fair was referred to the Executive Committee, after which the convention adjourned.

STEAM PIPES OF THE NEW YORK STEAM COMPANY.

THE largest pipes procurable when the work of construction on the plant of the New York Steam Company was commenced were 15 inches outside diameter. These were ordered ¼-inch thick, making the inside diameter 14½ inches. Several miles of this pipe were laid, principally for supply mains and on Broadway. At a later date pipes 16 inches outside diameter were obtained, and a length of nearly a mile of this size was put in. A small length of pipe, 13 inches outside diameter, and a larger quantity, 11 inches outside diameter, also were used for distributing mains. The thickness of the latter was 0.21 inch, and all larger sizes were uniformly ¼-inch. These larger pipes were secured in flanges by a process of rolling somewhat similar to that used to secure boiler tubes. The end of the tube, however, abutted against a turned shoulder, and the seat against which the metal was forced by the rollers was expanded towards the end of the pipe so as to make a dovetail joint. The backs of the flanges of all pipes used as steam mains are provided with a recess about ¼-inch wide and 1 inch deep around the pipe, to receive calking material in case of leakage. It was at first intended to bore this recess and insert a wrought iron calking ring. The joints, however, of all kinds proved so satisfactory that, to give additional stiffness, the recess was merely filled with rust joint material, which could be readily cut out in case of leakage.

Screwed pipe, of good quality, was adopted for steam mains less than 8 inches inside diameter. The smaller, long mains were of 6-inch pipe, but 4-inch was used in some cases for short distances. The flanges were all put on the pipe by machinery in the shop. Service pipes are generally 3 inches in diameter, though occasionally 2-inch pipe is used for small consumers.

THE attempt of the London County Council to have the special assessment, there called the "betterment," principle applied in improving the Strand has failed. The committee of the House of Commons which had the bill in charge decided that the proposed application of the principle would not be proper, but did not pass upon the principle itself.

BOXING FOR AN INDIRECT RADIATOR.

W. F. **Porter** & Co., designers and contractors for hot-water and steam heating, at Minneapolis, Minn., have adopted and used the method of boxing indirect radiators shown in the accompanying illustration, which practically explains itself.

The interior of the casing is tin-lined, the heavy black line designating the tin protection. In the bottom of the casing one or more of the boards may be arranged free to slide by easing up the matching, thus affording an additional air supply to that coming through the regular cold air duct S if desired. The duct S, as shown, is fitted with a slide placed near the opening, a section of the duct at this point being shown in the smaller engraving. The grooves in which the slide works are ⅜ inch deep. Within the radiator box, and underneath the radiator, is a "spreader," consisting simply of a partition with variously sized openings, as marked in the sketch, the sizes of the openings increasing with their distance from the junction with the cold air duct. This "spreader" tends to equalize the flow of air over the radiator in a manner readily understood.

The style of boxing shown Messrs. Porter & Co. consider the best for the northwestern climate, claiming that with galvanized iron casings the severe cold is liable to chill the cellar to an uncomfortable degree.

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

AMMONIA REFRIGERATION.

John W. Archer, Pawtucket, R. I., writes: "Would like to learn if there is a rule for calculating the heat required to convert ammonia into vapor, anhydrous, I believe it is called, used in cold storage plants and ice-making machinery, and the amount or measurement of ammonia needed for a given area to be cooled. Does the continual application of heat cause a continual increase in pressure, or is it governed by increase of heat? What would be the result if ammonia was subjected to 212 degrees boiling water? Would that cause vaporization to any extent, or does it need a higher degree of heat to be effective?"

[Bearing on this inquiry the De La Vergne Refrigerating Machine Company, of New York, to whom we submitted it, writes:

"Regarding the answering of this question we would say that the conditions under which the cooling of rooms is to be effected varies so much that it is absolutely impossible to give any rule about it. The whole question is one of practical experience, and we might even go as far as to say a question of individual experience. Of course we have general rules by which we estimate the capacity of a refrigerating machine as needed for a special purpose, but to give such a rule to anybody not experienced in these matters would be totally useless. Even experts in our business sometimes find it very difficult to establish the basis for refrigeration. It depends on climate, on insulation of the rooms, on the manner in which the rooms are to be used, on the kind of goods that are to be stored, on the number of persons that work in the rooms, and whether warm goods are brought into the rooms, what they consist of, what their temperature is when they go in, and a great many other items that it is impossible to figure on by any general rule.

Regarding your correspondent's inquiry all we are able to answer is this: The amount of heat that is necessary to convert one pound of anhydrous ammonia into vapor is about 560 thermal units, but to figure on the quantity of ammonia that it is necessary to evaporate to cool certain rooms is, as we have just now explained, a matter of individual experience and judgment. What the result would be if the ammonia was subjected to a temperature of 212 degrees we are not able to state. The table of pressures that we have at our disposal only goes up 104° Fahr., and the pressure at this temperature is 213 pounds per square inch. If heated to a temperature of 212 degrees the pressure would very likely go up to 600 or 700 pounds."

To the above we would add that according to a table of temperatures and pressures based on Regnault's observations, and which extends to 179.1 degrees, the pressure of anhydrous ammonia (which is the pure, dry gas, an aqueous solution being sometimes used for refrigerating purposes), is 623.47 pounds per square inch. At the temperature of boiling water, or 212 degrees, the pressure would, of course, be still greater since, according to the laws governing the behavior of gases, an increase of heat or temperature will always cause either an increase of volume or of pressure. As to the vaporization of anhydrous ammonia it should be stated that the gaseous state is maintained at ordinary temperatures and pressures.

As to the amount of ammonia needed to cool a given volume, the communication from the De La Vergne Refrigerating Machine Company explains, in a measure, the difficulties encountered in attempting to give a precise answer. It may be interesting, however, to follow, in connection with this, the different steps in an ammonia refrigerating process. Cooling, or expansion, coils are, of course, used. The ammonia gas is drawn from these coils by pumps at a pressure varying from 10 to 15 pounds above that of the atmosphere, and is then forced into condensers where a pressure of from 125 to 175 pounds per square inch usually exists. There liquefaction takes place, and the resulting liquefied gas is allowed to flow to a stop cock having a minute opening, which separates the compression from the expansion side of the plant.

Heat is absorbed by the expanding gas in the cooling coils, the latter being connected to the suction or low-pressure side of the apparatus from which the pumps are continually drawing the gas, thereby reducing the pressure to the above mentioned figures—10 to 15 pounds. The liquefied ammonia in again assuming a gaseous condition, owing to its expansion, reabsorbs a quantity of heat equal in amount to that originally held, and given up by it during liquefaction, the latter being termed the latent heat of evaporation. The liquefied gas, in entering the cooling coils, is suddenly relieved from a great part of the pressure and begins to boil, passing into the gaseous state at the same time. The heat necessary for this can be supplied only from the substances surrounding the cooling coils, and these are, therefore, reduced in temperature. The quantity of heat taken up by the gas is the same as that which was expelled from it during its compression and liquefaction in the condensers.

To illustrate this numerically we will refer to some figures given in a paper on a test of a refrigerating plant presented by Prof. De Volson Wood at the Cincinnati meeting of the American Society of Mechanical Engineers. In the case there taken the liquid ammonia reached the expansion coils at a temperature of 67.4° Fahr. On passing the valve on the expansion coil the pressure fell to 28.88 pounds absolute, the corresponding temperature being — 2 degrees. Hence the fall of temperature was 69.4 degrees, during which operation heat is given out by the ammonia, the amount being $69.4 \times 1.08 = 74.95$ thermal units. The factor 1.08 is the specific heat of the liquid ammonia at the temperature — 2 degrees. Passing along the coils the liquid absorbed heat until it was evaporated at the temperature — 2 degrees, after which the temperature of the vapor was increased to 35.9 degrees. The latent heat of ammonia at — 2 degrees is 565.6 thermal units. The specific heat of ammonia gas being 0.50836 the heat absorbed in raising the temperature of the vapor 37.9 degrees will be $37.9 \times 0.50836 = 19.27$ thermal units.

The heat removed from the cold room per pound of ammonia hence will be, $565.6 + 19.27 - 74.95 = 509.92$ thermal units. Taking 142 thermal units as the latent heat of fusion of ice, we have for each pound of ammonia used an ice-melting capacity of

$$\frac{509.92}{142} = 3.591 \text{ pounds.}$$

If it be desired to cool air for ventilating purposes, for example, we may proceed as follows: Suppose we supply 2,000 cubic feet of fresh air per person per hour, the air being initially at 80° Fahr. The density of this air will be .0736, and the total weight of the air supply per person per hour will be $.0736 \times 2{,}000 = 147.2$ pounds. To cool this amount, say 10 degrees from 80 to 70, we must remember that the specific heat of air is .238, and there must, accordingly, be abstracted $147.2 \times 10 \times .238 =$ about 350 heat units per hour. This means, the latent heat of ice being 142.8, that there will be melted and must be supplied $\frac{350}{142.8 + 38} =$ about 2 pounds of ice per hour for each person. For each 1,000 persons, then, the ice consumption for a decrease of temperature of the air supply equal to 10° Fahr., will be about one ton of ice per hour. The capacity of an ice machine, based on such calculation, may then be chosen.

Should our correspondent contemplate cooling of any kind, however, we would suggest that consultation with a reliable maker of refrigerating machinery would probably prove most satisfactory in the end.]

"SHOOTING" A WATER WELL.

At the pumping station at Ford, England, of the Herne Bay Water-Works Company, the process of "shooting" a well was recently successfully carried out. According to the London *Engineer* the well, although carried 576 feet below the surface, yielded little or no water. Under these circumstances the firing of several heavy charges of an explosive at intervals in the bore hole, from the bottom upwards, was tried with the view of breaking into a fissure and thus striking water. The explosive adopted was roburite, fired by electricity. The first charge consisted of 27 pounds of roburite, at the bottom of the boring; the second charge weighed 25 pounds, and was lowered to a point 50 feet above the place where the first was exploded. The second shot was so successful that it was considered unnecessary to proceed further. A large volume of water at once made its appearance at the mouth of the bore pipe, and has since continued to rise.

PUBLICATIONS RECEIVED.

Annual Report of the Board of Public Works of the City of Milwaukee, for the year ending December 31, 1889; pp. 349.

Annual Report of the City Engineer of the City of St. Paul [Minn.], for the year ending December 31, 1889.

A Popular Treatise on the Electric Railway; by H. B. Prindle; pp. 56; Boston, Mass.; E. B. Stillings & Co.; 50 cents.

TRADE PUBLICATIONS.

STEAMED FILTER WELLS.

The advantages of the steamed filter wells of the National Water Supply Company, of Cincinnati, O., are set forth at length in a recently issued catalogue. A description is given of the method of sinking these wells, and a number of testimonials are published from places where they are in use.

STEAM AND HOT WATER RADIATORS.

The Exeter Machine Works, Exeter, N. H., have issued a new illustrated catalogue, devoted to their steam and hot water radiators. Several designs are shown and particulars of trade interest are given. Illustrations are shown also of the Exeter Manifolds and the Exeter Low Pressure Damper Regulator.

THE BOYNTON HOT-WATER HEATER.

A pamphlet bearing the above title and devoted mainly to the interests of the Boynton boiler for hot-water heating, though giving also an outline of recent advances in the heating of public buildings, dwellings, churches, schools and apartment houses, has been brought out by the Boynton Furnace Company, of New York and Chicago. Illustrations and descriptions are given of the Boynton boiler, explaining its design and construction, and tables of sizes and prices are added. The pamphlet further contains interesting extracts from reports of the Hatch Experimental Station of the Massachusetts Agricultural College, headed "Steam Heat *vs.* Hot Water," and a short chapter on the hot-water system of heating.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

CONTRACTING INTELLIGENCE

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." *Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.*

Persons who make any use of the information they find in these columns we trust will not omit to mention THE ENGINEERING & BUILDING RECORD as the source

For works for which proposals are requested see also the "Proposal Columns," pages i-ii-x-64.

WATER.

For Additional Water Items see Proposal Columns.

NORMA, NEB.—A proposition to expend the sum of $3,000 on a system of water-works for this place is receiving the attention of the public officials.

BRINKLEY, ARK.—The Brinkley Water-Works, Electric Light and Power Company will sink additional artesian wells at this place to improve the water supply.

HUNTER VILLAGE, N. Y.—It is reported that a system of water-works is to be established at this place at an early date.

PHILLIPSBURG, KAN.—Reports say that the sum of $20,000 has been appropriated for the purpose of establishing a system of water-works at this place.

SILVER CITY, N. M.—There is considerable talk of establishing a system of water-works at this place.

GLENDALE, MASS.—A system of water-works is talked of for this place.

ST. LOUIS, MO.—The Board of Public Improvements, on June 20, declared the contract of O'Donnell & Brothers, for the construction of section "A," of the water-works conduit forfeited, and a new letting will be advertised.

SHELBYVILLE, KY.—An election is to be held here at an early date to decide the question of establishing a system of water-works. For particulars address L. C. Willis, as above.

MERIDEN, CONN.—Engineer Bishop, who has been investigating various sites for the purpose of procuring an additional water supply, has submitted his report to Mayor Page and the Aldermen, and it is expected that important steps in the desired direction will soon be taken.

WEST RUTLAND, VT.—Dr. J. D. Hanrahan and others are interested in the proposed organization of a stock company to provide this place with water-works. A company is to be organized with a capital of $25,000.

ELKINS, W. VA.—The Ohio Valley Improvement Company has been incorporated here by H. G. Davis, S. B. Elkins and others, with the privilege of building water-works, gas-works, bridges, etc. The capital stock is $20,000.

WASHINGTON, D. C.—A stand-pipe will be erected at the Freedmen's Hospital and Asylum. Hon. J. W. Noble will furnish particulars.

GREENVILLE, ALA.—Reports say that a Philadelphia, Pa., firm has made a proposition to establish a system of water-works at this place.

JACKSON, TENN.—Extensions will be made to the local water-works plant. Address the Mayor for information.

PARKERSBURG, W. VA.—Reports say that this city will probably put in new boilers at the pumping station. Address the Mayor for details.

STOCKBRIDGE, MASS.—It is proposed to expend the sum of $150,000 on a new system of water-works for this place.

SANDY CREEK, N. Y.—The people of this place are discussing the water-works question. Estimates made give the probable cost of a suitable system at $18,000. Engineer E. D. Smalley can furnish particulars.

BERLIN, N. Y.—The Berlin Water Company has been incorporated at this place with a cash capital of $5,000. For particulars address William F. Fay, as above.

YOAKUM, TEX.—Reports say that the officials of this place desire to have a water-works plant established by outside parties, and operated on the franchise plan.

PALMYRA, MO.—This place has decided in favor of establishing a system of water-works. Address Frank Sosey for particulars.

OLYMPIA, WASH.—The Olympia Water-Works Company has been incorporated at this place, with a capital stock of $150,000.

MACUNGIE, PA.—The taxpayers of this place are discussing the question of establishing a system of water works.

EDGERTON, O.—The water-works question is receiving the attention of the citizens and officials of this place.

PINE PLAINS, N. Y.—The question of expending the sum of $20,000 on establishing a system of water-works is being considered by the taxpayers of this place.

SHELTON, WASH.—Reports say that this place is to establish a system of water-works.

GOSHEN, IND.—The authorities of this place are considering plans for the improvement of the local water-works plant.

FREEHOLD, N. J.—The people of this place have voted to establish a water-works plant, and to own it themselves.

GRAND FORKS, DAK.—The Grand Forks Water, Light and Power Company has been incorporated at this place with a capital stock of $100,000.

LANCASTER, PA.—As a temporary relief to the citizens of the West End, who complain of a scarcity of water, it is proposed to lay a 20-inch water main, in connection with the stand-pipe, to that portion of the city. As soon as possible permanent measures will be taken. Address Mayor Clark for details.

AMERICUS, GA.—The people of this place will hold a public election July 10 to decide whether or not to issue bonds in the sum of $25,000 for the purpose of extending the local water-works system. Address the Mayor for particulars.

TRENTON, N. J.—Governor Abbett, June 20, signed Senator Pfeiffer's repealer of the act which gave Camden power to issue $1,000,000 of bonds for an improved water supply.

WELLSTON, O.—It is proposed to build water-works here.

MANCHESTER, N. H.—The Board of Commissioners of this place are considering plans for an extension of the water supply and for the building of a new reservoir.

EUSTIS, FLA.—City Clerk Arthur G. Smith writes: "The city have granted exclusive franchise to A. D. Wright and J. De V. Hazzard, of Eustis, who propose to lay about 11 miles of mains for the purpose of irrigation, principally, incidentally furnishing water for household uses and fire protection for the city of Eustis, Fla.

PROVIDENCE, R. I.—It has been ascertained that the necessary repairs to Fruit Hill Reservoir will cost $75,000. The matter is in the hands of the Committee on Highways.

SPRINGFIELD, MASS.—The City Council has finally passed the measure to issue bonds in the sum of $125,000 for the purpose of making necessary improvements to Ludlow Reservoir.

GALESBURG, ILL.—The time for opening bids for the water-works at this place has been postponed until July 8. See our Proposal Columns.

EDSON, WASH.—A system of water-works is to be established at this place by the Samish Water Supply Company.

ZANESVILLE, O.—The water-works have been authorized to issue $50,000 worth of bonds to build a stand-pipe and lay a 30-inch main over a mile in length. There will also be an additional 12-inch main 2 miles in length.

MILWAUKEE, WIS.—The following proposals for the construction of a water-works tunnel were opened by the Board of Public Works, June 20. The work is divided in six parts, as follows: 1, shore tunnel, per lineal foot, including distributing well with connections, and the gate well copings, etc., 260 feet long; 2, shore shaft, complete, per lineal foot, with coping and cover, and all connections, 153½ feet deep; 3, lake tunnel, per lineal foot, including extensions on opposite sides of each shaft, 3,157 feet long; 4, lake shaft, complete, per lineal foot, including iron cylinders with connections, 140 feet deep, 5, furnishing and putting in place the crib, complete; 6, rock excavation per cubic yard, 120 yards. The following are the names of the bidders, with the figures given for each part of the work in their respective positions: John O'Niel, Milwaukee, Wis., $33, $234, $33, $435, $28,400, $7; total, $238,820. Wm. Forristal, Milwaukee, Wis., $30, $50, $30, $225, $43,000, $10; total, $185,885. J. J. Crilley, Milwaukee, Wis., $25, $400, $25, $400, $120,000, $7; total, $323,665. The bids were considered too high and rejected. The work is advertised and new proposals will be received until June 30.

ROCHESTER, N. Y.—At a meeting of the Executive Board held June 20, the following contracts were awarded: For furnishing cast-iron water pipe in the following quantities: Donaldson Iron Company, of Emaus, Pa., for $13,435.63. Forty tons 12-inch, 168 tons 10-inch, 56 tons 8-inch, 215 tons 6-inch, 42 tons 4-inch, 25,000 pounds special castings. The contract price is $13,435.63. The contract for as many water meters as the city deems advisable to procure was awarded to the American Frost Meter Company of Boston, at the following figures: ½-inch meters, $13 each; 1-inch, $28.50; 2-inch, $72; 4-inch, $290; ¾-inch, $21.50; 1½-inch, $52; 3-inch, $145. The Board awarded the contract for pumping machinery for the Gates well to the Holly Manufacturing Company, of Lockport, N. Y., at the following figures: A No. 5 Gaskill duplex compound condensing engine, guaranteed capacity 1,500,000 gallons per 24 hours, $4,950; 5x16 boiler, $1,200; 70-foot smoke stack, $240, making a total of $6,390.

MADISON, IND.—This place is agitating the question of water-works.

GRAND FORKS, N. D.—The City Council has repealed the ordinance passed at the last session giving Ordway & Rogers, of St. Paul, exclusive franchise for thirty years for electric lighting and water-works systems.

LOS ANGELES, CAL.—The city of Los Angeles is agitating the question of owning and constructing her own water-works. The water would have to be taken out of the river about five miles above the city. The expense of the works would be about $150,000,000.

EAST CHATTANOOGA, TENN.—Regarding the project for water-works at this place B. Thompson writes: "Definite plans have not yet been formulated; will be soon.

PERTH AMBOY, N. J.—The people of this place are becoming more urgent in their demand for a new water supply. At a recent meeting of the Taxpayers' Association the entire session was devoted to a discussion of the subject, and Mr. Convery proposed the collection and publication of all facts bearing on the water supply. The president, secretary and Mr. Buel were appointed a committee to ascertain the probable cost of a supply from Millbrook, five miles distant.

GLEN ELLEN, CAL.—The construction of a system of water-works at the Home for the Feeble Minded at this place is to be commenced immediately. The site for a 200,000-gallon reservoir has been selected, at an elevation of 150 feet above the building.

STOCKTON, CAL.—The sum of $35,000 has been appropriated for the completion of the water-works system at this place.

WATER-WORKS.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Ogden, Utah; Galesburg, Ill.; Key West, Fla; Brooklyn Village, O.; Toronto, Ont.; Binghamton, N. Y.; Des Moines, Iowa; Glenville, O.; Canton, O.; Washington, D. C.; Fargo, Dak.; St. Louis, Mo.; Atlanta, Ga.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

SACO, ME.—The sum of $10,000 has been appropriated at this place for the continuation of the Woodbury brick sewer extension.

BRUNSWICK, GA.—Reports say that at a recent election the people of this place voted the sum of $300,000 for the purpose of doing additional sewerage work.

TROY, N. Y.—The Common Council has authorized the construction of numerous additional sewers. Address the Public Improvement Commission for details.

HARTFORD, CONN.—It is proposed to construct a main sewer on Pearl street, this city. The City Clerk can furnish particulars.

KNOXVILLE, TENN.—City Clerk S. B. Kennedy writes: "The city has appropriated $2,500 to pay for survey and plans for a system of sewerage. That work is now in progress, and when completed and estimates of probable cost made, the proposition to issue bonds for the construction of sewers will probably be submitted to a vote of the people."

COLUMBUS, O.—Our correspondent writes: "George E. Waring, C. E., is here to investigate the plans of a main intercepting sewer, eight miles long, and intended to convey the sewage of the city about four miles south of the same, where it is discharged into the Sciote River."

GARDNER, MASS.—McClintock & Woodfall, C. E., Boston, Mass., have been engaged as engineers in charge on construction of sewers in this place.

REVERE, MASS.—McClintock & Woodfall, C. E., Boston, are working over a system of sewers for this place. Some action is expected from this town soon.

READERS of **THE ENGINEERING AND BUILDING RECORD** interested in the Contracting News Department of that paper are respectfully requested to examine those columns every week, and advise the Editor of any item which they may find that, in their judgment, is of no value to any one other than the person mentioned.

ST. STEPHEN, N. B.—McClintock & Woodfall, C. E., Boston, are making surveys for a partial system of sewers for this place.

PASSAIC, N. J.—Passaic some time ago concluded to build a sewer, the outlet being into the Passaic River. The City of Newark objected to this on the ground that the discharge of the sewage would pollute the water which Newark used for domestic purposes. An injunction was obtained from the Chancellor restraining Passaic from going on with the work of constructing the sewer. The Chancellor dissolved the injunction, deciding that Passaic had the right to use the river as a sewer, and that this right was superior to Newark's right to use the river for a supply of water for domestic purposes. An appeal followed, and now the highest tribunal in the State sustains the Court of Chancery.

STOCKTON, CAL.—The sum of $85,000 has been voted by the taxpayers of this place for the purpose of establishing a system of main sewers.

DAVENPORT, IOWA.—Gordon H. Nott, C. E., of Chicago, Ill., has submitted his report regarding the proposed system of sewers for this city, and it is probable that he will be engaged to prepare working plans with necessary details for its construction.

Calais, Mass.—McClintock & Woodfall, C. E., Boston, are making surveys for a system of sewers for Calais.

Hoboken, N. J.—The following resolution has been passed by the Mayor and Council of this city: "Resolved, That City Surveyor Thomas H. McCann is instructed to prepare, in co operation with A. Fteley, Chief Engineer of the New York Aqueduct Commission, a general sewerage plan of the city, to be presented to this Board with their report as soon as possible."

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

Ottawa, Ill.—It is proposed to erect a new bridge over the Fox River, in this city. Address Alderman Armstrong for particulars.

Knoxville, Tenn.—The Board of Public Works has presented the city engineers report on the location of the West Fifth Avenue bridge, which will be erected at a cost of $14,626. The report was adopted.

Rye Neck, N. Y.—A new bridge will soon be constructed over the Mamaroneck River at Barry Avenue.

Toronto, Ont.—The construction of a high level bridge over the Don at King Street, at a cost of $150,000, was recommended by the engineer at a meeting of the Board of works, held June 18, upon receipt of a petition from the property owners interested and benefited by the construction of this bridge. The report was referred to the Sub-committee on the Don Improvement.

Franklin, Pa.—The following bids for four single-span iron bridges were received by Venango County Commissioners June 19:

Bidders.	36-foot span. Price per Lineal foot.	42-foot span.	64-foot span	57-foot span.
Groton Bridge Co., Groton, N. Y	$17 33	$16.88	$18.23	$18.23

* Awarded contract for all four bridges.

Elizabeth, N. J.—A committee has been appointed by the Board of Freeholders to report upon the advisability of constructing two bridges in Plainfield, one over Cedar Brook and the other on Prospect Avenue. Mr. Vanderbeek, of the Board, can furnish particulars.

Asheville, N. C.—Reports say that Richmond Pearson contemplates building an iron bridge across the French Broad River at this place.

Montreal, Can.—The following appropriations for bridge work have been recommended by the city officials: St. Catherine's Street Bridge over the C. P. R. tracks, $90,000; Ontario Street subway, $80,000; Mountain Street Bridge, $160,000; Wellington Street Tunnel, $32,000.

Fairhaven, Wash.—The following bids for the construction of a single-track iron drawbridge over Nooksack River, weight 335,000 pounds, were received by J. J. Donovan, Chief Engineer F. & S. R. R., May 13: New Jersey Steel and Iron Company, Trenton, N. J., 4$\frac{7}{10}$ cents per pound, f. o. b. Chicago, $15,745; Elmira Bridge Company, New York, 4$\frac{4}{10}$ cents per pound, f. o. b. Chicago, $14,740; Detroit Bridge and Iron Works, Detroit, Mich., 4$\frac{1}{4}$ cents per pound, f. o. b. Chicago, $14,237.50; Passaic Rolling Mill Company, New York, 4$\frac{4}{10}$ cents per pound, f. o. b. Chicago, $14,740. Contract awarded to Detroit Bridge and Iron Company, Detroit, Mich.

Stockton, Cal.—The people of this city have voted the sum of $25,000 for the construction of bridges.

Columbus, O.—The City Civil Engineer has been directed to prepare plans and estimate for the construction of a viaduct over the railroad track crossing, at High Street.

Dayton, Ore.—The contract for a steel bridge over the Yamhill River was let June 16 to Hoffman & Bates for $14,000. Tubular piers 63 feet high; length of span about 340 feet.

Minneapolis, Minn.—The County Commissioners have awarded the contract for the Cedar Avenue bridge across the Minnesota River. The contract for the stone work was let to W. D. Van Norman on the following terms: The County to pay $9.40 a yard for stone, Red Wing limestone being used; $50 a yard for granite and $22 a thousand for lumber; piling above the cut-off, 15 cents per foot; below, 30 cents per foot; oak piling, 31 cents. The contract for the superstructure was let to the Smith Iron Bridge Company.

Newark, N. J.—Reports say that the residents of this city are agitating for a new bridge across the Passaic River, from the lower end of the city to East Newark.

Pueblo, Col.—The sum of $10,000 is to be expended on an iron bridge to be erected here.

Bridges.—See our Proposal Columns for information regarding bridge construction at the following places: Columbus, O.; Mitchell, Dak; Foreman, N. Dak.; Dalton, Ga.; Mount Vernon, O.; Albany, N. Y.; Salinas City, Cal.; Pembina, N. Dak.; Ritchie, W. Va.

NEW DEPOTS.

Binghamton, N. Y.—A new depot is to be built by the D., L. & W. Railroad Company. The plans and specifications are all ready and the arrangements are nearly completed.

THE Editor of THE ENGINEERING AND BUILDING RECORD is always glad to receive items of news for the Contracting News Department. But such items are not considered news except when the prices and particulars of the award of a contract are given. The announcement that ——— has sold ——— to ——— without giving the *prices* and particulars concerns only the buyer and seller. Such notices are always excluded, except in the case where a certain firm is stated to have taken a certain contract, the execution of which would require that they should buy certain materials. Such an item would be used if deemed of more than local interest, because it would suggest to some readers the possibility of their making a sale or securing a subcontract.

STREET-WORK AND PAVING.

Concord, N. H.—McClintock & Woodfall, C. E., Boston, are to do considerable street work here.

Newark, N. J.—The street paving bill has become a law through Governor Abbett's signature, and $2,000,000 can be spent for that purpose. This year a sum of $1,000,000 will be appropriated in the tax levy for a beginning of the work.

Elizabeth, N. J.—The contract for the improvement of Westfield Avenue has been awarded to E. M. Lynch, of this city, to pave with Telford at 83 cents per yard.

Brooklyn, N. Y.—City Works Commissioner Adams has decided to repave numerous streets with granite blocks.

Stockton, Cal.—The sum of $50;000 has been voted for doing necessary work on the public streets.

North Plainfield, N. J.—The Borough Council has authorized the construction of numerous macadamized roads.

Columbus, O.—The bids for laying new pavements in the State House yard have been rejected, and the Adjutant General has been instructed to readvertise for new bids, to be opened July 14.

Rutherford, N. J.—The people of this place propose to issue bonds in a sufficient amount to undertake extensive road improvement.

GAS AND ELECTRIC-LIGHTING.

Dubuque, Iowa.—A system of tower lighting is proposed for the public streets of this place

Oregon, Ill.—The Oregon Electric Light Company will establish a plant at this place.

Brookline, Mass.—At the recent town meeting called for the consideration of public lighting by electricity, it was voted that the Selectmen be required to look into the subject, and the sum of $35,000 was appropriated for the erection of a town plant.

Elgin, Ill.—Reports say that the Elgin Watch Company will put in a complete electric lighting plant.

Seattle, Wash. — The Seattle Electric Light Company has been reorganized with a capital stock of $500,000, and will proceed to erect an additional plant. Messrs. T. H. Tyndall, James A. McWilliams and others are interested.

Keokuk, Iowa.—This place wants proposals for public lighting, either with gas or electricity.

Webb City, Mo.—The Jasper County Electric Power Company will establish a plant here.

Port Huron, Mich.—A gas plant is to be established at this place.

Austin, Tex.—The Austin Gas Light and Coal Company will add new machinery and 4,000 feet of 3-inch pipe.

Rahway, N. J.—Articles of incorporation have been filed by the Rahway Electric Light and Power Company, whose capital is $50,000. The incorporators and stockholders are John B. Simonson, of New York City, Welles P. Ayer, of Boston, Mass., and others. The company's plant will be located here, where it will compete for lighting the city with electricity.

Brandon, Man.—The Brandon Electric Light Company contemplate the following additions to its plant: 85 horse-power engine, 2 dynamos, and 1,200 lights.

Osage City, Kan.—The Councils of this city have authorized Charles Stackhouse and others to erect an electric light and power plant here.

Chatham, N. Y.—The Board of Trustees of the local electric light company has voted to increase the capacity of the plant, and will enlarge the building and add machinery.

Passaic, N. J.—The Electric Light Company will increase the facilities of its plant, and add new machinery. Two engines, 125-horse power and 100 horse-power, 80 horse-power generator and 1,300 lights, are among the contemplated additions.

Johnson City, Tenn.—Architect R. W. Hill, of Waterbury, Conn., is preparing plans for an electric light plant to be built at this place, under the direction of A. M. Young, electrical engineer, also of Waterbury. The plant includes a fire-proof brick building one story high, 97x64, with wing 17x37. A 600 horse-power engine will be put in.

Paterson, N. J.—The following proposals for public lighting have been opened here: Paterson Electric Light Company, $135.75 a light for three years, and $128.50 for five years; the Universal Electric Light Company, of New York, for $170 a light; the Edison Company, $140 for three years and $135 for five years; while the gas company's bid was $20 per lamp.

Rushville, Ill.—The electric light question is being discussed at this place.

Aberdeen, Wash.—The Aberdeen Electric Light Company has increased its capital stock to $25,000, and will expend $10,000 in extending the system.

Tampa, Fla.—The Florida Electric Company has been incorporated here, with a capital stock of $50,000. J. R. Ritter, Howard C. Levis, S. Giglio and others are interested.

Palmyra, Mo.—An electric light plant is to be established at this place.

Cartersville, Ga.—The Georgia and Tennessee Construction Company of this place has been incorporated by H. M. Smith and G. H. Aubrey. It is privileged to develop mineral and timber lands, build and operate electric light, gas and water works, factories, etc. The capital stock is $50,000.

Quincy, Ill.—Reports say that a number of Chicago capitalists have formed a joint stock company, with a capital stock of $400,000, to put up an electric light and gaslight and fuel plant in this city. The company binds itself to lighting gas, for the next five years, at $1.50 per 1,000 cubic feet, and fuel gas at $1 per 1,000 cubic feet for the same length of time After five years the price will be $1 for lighting gas and 90 cents for fuel gas. The company proposes to make corresponding reductions in electric lighting.

Camden, N. J.—The following proposals for lighting the streets for the ensuing year were opened June 23 by the Lighting Committee of the Common Council: Camden Heat and Lighting Company, electric arc lights, 40 cents per night; incandescent lights, $29 per year; Ball Electric Light Company, of New York, 200 arc lights, $100 per year each; Fort Wayne Electric Light Company, arc lights of 2,000 candle power, 30 cents per night. The foreign companies bids were all contingent that the city must grant them the right and franchise of erecting wires. The Camden Gas Light Company were awarded the contract for lighting the gas lamps at $10.75 per lamp per year. The Pennsylvania Globe and Gas Light Company were awarded the contract for furnishing oil lamps at $22 per lamp. The awards for electric street lighting were not made.

Electric Railways.—New electric railways will be established and improvements will be made to those already built, at the following places: Paducah, Ky.; Westfield, Mass.; Baltimore, Md.; Greenville, S. C.; Marion, N. C.; Little Rock, Ark.

BIDS OPENED.

Port Townsend, Ore.—The contract for the erection of the Custom House at this place has been awarded to Ritterhard & Martell, of Seattle, Wash., at $72,000.

Lowell, Mass.—The plans of the Middlesex Machine Company, of this city, for warming and ventilating the new City Hall at Dover, N. H., have been accepted. The estimated cost of the work is $10,000.

GOVERNMENT WORK.

Washington, D. C.—The following proposals for a new boiler house, etc.; also four horizontal steam boilers, etc., for the Winder Building, U. S. Treasury Department, were opened by the Supervising Architect of the Treasury Department, June 24. The first figures given are for the boiler house, and the last ones for labor, etc., to fix complete, boilers. Bidders, all Washington, D. C.: Bright & Humphreys, $5,973, $7,837; Howarth & Yates, $6,979, $7,019; John Lyon, $5,380, $6,094.75; W. E. Spen & Co., $5,838, $4,581.53; Peter Hepburn, $6,060; James L. Parsons, $7,550, $5,969; Pettit & Dupps, $6,495-35, $7,815; William Rothwell, $5,200, $8,600.

NEW CORPORATIONS.

Holyoke, Mass.—The Holyoke Hydrant and Iron Company has been incorporated here. Capital, $40,000. President, C. E. Torrance; Secretary, C. F. Smith.

INDUSTRIAL.

Jackson, Tenn.—A convention is to be held at this place at an early day to consider the feasibility of cutting a canal to connect the Tennessee and Mississippi Rivers, *via* Jackson.

New York City.—The Third Avenue Street Railway Company has been granted a franchise to operate its line by cable power instead of horses, which are now in use. Specifications have been prepared for the work necessary to make the change, and bids will be wanted at an early date. The company's headquarters are at Third Avenue and Sixty-fifth Street this city.

Niagara Falls, N. Y.—See our Proposal Columns for information regarding the construction of an 8,000-foot tunnel by the Cataract Construction Company of this place.

Pelhamville, N. Y.—The streets are being staked out in a 176-acre tract of land to be known as Pelham Heights, adjoining the N. Y., N. H. and H. R. R., at this station. Grading operations will be begun as soon as the profiles and estimates are made. The owners intend to macadamize the roadways, put in sewers, water and gas, and start building operations as soon as possible. For further information address the engineers in charge, John F. Fairchild, Mt. Vernon, N. Y., or F. Carles Merry, 83 Fulton Street, New York City.

PROPOSALS.

(Continued from page x.)

NOTICE TO CONTRACTORS.

OFFICE OF SUPERINTENDENT OF PUBLIC Works, Albany, June 26, 1890. Sealed proposals will be received by the Superintendent of Public Works until TUESDAY, July 8, 1890, at twelve o'clock noon of that day, for building a **WROUGHT-IRON BRIDGE** over the Erie Canal at FULTONVILLE, N. Y. The substructure and superstructure will be bid for and let separately. Plans and specifications may be seen for five days prior to the date of letting, at the office of the Superintendent of Public Works at Albany. All proposals must be accompanied by sight drafts on some good banking institution of the City of New York or Albany, payable to the Superintendent of Public Works for the following amounts: For substructure of bridge, $400; for superstructure of bridge, $500. Proposals must be indorsed "Proposal for Bridge ———." The right is reserved to reject any or all bids.

EDWARD HANNAN,
5 Sup't of Public Works

TUNNEL, St. Louis, Mo.—Proposals are wanted until September 1, for the construction of about 3,000 yards of tunnel. Address McCormick & O'Meara, 904 Olive Street, as above.

PAVING, Chattanooga, Tenn.—Proposals are wanted until July 10, for paving about 6 miles of streets. Address L. S. Walker, Chairman Board of Public Works, as above.

SEWERS, Marion, O.—Proposals are wanted until July 18, for constructing about 17,300 feet of 18-inch outfall sewer. Address H. S. Jones, City Engineer, as above.

PIER, New York City.—Proposals are wanted until July 9, for building a new wooden pier, with appurtenances, including sewer boxes and a dumping board, at the foot of East One Hundred and Tenth Street, Harlem River. Address the Department of Docks, Pier A, North River, as above.

GRANITE STONES, New York City.—Proposals are wanted until July 2, for furnishing a quantity of granite stones for bulkead on river wall. Address the Department of Docks, Pier A, North River, as above.

BRIDGE, Ritchie, W. Va.—Proposals are wanted until July 12, for the construction of a steel road bridge over Hughes River. Address the County Clerk of Ritch e County, as above.

SEWERS, La Salle, Ill.—Proposals are wanted until July 1, for the construction of about 15,000 feet of sewers. Address Mayor F. W. Matthiessen, as above.

CEMENT, Washington, D. C.—Proposals are wanted until July 10, for furnishing a quantity of cement. Address J. W. Douglass, Commissioner, as above.

HYDRANTS, Washington, D. C.—Proposals are wanted until une 30, for furnishing 75 fire hydrants and 50 street hydrants. Address J. W. Douglass, Commissioner, as above.

SEWERS Canton, O.—Proposals are wanted until July 5, for the construction of certain sewers. Address H. G. Schaub, City Clerk, as above.

SEWERS, Key West, Fla.—Proposals are wanted until September 1, for the construction of an underground system of sewers, also for paving and laying water mains. Address William L. Lavey, City Clerk, as above.

PAVING, Glenville, O.—Proposals are wanted until July 9, for paving certain streets. Address Charles B. Cook, Village Clerk, as above.

DIKE, Philadelphia, Pa.—Proposals are wanted until July 7, for the construction of a p le and stone dike at Bulkhead Bar. Address C. A. Raymond, Major of Engineers, U. S. A., as above.

BUILDING, South Macon, Ga.—Proposals are wanted until July 5, for the erection of a public school building. Address R. W. Cubbedge, No. 467 Second Street, us above.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22.
NUMBER 5.
PUBLISHED EVERY SATURDAY.
277 PEARL ST., NEW YORK.

NEW YORK, JULY 5, 1890.
LONDON, JULY 19, 1890.

SINGLE COPIES, TEN CENTS.
Subscription, $4.00 per year in advance, post paid. IN AMERICA
SINGLE COPIES SIXPENCE.
Subscription, 20s. per annum in advance, post paid. IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.

20*s*. in GREAT BRITAIN. Other Foreign Countries $5.

Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & CO., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $5; China, Japan, Sandwich Islands, Mexico and Cuba, $5; South America, $5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

THE NEW YORK CHAMBER OF COMMERCE AND THE MISSISSIPPI FLOODS.

THE recent widespread and most disastrous floods on the Mississippi River have been made the subject of a memorial addressed to the Chamber of Commerce of New York by a number of prominent citizens of that place, setting forth the great loss and suffering in the district immediately affected and the injury caused thereby to interests in all parts of the country. The memorial goes on to show the importance of completing the Mississippi levee system at the earliest possible date and by the general government, which alone can and should be expected to undertake a work of such magnitude and far-reaching benefit, and concludes by requesting the Chamber to take suitable action in furtherance of these objects.

In compliance with this request the Chamber adopted resolutions to the effect that the continued overflows of the Mississippi were a national disaster, that the President be requested to bring the matter to the attention of Congress, and that that body be urged to adopt such measures and make such appropriations as might be necessary to prevent such overflows in future, that concerted action by similar bodies in other cities be invited and that a committee be appointed to personally lay the matter before the President and Congress.

The committee appointed in pursuance of this resolution has visited Washington, and as a result of their appeal the Senate has added to the House bill for the improvement of Rivers and Harbors the sum of $3,500,000 for the prosecution of the work on the Mississippi levees, and it is hoped that the House will concur in this action.

As we have more than once had occasion to comment on the short-sighted policy pursued by some of the New York dailies in opposing without discrimination appropriations for river and harbor improvements in other parts of the country, it is refreshing to note such action as the above initiated by leading citizens of New York, and promptly seconded by its most influential commercial organization. We have no doubt that it will bear good fruit, not merely in securing the desired appropriations but in promoting a better feeling between different parts of the country.

ENGINEERING CONVENTIONS OUTSIDE LARGE CITIES.

THE success of the annual convention of the American Society of Civil Engineers, which met at Cresson Springs, Pa., from June 26 to 30, a report of which will be found elsewhere in this issue, thoroughly demonstrated the wisdom of the policy of the society in selecting a summer resort hotel as a place of meeting rather than a large city. All the visitors and their lady friends, of which there were a goodly number, were housed under one roof and thus kept together, acquaintanceship and social intercourse, so pleasant and essential a feature of such occasions, being greatly facilitated.

It was found that when cities were selected as a place of meeting the programme necessarily included numerous trips and visits to industrial establishments. This, besides fatiguing the visitors, seriously interfered with the discussion of papers. Moreover, it frequently happened that the local committee felt called upon to secure large subscriptions to defray entertaining expenses. This has resulted in extravagant entertainments and a feeling of obligation by the visitors, distasteful under the circumstances.

This feature was entirely absent at Cresson, as it has been from several of the recent conventions of the American Society of Civil Engineers. We notice the Railway Master Mechanics' Association have just held their convention at Fort Monroe, and we anticipate the policy of avoiding large cities as places for holding engineering conventions will be more generally adopted.

HEIGHT OF FACTORY CHIMNEYS.

AN item, now going the rounds, gives particulars of a new factory chimney in Germany which will rise to a height of considerably more than 400 feet. This, as well as several other remarkably tall chimneys frequently mentioned of late, calls to mind the fact that a large number of chimneys now in existence are of much greater height than is necessary for their purpose if the latter be simply to produce draught for boiler plants. Where chimneys are designed for carrying off noxious vapors from chemical works, as in the cases of several of the widely noticed stacks at Glasgow and one or two other cities of Scotland, there is some method in providing for unusual height, since the aim there is to insure as complete as possible a diffusion of the gases or vapors, and prevent their mingling with the air of the lower strata. With boiler plants chimneys, however, unusual height is rarely based upon a good reason.

The prevailing notion that the greater the height the greater in direct proportion the draught producing power of the chimney, is a natural error on the part of many, and has been responsible for much unnecessary outlay in chimney construction. As a matter of fact the draught-producing capacities of chimneys, having flues of the same size, are in proportion to the square roots of their heights, so that if one were to have double the power, if we may so call it, of the other, it would have to be four times as high. Attention has been directed more than once to the circumstance that beauty of design, from an architectural point of view, has had much to do with the unnecessarily great heights so frequently encountered, a much-favored rule being to make the height of the chimney equal to about 25 times the diameter of the flue. A little consideration will show that strict adherence to this ratio would bring about some rather peculiar results, as chimneys for small plants would turn out to be much lower, and those for large plants much higher, than is necessary.

The area of cross-section of chimney flues should in all cases be made to depend upon the combined areas of the boiler flues, and this, with a chimney height of about 100 feet, shown by long experience to be a very satisfactory figure, will in most cases furnish ample draught to burn any of the commonly used fuels. Applying the 25 to 1 ratio to two plants of, say two and ten boilers, respectively, all of the same size, and proportioning the flue areas of the chimneys in the way just indicated, will afford a striking illustration of the shortcomings of the rule. One hundred and fifty feet represent what has on good authority been given as the maximum height of chimney necessary in any case for producing the requisite draught, always providing, however, that the flue area has been properly proportioned. Proprietors of steam plants boasting of chimneys which much exceed this height may indulge in some profitable reflections as to the money needlessly spent in erecting such structures.

WORCESTER'S NEW SEWERAGE SYSTEM.

THE new sewerage system at Worcester, Mass., involving chemical precipitation, was put in operation last week, and experiments are being made to determine what precipitants are best. Lime and alumina have been used, both separately and together, but, because of the varying chemical nature of the sewage itself, the results with either or both are not the same from day to day. The intention is to determine what precipitant is best upon the whole by repeated trials.

SCHOLARSHIPS IN TECHNICAL SCHOOLS.

AT the recent twenty-third annual meeting of the American Railway Master Mechanics' Association, at Old Point Comfort, Va., the following resolution was unanimously adopted:

> *Resolved*, By the American Railway Master Mechanics' Association in convention assembled, that a committee of three members, consisting of J. N. Lauder, John N. Barr and Angus Sinclair, be and are hereby appointed, empowered and directed to confer with the trustees or other proper officers of the Massachusetts School of Technology of Boston, the Cornell University of Ithaca, N. Y., and the Stevens Institute of Technology, and arrange and report a plan at our next annual meeting for the investment of the principal and interest of the Boston Fund of this association in one or more scholarships in one or more of these institutions, and submit the same for approval of the association. The benefits of said scholarships to be for such time as may be directed by the association, as a prize to the sons of members who shall exhibit the most valuable attainments and skill in the development of locomotive mechanics.
>
> And be it further *Resolved*, That notice is hereby given that a vote will be taken at our twenty-fourth annual meeting to so appropriate said fund.

A previous report had shown the total amount of the fund to be at present about $6,678.

SHOOTING WELLS.

BEARING on the subject of shooting wells, George F. Chace recently remarked before the New England Water Works Association that the effect of the explosion about one time in three is to increase the water, but sometimes the supply is diminished. With respect to this H. G. Holden said:

"I have blasted several wells, and all of them but one resulted in giving more water; I never knew of a case of its being less. I blasted one on the Hudson River, a well about 1,000 feet deep, for a paper mill, where they wanted to get a large supply of pure water for making note paper. The supply was very small indeed. I put in three charges of nitro-glycerine, 25 pounds to a charge, and it was successful, as I think they have since had all the water they needed. This depends a good deal however upon whether there are any water-bearing veins anywhere in the vicinity. If there are, a heavy explosive will sometimes open the veins so as to get a great deal more water. But I don't understand how the effect would be to close anything up so as not to get as much, unless the well caved in. It might do that if it was in very soft material but, ordinarily, it makes a large chamber wherever the explosive lies."

THE AMERICAN BOILER MAKERS' ASSOCIATION.

THE American Boiler Makers' Association held its second annual meeting at New York City this week. The sessions extended over three days, with about 75 members in attendance.

The objects of the association, which was formed at Pittsburg in April, 1889, are given as follows:

To establish such standard for materials and workmanship as will insure uniform excellence of construction of all American boilers, and thus secure safety to the lives and property of all communities where boilers are used, and to procure the passage of laws making the manufacture, sale, or use of inferior materials criminal offenses.

To concert such measures and take such action as shall be for the interest and advantage of its members especially.

To procure and furnish to its members statistics of the trade, domestic and foreign, and

To take such action as shall from time to time be deemed advisable regarding the regulation of prices and production.

PASSAGE OF SPORES THROUGH CLOTH USED FOR AIR FILTERS.

IN an article on the above subject in the *Zeitschrift für Hygiene*, abstracted in Excerpts of Proceedings of the British Institution of Civil Engineers, Dr. Karl Moeller points out that air filters are of two kinds. For "germ-proof filters" he employs an ante-filter and ten layers of a specially thick, closely woven, and very much roughened material; for "dust-proof filters" only one thickness of a much less closely-woven fabric is used. Filters of the latter kind, though capable of excluding very large proportions of germs, are obviously not germ-proof. By Dr. Moeller's arrangement of the filter in the form of a series of pockets, the cloth, moreover, is used in a direction very oblique to the air current, forming an angle with it of from three degrees to five degrees, whereas in some earlier tests the cloth was at right angles to the air current. By reference to enlarged sections of the fabric, the vast difference in the degree of permeability due to this change in the direction of the movement of germs is explained. Dr. Moeller asserts that a woolly surface is one capable of entangling large numbers of germs, and that in some earlier tests the obvious precaution of sterilizing the cloth before the commencement of the experiments was neglected. A vast number of germs were thus regarded, no doubt, as having passed through the cloth, which, as a matter of fact, had been simply blown off its surface by the air current.

SEWAGE DISPOSAL AN EVANGELIZING AGENT.

A correspondent sends us the following humorous item which, it is alleged, came near appearing in a Liverpool paper. According to the story a reporter had to attend a meeting at a Wesleyan Chapel for the conversion of the Hebrews to Christianity, after which he reported the addresses given by the late General H. Y. D. Scott to the Polytechnic Society on the conversion of sewage into lime and cement. In the printer's hands the folios got mixed up, and the report read:

"The Chairman, after the meeting had been opened with prayer, explained that the conversion of the Jews was one of the greatest works that could engage the attention of our sanitary authorities. Filtration was the most perfect method that could be adopted for purification, but a filter had its limits. There was a popular notion that the sewage contained a vast amount of wealth, but the sludge must be taken out of it for purposes of irrigation, as it otherwise choked the pores of the land, and they were a wandering race spread over the whole face of the habitable globe. They were denied the inimitable blessings of Christianity, which might be counted by thousands of tons per annum allowed to run to waste, when by a judicious admixture of lime and clay, the benighted Hebrews who sat in darkness might easily be converted into lime and cement for building purposes, and if thus deodorized, after being first dried and burned in a kiln, this ancient race would once more take its proud position among the nations of the world."

"Subscriptions were earnestly solicited for the purpose, though he (the speaker) disclaimed any idea of making a profit out of the process, and, in conclusion, he urged increased efforts in the good work, showing that, thus deodorized by a very novel process of evangelization in large tanks constructed for the purpose, the grateful Hebrews might flow over the land without injury to vegetation, while the expense of conversion, which was progressing as rapidly as the best friends of Christianity could wish, would be more than repaid by the sale of the phosphate of lime and valuable cement for building purposes."

A GRAND JURY in New York City has made a presentment in regard to street pipes and subways which tells the familiar story of the evil in vigorous language, and suggests, as remedies, that no more permits for laying steam and gas pipes be given for streets already overcrowded, and that ultimately a non-political commission be created to consider "a new system by which the benefits of steam, gas, water, electricity and sewage can be had more safely, and with less official obstructions."

NOTES.

ABOUT 40 members of the Architectural League of New York went to Tuxedo Park on June 25, as guests of Bruce Price.

THE Secretary of the Permanent State Road Association of Illinois reports that there were nearly 200 iron bridges erected and nearly 2,000 miles of gravel or macadam roads made in Illinois last year, and that the figures will be larger for this year.

"SCHISEOPHONE" is the name of an electrical instrument recently tested at the Ermont Works on the Northern Railway of France, its object being to indicate the exact spot where interior flaws exist in iron or steel rails. It is stated that the result of fracturing rails to prove the indications of the instrument showed it to be reliable.

THE Federal Senate has passed the bill incorporating the North River Bridge Company, before passed by the House. This represents what is known as the "Lindenthal" project, from the name of the engineer who designed the bridge between New York and New Jersey. Another bill is being urged upon Congress, authorizing the New York and New Jersey Bridge Companies, chartered in New York and New Jersey, to build the projected structure across the Hudson. This represents the "Greene" scheme, and is reported to be pushed with the agreement that more than one bridge will be necessary.

A FAILURE in the water supply of Nashville, Tenn., June 27, compelled the sudden drawing of fires under boilers and the consequence was that all electric cars were stopped without warning wherever they happened to be and that factories had to shut down. A fire in the old pumping station had disabled a part of the machinery and a leak in the suction pipe of one of the pumps still running compelled stopping for repairs and so reduced the water supply as to cause the inconvenience mentioned. The water-works of both Nashville and Cincinnati are now in very unsatisfactory condition, furnishing a scant supply at best and under such circumstances that a single accident to machinery might easily prove a grave disaster to the city.

OBITUARY.

JOHN PAGE, Chief Engineer of the Canadian Government railways and canals, died suddenly at Ottawa, Ont., Wednesday. He was 74 years old. He came from Scotland to the United States in 1838 and worked in the construction of the Erie Canal, after which he went to Canada. He directed the construction of the St. Lawrence Canal system, and prepared the plans for the canal now being built at Sault Ste. Marie, Ont.

EDWARD FRY, Chief Mechanical Engineer of Brooklyn, N. Y., died recently. He had been in charge of the pumping engines of the Brooklyn Water-works 12 years.

CHARLES R. ARMSTRONG, aged 23 years, was drowned in the Delaware River, Tuesday, while bathing. He was a draughtsman at the Edgemoor Bridge Works, and lived in Auburn, N. Y.

FREDERICK F. WELD, City Engineer of Waterbury, Conn., died of typhoid fever June 28 at the age of 40 years. He had been City Engineer of Waterbury since 1884 and had served as a member of the Board of Health. His illness is reported to have been due to the use of impure milk, and one of his daughters is critically sick, apparently from the same cause.

PERSONAL.

HENRY C. MEYER, Editor and Proprietor of THE ENGINEERING AND BUILDING RECORD, sails on the steamer Umbria to-day for his annual European vacation trip. He will return about the middle of August.

GEORGE PARKER has been appointed Engineer and Superintendent of the Water-Works at Galveston, Tex.

CHARLES PAINE, Past-President Am. Soc. C. E., has formed a partnership with two of his sons, with the name of Charles Paine & Sons, and the firm has opened an office in New York City as consulting engineers.

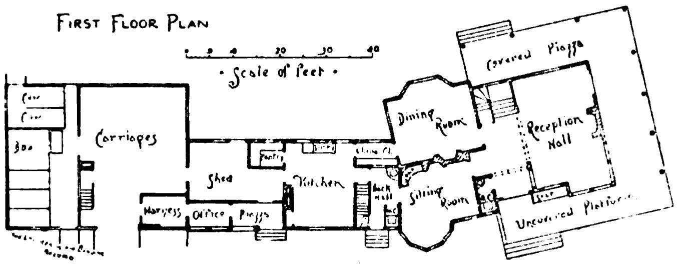
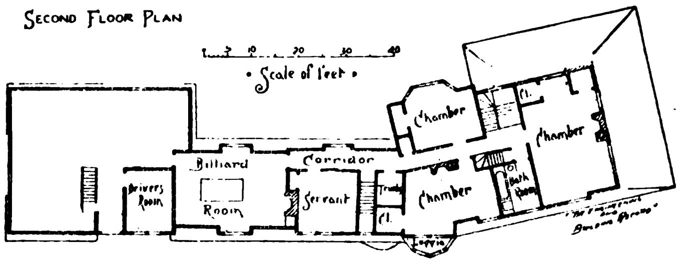
ANNUAL REPORTS.

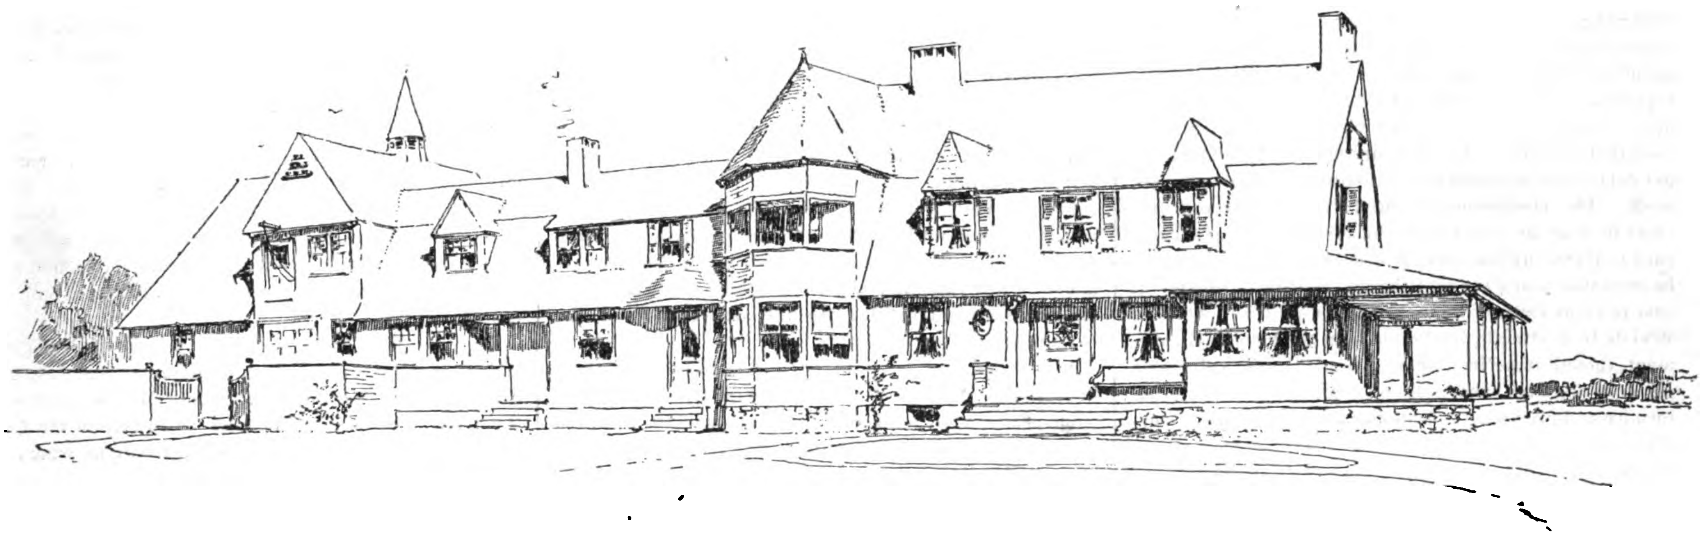
Third Annual Report of the Board of Public Works of Duluth, Minn., for the year ending February 28, 1890; William B. Fuller, City Engineer.

In their last annual report the Board of Public Works of Duluth note that the city has in a number of cases been sued for damages caused by the encroachment upon private property of the cuts and fills necessary in grading the streets. They also call attention to the inequitable method of levying assessments, especially for sewers, by which one man has been made to pay $429 for the same improvement that another man gets for $61. Reference is also made to the reports of Rudolph Hering and Andrew Rosewater on a proposed system of sewerage and sewage disposal, and of A. P. Boller on a proposed drawbridge over the ship canal at Minnesota Point, which will be noted separately.

Street improvements to the amount of $279,137 were contracted for and nearly completed. Six storm sewers were completed, at a cost of $34,083, or $5,500 less than the engineer's estimate, and eight sanitary sewers, at a cost of $57,888.







JOHN K. MARTIN'S HOUSE, BRIDGETON, ME.—STEVENS & COBB, ARCHITECTS.

The following are some of the contract prices: Excavation, per cubic yard, earth, highest, 40c., lowest, 20c., average, 28c.; rock, $4.50, 50c., and $1.66; borrow, per cubic yard, 45c., 1c., 31c.; gravel and rolling, per cubic yard, $1, 50c., 78c.; loam, per cubic yard, 55c, 40c., 48c.; paving, per square yard, cedar block, $1.19, 93c., $1.07; pine block, average, $1.32; Telford macadam, average, 90c.; rough stone for gutters, $1.28, 50c., 83c.; rough stone in Portland cement, $1.60, $1.25, $1.43; B. M. timber in place, per M., $20, $15, $17.46; curbing, per lineal foot 18-inch granite, average, $1.40; 18-inch Berea sandstone, 93c., 83c., 88c.; 20-inch Berea sandstone, average, 70c.; excavation in sewer, per cubic yard earth, 80c., 35c., 49c.; rock, $4.50, 50c., $2.61; sewer pipe laid in concrete, per lineal feet, 24-inch, $2.50, $2, $2.30; 21-inch, $2.30, $2, $2.18; 20-inch, $1.95, $1.60; $1.82; 18-inch, $1.90, $1.30, $1.57; 15-inch, $1.35, $1.05, $1.23; 12-inch, $1.25, $1.10, $1.18; sewer pipe laid in sand, per lineal foot, 18-inch, $1.20, 80c., 97c.; 15-inch, 75c., 55c., 63c.; 12-inch, 75c., 50c., 58c.; 10-inch, 60c., 16c., 44c.; 9-inch, 62c., 30c., 38c.; 8-inch, 40c., 25c., 29c.; 6-inch, 25c., 10c, 18c.; brick sewer, with granite block bottom, per lineal foot, 39-inch, average, $4; Portland concrete sewer, per lineal foot, 36-inch, average, $5; 28 inch, $3.50, $3.40, $3.45; 26-inch, average, $4; sewer brick, per M., $20, $17, $17.75; masonry, per cubic yard cut stone, $25, $15, $21.75; mortar rubble, $4.50, 80c., $3.08; piled rock slope, per cubic yard, average, $1.25; peen hammered work, per square foot, 40c., 25c., 33c., catch-basins, each, $55, $30, $42.95; manholes, each, $95, $38, $51.76; automatic flush tanks, each, $125, $85, $100.31; lampholes, each, average, $18; inlets, ⅛ bends, each, $3, 90c., $1.40; cast iron, per pound, 4c., 3c, 3½c.; removing and relaying sidewalks, per lineal foot, 10c., 5c., 7⅙c. The contract price for plank sidewalk was about four cents per square foot, and for one piece of sandstone sidewalk, 12 feet wide, and including curb and filling, it was $7.92 per lineal foot.

The city has been lighted since May 4, 1889, by from 121 to 183 arc lamps of 2,000 candle-power each, at a total cost of $15,793. The price per night for the first 100 lamps was 35 cents and 33⅓ cents for each additional lamp. The total expenditure for public buildings was $60,698, and plans for a jail and police station, to cost about $25,000, are under consideration.

Water is supplied by the Duluth Gas and Water Company, who, during the last year, constructed and put in operation a 4,000,000-gallon reservoir 280 feet above the lake. Over 10½ miles of water mains were laid during the year, making 28 miles in all. Of hydrants 56 were set, making 199 in use, and of services 239 were put in, making 1,059 in all

The water is taken from Lake Superior and the works have a capacity of 5,000,000 gallons per day. The total pumpage was 683,117,002 gallons or 1,871,553 per day, giving 124 gallons a day to each of an estimated population of 15,000 supplied.

The company is required to extend its gas and water mains whenever an annual income of 50 cents per lineal foot of mains is guaranteed.

Three block plans are given showing methods of apportioning special assessments for street improvements.

The cost, for engineering, of investigation and report on petitions for improvements was 0.29 per cent. of the estimated cost of the proposed improvements, aggregating $814,596. The cost of engineering on $522,011 of work done was 2.01 per cent. and the cost of inspection was 1.03 per cent.

Brick and stone gutters have been used on new graveled avenues at about half the cost of the wooden gutters heretofore used and are considered much superior. Their annual cost of maintenance will, however, be greater, except when the wooden gutters have to be renewed.

Nearly 50,000 square yards of paving were laid. On a street where there is 1,200 feet on a grade of 12 to 13 per cent. a pavement of rectangular pine blocks was adopted. They were 4 inches wide and set on end in rows 1 inch apart on a 2-inch plank foundation, the space between the blocks being filled with tar. As an experiment, 150 feet of this street on a 13 per cent. grade was paved with cedar blocks without tar, and some on a 10 per cent. grade with cedar blocks with tar; no blocks exceeding 6 inches in diameter. Over 15 miles of sidewalk were laid altogether.

A two horse street sweeper was purchased from the Abbott Downing Company, of Concord, N. H., which has given good satisfaction. Of sewers, 3.7 miles of sanitary, and 2.9 miles of storm water have been constructed, making the totals in use 15.9 and 6 miles respectively. One 36-inch storm-water sewer drops 22 feet on a reverse vertical curve, at the same time changing its horizontal direction 90 degrees in a length of 87 feet. The grades of each end are 2½ per cent., and at the steepest point 37 per cent. It is made of a concrete of crushed granite and best Portland cement.

Borings to a depth of 118 feet were made at the site of the proposed bridge over the ship canal by the following method:

"Two-inch wrought-iron pipe was sunk by means of a hydraulic jack, gravel, shale or similar material being in advance of the pipe, by a drill, and the sediment and other loose material removed by flushing with water forced to the bottom of the well through a ½-inch pipe placed inside the larger one. In soft material the water jet was used simultaneously with the hydraulic jack."

The intention of the University of Pennsylvania to establish a school of architecture is announced.

ANNUAL CONVENTION OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS.

(From our Staff Correspondent.)

CRESSON, PA., July 1.

A SPECIAL train on the Pennsylvania Railroad which left New York at 10 o'clock A. M. Wednesday, June 25, and arrived here about 7 P. M., brought 109 members and guests of the American Society of Civil Engineers, 40 of whom were ladies, to the convention. The majority started from New York, but smaller parties joined at Trenton, Philadelphia, Harrisburg and Altoona, where the only stops were made. Dinner was served in the dining car, and social enjoyment and the beautiful and picturesque scenery afforded universal entertainment throughout the trip. Various engineering structures of interest that were finished or under construction along the line of the road were noted during the ride, among them some skew masonry arches.

THURSDAY MORNING SESSION.

The first session of the convention was held Thursday morning, Vice-President William Metcalf presiding. J. Foster Crowell presented a paper on "The Designing and Erection of the Oakley Arch," a structure notable for its obliquity of 42° 32′ (which, the author said was about the most unsafe angle to which a semicircular arch could be applied,) for an original device for attaining security, and for its excellent mechanical execution and workmanship. The arch carried one double-track railroad, and embankment, over another, its abutments rested on pile foundations, and its barrel was made of brick, the rest of the masonry of stone. During construction traffic was maintained by the alternate trestle system. Great trouble was experienced from the faulty formation of the underlying rock. A detailed description was given of the methods of design, which were considered valuable on account of their simplicity, conciseness, dependence upon computations instead of intricate drawings, and their reliability and interchecking character. Full-sized templates and not drawings were used by the mechanics. The exact angles of the ring stones were cut at the bridge site, to a level gauge. The diagrams, progress and construction of the arch were fully described and illustrated, and the laying out of the different stones and lines of the structure minutely explained. The author noted the comparison of alternate designs and estimates, all of which were less economical than that adopted. The masonry used cost about $10.50 per cubic yard, against $10 for adjacent first class straight work. The conclusions deduced were, that in ordinary cases of average dimensions the average cost per cubic yard of the entire masonry of a skew construction would be increased 3 to 4 per cent. by the helicoidal treatment, that in many cases of light skews it is not worth while to deviate from straight joints, and that the helicoidal treatment, though imperfect, affords security to the vulnerable parts of the arch and is to be commended for its uniformity and preciseness of application as against the complicated variations of the theoretically perfect equilibrated arch. Also, that it secures the full measure of strength of material and high economy, and should be adopted because more nearly approximating to all the requirements where symmetry and strength are desirable and unsightly features are to be excluded.

After the presentation of this paper, another by A. S. C. Wuertelle, M. Am. Soc. C. E., on "The Stability of Loaded Masonry Arches," was read by title and presented in printed form for discussion with the Oakley Arch Mr. Wuertelle's paper contained analytical and graphical investigations and mathematical deductions on the strains in the middle third of the arch, locating the line of pressure, finding the depth of the keystone, unequally loaded halves of arches, and the conditions of stability. A supplement to this paper contained an analytical investigation of and mathematical formulæ for uniformly varying stress in foundations for reservoir walls and abutments to arches and for the greatest intensity and deviation from center of pressure in foundations.

Discussion.—Desmond FitzGerald: "Would it have been advantageous to have made the acute wing nearer right angles to the arch?"

Mr Crowell: "No, on account of the position of the creek on one side. Its direction was considered in proportioning and no loss resulted."

D. J. Whittemore: "Was an estimate made of the comparative cost of an iron girder structure?"

Mr. Crowell: "Yes, showing little difference. The design was determined by the necessity of providing for future raising of the grade embankment."

Mr. Whittemore said that in a cold climate the action of the frost usually separated the brick from the ring stones, his remark being based on his experience in the Northwest.

H. M. Wilson: "I recently saw in India a peculiar skew arch, which was a combination of road bridge and masonry regulator, at the head of a Ganges canal that was at a peculiar angle to the river so as to have caused silting with a different angle of arch. The structure was double decked, with gates 15 feet high and an overhead roadway. The engineers made a large preliminary brick model of it, 60 feet high."

G. Bouscaren: "Why is 40° 30′ the most unfavorable angle for this arch, as stated by Mr. Crowell?"

Mr. Crowell replied that on account of the position of the point of eccentricity the culmination of insecurity comes between 45 and 40 degrees, and illustrated his remarks by a blackboard diagram.

Col. Latham Anderson: "What quality of stone was used?"

Mr. Crowell: "Ordinary good limestone at an average cost, for all masonry, of $10 per yard. Oolitic limestone in large blocks was used for the ring stones at an extra cost."

Question: "How much camber did you give?"

Mr. Crowell: "None, and there was no settlement."

Mr. Anderson: "What was the strength of the oolitic stone, and how did it spawl at the angles? What is the compressive strength of Indiana flat rock, Salem quarries? I have found it to crush under small loads."

Mr. Crowell: "There were no comprehensive tests made. Layer stone would probably be stronger in its natural bed, but a stone was required to resist equally in both directions, and to have large dimensions, both of which qualities were secured in the oolitic stone used. I had misgivings as to the durability of any stone under such acute angles, but these pressures were not abnormal."

Prof. O. H. Landreth: "In recent tests of Indiana oolitic stone I got about 5,000 pounds to the square inch in a set of 15 cubes, two of which were accidentally set with the bed vertical, and gave very different fractures which extended across the cube at an angle of 30 degrees with the bed of the machine."

Francis Collingwood said that he would always avoid filling the joints close to the face until the mortar is well set. Point it up afterwards, and this often prevents serious spawling.

Mr. Crowell: "It is very important not to point at first. In a certain brick arch the inner course was carefully filled and pointed, and the other seven courses were laid with less care, and when the center was struck the inner course was crushed along the skew backs and had to be replaced."

J. B. Francis: "Two reasons for spawling have long been known; the edges are more perfectly cut, and the stone is absolutely weaker at the edge as shown by experiments. The ancients fitted stones carefully and then shaved off the edges."

Charles Paine: "It would be well to record many instances of skew arches. There is a handsome cut stone arch of 50 feet span at Silver Creek on the Lake Shore Railroad."

A voice: "There is a skew arch under Seventh Street, St. Paul."

Mr. Crowell: "Will these gentlemen send notes of these instances for addenda to this paper?"

Alphonse Fteley: "The Pennsylvania Railroad is constructing many skew arches. I noticed two of them yesterday that were each composed of many straight arch sections or ribs. Can any one tell why this method is used? I should think the excess of area of face work would make it much more costly. By recent experiments I have found that, under the same head, the flow of water is 40 per cent. less with natural ragged sides than with smooth cement sides of a channel 10 feet wide. A mere wash of Portland cement applied to the brickwork with a brush increases the flow 2 or 3 per cent.; therefore this construction must greatly retard the flow."

Question: "Were these Pennsylvania Railroad bridges over highways or waterways?"

Answer: "Both."

Mr. Crowell: "There are other reasons against this Pennsylvania Railroad arch construction. It decreases the effective diameter, the area of the foundations must be increased, and the use of these parallel ribs precludes bonds except for short distances in the middle of the arch. Adjacent rings can be bonded together but in different relative positions, therefore the railroad above will overload one rib and underload another."

Mr. Francis explained the construction of small skew arches built like straight ones except that the end stones were cut special, and illustrated with a blackboard diagram.

A voice: "At the Johnstown flood a bridge constructed with independent rings, as described by Mr. Fteley, had two of the rings carried away without injury to the remaining ones."

P. F. Brendlinger: "I find the parapet a very important factor of strength of the face wall. I have built many ordinary false skew arches [illustrating by blackboard diagrams] that have stood several years and served satisfactorily. Mr. Crowell's method of arch construction is nice when you have plenty of time and engineers; mine is very simple and easy for large work and can be built by any mason with one tin template."

Mr. Crowell: "A prime object of my paper is to show that the helicoidal system is the simplest. The stones are alike except the faces and all are easily made by the same pair of parallel rules. We built this arch with a contractor who was not skilled and ordinary stone cutters and there were only two stones miscut out of 86. The only four tables required for data I made in a few evenings so that ordinary draughtsmen made the record drawings from them."

Mr. Brendlinger: "What was the total amount of masonry in the Oakley arch?"

Mr. Crowell: "Three thousand five hundred and ninety-three yards, on which there was an extra allowance of about 50 cents per yard."

Mr. Brendlinger: "With small abutments the contractors would certainly increase the bids for this construction."

Mr. Crowell: "This is an average arch with small abutments. In extreme skews the material should certainly be placed to the best advantage. I wish to show that when you build a skew arch it is very easy to build it right."

The Secretary read a paper by F. W. Watkins, M. Am. Soc. C. E., on "A Method of Taking Cross Sections in Deep Rock Cuts by Triangulation." The work described was in a railroad cut half a mile long and attaining a maximum depth of 100 feet. The slope of the material could not be determined until the bottom was reached, and the excavation occupied two years, and was recross-sectioned for final estimate after completion. Many places could only be reached by ropes or ladders, so triangulation by vertical and horizontal angles was made with a transit having a vertical arch and horizontal level tube. The method of working was illustrated and discussed.

Desmond FitzGerald informally presented a diagram and observations concerning evaporation, the result of data got at the Boston Water-Works last summer when the temperature was 80 degrees at the top of the reservoir, and constant at 42 degrees at the bottom, which was constantly filled with organic matter that floated steadily through until turned over in the fall. The water was found at the same temperature at the same level for any depth and was sometimes clear, beginning to cloud at different times at different depths.

THURSDAY AFTERNOON SESSION.

Lincoln Moss, C. E., presented a paper on "Comparative Tests of an Electric Motor and a Steam Locomotive on the Manhattan Elevated Railway, New York." The paper gave a detailed description of the conditions of the experiments conducted by the author with a 4-car train and the methods and apparatus employed, described the electric plant and analyzed the conditions, data and results. It was illustrated by plates and diagrams and developed the estimate that the cost of direct electric propulsion would be four times that of steam locomotion.

Discussion.—A. M. Wellington thought that the results of the paper might be interesting as to the general relative efficiency of electric and steam motors, and that other existing motors might make a better showing.

Mr. Moss: "The great trouble is in handling the current at starting. The loss is great at starting up a grade and the efficiency increases with accumulating velocity. Great losses are caused by external resistances."

A. E. Hunt: "I agree with the paper. We can develop 80 per cent. of efficiency in generating a current, but not 80 per cent from the current back to the motor."

Mr. Wellington: "I know of a plant whose motor does not stop at all, and waste is avoided by utilizing different velocities inverse to the power."

Oberlin Smith: "This shows why New York elevated roads don't run electric motors. They try to run electric locomotives when they should, instead, apply the power directly to the car cables, proportioned to the varying load. If we can utilize 50 per cent. of the force it will be doing well."

A member: "This paper does not represent the best modern results of electrical engines. I have found in a general way, in experimental investigation of street motors, that there is a first loss of 15 per cent. from steam engine to dynamo, 15 per cent. from dynamo to motor, and about 10 per cent. in the line."

J. B. Francis: "Sir W. Thompson stated before the Canadian Parliament that 10.000 horse-power could be delivered from Niagara Falls to Montreal by a ⅝-inch conductor."

Mr. Moss: "There have been two other systems experimented with on the New York Elevated Roads: one where the motor never stopped, and was differentially connected to the wheels; the other had the motive power applied directly to the wheels. Neither system was ever pushed vigorously or amounted to anything. This is simply a record of actual tests of a system that attained results compelling the company to recognize it in competition with locomotives."

H. M. Wilson presented an abstract of a paper on "Irrigation in India." The following are some of the headings enlarged and explained:

Immigration is a necessity to the financial success of any irrigation enterprise in the United States. India was overpeopled previous to introduction of advanced and extensive irrigation enterprises; but since their construction easily supports a much larger population. Administration of irrigation projects in India. Organization there of ministerial and of engineering branches of government. Extent and powers of control over water and land. Seasons; rainfall; crops; evaporation and stream discharges, and methods of determination and nomenclature used. Results, good and bad, of irrigation; alkalinity; water logging; drainage; fevers. Irrigation works—their kinds. Well or lift irrigation. Inundation canals. Protective or famine works. Productive and perennial works. Perennial works good investments. Protective works have not often been financial successes. Why storage (protective) works may pay in United States. Water rates higher in United States. Volumes of discharge of large rivers. Topography in Northern India. Location of canal heads. Location of diversion weirs. Open weirs or "barrages." Weir foundations. Wells or brick caissons. Temporary boulder weirs. Masonry weirs. Under sluices; sluice gates; regulators; escapes. Source of supply. Alignment of canals; duty of water; width of channel and cross-section. Velocity of water in canals; slope of canal bed. Distribution of water; irrigation of fields. Storage reservoirs; location; catchment basins; flood discharges. High dams of masonry; waste weirs; water cushions, scouring or under sluices.

Discussion.—Question: "What is the maximum velocity in canals?"

Answer: "It differs greatly; in light sand from 1¾ to 2½ feet per second. In soils a little more stable from 2½ to 4 feet, and is unlimited in rock and gravel."

J. B. Francis (referring to the great size of the canals): "The flow of the Mississippi in recent floods was 1,300,000 cubic feet per second."

Desmond FitzGerald. "I understand that the water cushion formed the only protection for the bottom against the overflow at weirs; I should like to see it before abandoning the belief and practice of a lifetime."

Mr. Wilson: "At one weir that had a flow of 90,000 cubic feet per second there was, just below, an island formed of 10 feet of gravel by hard pan and kunkar. Wishing to remove it they cut channels through the gravel, but it still remains, having withstood the current for two years without much erosion."

Mr. Francis: "At Niagara the falls have made a water cushion about equal to their own height, and further erosion is prevented by it."

A paper by Arthur Pou on "The Cheapest Railroad in the World," was read by the secretary. It described the conditions and construction of a 19-mile railroad from Dublin to Wrightsville, Ga., the most of which was built at a cost of about $1,100 per mile. It was imperative to construct the road in the absolutely cheapest manner. The engineer only devoted part of his time to it, convict labor at $1 a day was employed, adjacent growing timber was used, and good second-hand rails were bought very advantageously.

A paper by R. H. Thurston on "The Permanent Effects of Strain in Metals; on Their Self-Registration and Mutual Interactions," was read by the secretary. The author summarized previous papers in which he had arrived at the conclusion that if a metal be subjected to a stress of any given kind, or in any stated "sense," sufficient to produce permanent strain and set, then its ultimate resistance to that, or to any other kind of stress, will be sensibly increased, and in all directions, whatever the line of action of the deforming stress. Four series of experiments were made, in illustration in each of which the material employed was subjected to strain in either tension, compression, torsion, or by transverse loading; and the application of another straining force was then made to reveal the permanent effect of the first, and the altered elastic limit and ultimate resistance. The results, visible to the unaided eye, were believed to demonstrate the principle, and from another experiment on brass it was concluded to be possible to detect with it a behavior similar to that of iron. The paper was accompanied by tables of data and photographs and descriptions of the tests.

Discussion.—Prof. J. B. Johnson: "It is well known that any cold working increases the strength of iron. I have drawn 50,000 pound iron to 40,000 or 50,000 pounds and thereby increased its ultimate strength to 70,000 pounds. This increase depends on the time. If a 50,000-pound specimen be broken, one of the pieces may the next day rise to 58,000 pounds, and by waiting two weeks, to 70,000 pounds. Wire drawing is another and a familar illustration. I think this indicates a mistake in the universal objection that engineers have to using iron in structures after it has been strained beyond its elastic limit, and probably improved instead of injured thereby."

F. W. Skinner: "Professor Johnson's remarks seem to imply the desirability of subjecting structural iron to strains beyond its elastic limit before putting it in the structure. Many very serious objections to this immediately arise. We are all familiar with the fact, well established by experiments, that iron which will endure uninjured almost an infinite number of strains each considerably below its elastic limit, will be quickly destroyed by greater strains, especially shocks such as bridges are subjected to, within its original ultimate strength, but equal to, or perhaps somewhat less than, its elastic limit. Machines do not now exist capable of imposing such strains on most full sized structural members, and if it were attempted to strain them after they were assembled and connected in the finished structure, the results, from the very definition of elastic limit as the point where permanent set begins, would cause such distortion and variation of principal dimensions as to entirely change the conditions and destroy the symmetry of the structure. Furthermore, straining any member or element beyond its elastic limit would inevitably aggravate defects, develop and increase flaws, and make dangerous trifling imperfections that would never have become important under working strains."

Professor Johnson: "I don't mean to advocate increased working strains of structures, but that engineers should not hesitate to use iron that has once been strained beyond its elastic limit. For example, a chain strained to a 10 per cent. elongation is improved and has its welds tested. The iron is improved for loads within, but not above, the elastic limit. The great point is what influence the stress in one direction has upon the strength in another direction."

Francis Collingwood: "These stresses impair the elongation. This is not detrimental in wire, but such treatment would take the life out of bridge members and any engineer would hesitate to be responsible for it. Such members, when readjusted to bearing, would take unequal proportions of the working stresses and soon be destroyed."

D. J. Whittemore: "I once tested rods from an old highly strained bridge and found them improved."

G. H. Thomson: "I tested some old Howe Truss Bridge rods that had been used up to 35,000 pounds and they showed an ultimate strength of 70,000 pounds; but so did some unused rods from the same bridge."

William Metcalf: "The statement that the ultimate strength in every direction will be increased by strains above the elastic limit is dangerous to young engineers. Rolling produces its greatest distortion lengthwise by wave motion in the iron in front of the rolls; this gives great increase of strength in the direction of rolling and great loss in the direction at right angles to it. I once found by careful measurements that the dimensions of an iron bar were actually increased by cold rolling, thus showing a separation of particles. Elastic ductility can be secured by hot but not by cold rolling, which is a necessity, not an advantage. Hot rolling would be better if practicable. Professor Thurston's experiments clearly show local distortions; these must be injurious. If you suspect cold rolled material of being brittle, break it transversely and if it shows a black core with a bright ring outside be very careful of it; it is more dangerous than big crystals and shows crushing in the center or some other injury."

THURSDAY EVENING SESSION.—THE PRESIDENT'S ADDRESS.

At the session Thursday evening President W. P. Shinn delivered the annual address, which he said was, according to a constitutional mandate, a review of the year's engineering progress.

Mr. Shinn first mentioned the completion of the Forth Bridge, notable for containing the longest spans in the world; two of 1,710 feet clear, each with 150 feet clear headway beneath them, and tubular bottom chord members 15 inches in diameter. The rivet holes at the connection of one span met within ½-inch, and were brought together by hydraulic jacks. At the other span they were 1 inch apart and, failing to be closed by hydraulic pressure of 170 tons, were brought to place by the expansion of the chords by burning waste in them.

The spans were subjected to 1,800 ton test loads and deflected in accordance with computations, and deflected less than one inch under registered wind pressure of 37 pounds per square foot. The bridge contained 59,500 tons of steel and cost $15,500,000.

The St. Louis Merchants Bridge has a total length of 2,420 feet, including three 525-foot spans, and has been completed under the supervision of E. L. Corthell and G. S. Morrison, members of this society. The Kentucky River Bridge was completed in August, 1889, and is remarkable for its magnitude and rapid construction. It has a total length of 1,658 feet, including a 551-foot cantilever span supported on steel towers 135 feet high, and it was ready for passage of trains six months after the foundations were commenced. The Thames River Bridge in Connecticut was completed last October under the supervision of A. P. Boller, M. Am. Soc. C. E., and is remarkable for its 503-foot draw span, the longest in the world. The Coteau Bridge over the St. Lawrence is 6,035 feet long. Its foundation caissons were taken into position suspended between two floats. The trusses were erected at the required level on false work in six feet of water. The false work was then lifted upon floats on scows which were towed into position and sunk so as to deposit the trusses in final position on the bridge seats.

Of bridges under construction Mr. Shinn mentioned the new Louisville and Jeffersonville bridge, 8,505 feet long, with two spans of 431 feet, and two of 550 feet each, and one of 553 feet, surpassing all previous lengths of truss spans. The Ohio River bridge at Brunot's Island, under the supervision of Past-President M. J. Becker, is to be erected by C. L. Strobel, M. Am. Soc. C. E. The false work will be at right angles to the bridge, and, after the trusses are assembled upon it, will be transferred to pontoons and floated into position. The Mississippi bridge at Memphis will have one span of 791 feet, two of 621 feet each, and nearly a mile of 150 foot spans, and its cost is estimated at $3,000,000. The Tower bridge at London, England, will have its 200 foot middle span divided in the center and hinged at the piers, each end opening upwards to leave a clear opening between towers of 135 feet headway below the upper connecting trusses.

Among proposed bridges Mr. Shinn spoke of the North River bridge with a 3,200 foot span, the construction of which has been authorized by a bill providing for its commencement within three years, and completion within ten years thereafter, with a capacity for ten railroad tracks. The Mississippi bridge above New Orleans is designed by E. L. Corthell, M. Am. Soc. C. E., to have three discontinuous spans of 886 feet each, and to cost $3,000,000. A suspension bridge, 4,440 feet long, to unite Philadelphia and Camden, and accommodate railway, carriage and pedestrian travel, is proposed. The most pretentious project is that of the English Channel bridge, 24½ miles long, with 118 spans and two abutments, and spans of from 500 to nearly 1,000 feet in length. The masonry piers would be in water of 180 feet maximum depth, and carry steel towers 140 feet high, giving a headway of 177 feet. The total weight is estimated at 771,265 tons, and the total cost at $172,000,000.

In regard to bridge floors Mr. Shinn said that a train became derailed and bunched the ties, destroyed one span of the bridge and two passenger cars, killed 13 persons and severely wounded 29, besides causing a money loss of $200,000 at the St. George Bridge, where the rails were spiked to 8 by 12-inch cross timbers laid 8 inches apart on the bridge trusses without other guard rail than a timber at the ends of the cross ties. A similar accident occurred at the Flat Creek Bridge, where there were no guard rails. Both of these disasters might probably have been averted if proper guard rails and tie systems had been used. It is plain that true economy calls for solid iron floors with continuous ballast where stone arches are not used.

Speaking of railroads the President said that the estimated mileage in the United States at the end of 1889 was 161,382 miles with not less than 1,100,000 freight cars. It is to be regretted that, on the average, these freight cars stand still nine days for every day they are in motion. With a proper system of demurrage charges their average movement could readily be increased 50 per cent. Satisfactory improvement is evident in railroad management. Compound locomotives are receiving fair trial in this country. It is in safety appliances that the greatest progress has been made during the last year. Steam heating from the locomotive for passenger trains is being introduced extensively.

Compressed gas is superseding kerosene lamps for car lighting. Great advance has been made in power brakes for freight trains. It appears safe to say that within the present decade all freight cars will be equipped with automatic couplers. The subject of safety signals is one of growing importance. In the year ending June 30, 1889, there were 5,823 persons killed and 26,309 injured by railroad accidents in this country; their number might probably be reduced one-half by the adoption of the safety appliances above mentioned. One of the most important points to which the speaker would call the attention of railway managers is keeping trains on time. The speed and number of trains are matters of convenience, but to put a passenger exactly when and where you advertise to put him is a matter of contract and rests on a solemn obligation. Accidents are something excusable, but the schedule should be made practicable and be rigidly executed.

It was Mr. Shinn's conviction that the regularity and promptness of trains on many of our leading railway lines is not as satisfactory to-day as it was 20 years ago. A $60,000 appropriation towards the survey for the Two Americas Railway, projected from the United States to Chili and the Argentine Republic, has been recommended by the President and the construction of the road is likely to be commenced. The construction of the Chignecto Ship Railway from the Bay of Fundy to the Gulf of St. Lawrence will demonstrate the correctness of Past Vice-President Capt. J. B. Eads' Tehuantepec Ship Railway project. The construction of the Chignecto road is well advanced. It will be 17½ miles long, able to carry 1,000-ton vessels, will have two straight tracks 18 feet apart, and is expected to be finished next year.

As to ship canals Mr. Shinn said that The American Nicaragua Canal appears to be making substantial progress. A. C. Menocall, M. Am. Soc. C. E., is its chief engineer. Among the constructions of last year the Eiffel Tower is remarkable as being, probably, the highest structure recorded by history.

In no other branch of the profession have so great strides been made as in electrical engineering. The first electric railway was built in 1886, and in May, 1890, there were 240 electric street railways in operation and under construction. At the close of 1889 there were in New York State alone 92 electric light companies, one of which had 301 stations, with a total capacity of 554,350 16 candle-power lights. One of the most remarkable advances in the use of electricity is for welding. In one test the metal seemed to have been refined and made more homogeneous.

The present use of water power is but a fraction of that easily available in many sections of the country. A company has been formed to utilize the power of Niagara River by taking water in a canal from above the falls and discharging it through vertical shafts into a tunnel opening into the Niagara below the falls, utilizing the water at a pressure as high as 100 pounds per square inch.

Providing for the sewage of large cities is an engineering branch of growing importance. There are no more important questions than those of water supply and sewage. One of the greatest undertakings of modern times is the drainage of the valley of the City of Mexico with and area of 1,657 square miles at an average altitude of 7,412 feet above sea level. A canal 30 miles long, and tunnel 8 miles long, are proposed, to have a capacity of flow of 61.7 cubic feet per second at a velocity of 7.54 feet. This work was commenced in 1889, and is to be finished in 1891.

Special attention has been lately given to the improvement of our common roads, than which no worse can be found in any civilized country. Several State Governors have given attention to this subject in their messages. Prof. J. W. Jenks claims that in Illinois a full load can be carried on the State roads only three months in the year, two thirds of a load only three months, and half a load during six months. He claims that if the State had a good system of roads the farmers would be benefited $116,000,000 in the value of their farms, and would save annually $15,300,000 in hauling. An estimate of T. H. Johnson, member of a committee of the Engineers' Society of Western Pennsylvania, was to the effect that the loss to that State from bad roads amounts to $6,000,000 per annum, and that the present annual road tax of $4,000,000 is utterly wasted. No better example of the effect of good roads is to be found than in Union County, N. J., where the population of Elizabeth, Westfield, and Plainfield, would not have been attracted without good macadamized roads. Steps in the right direction have been taken by the University of Pennsylvania in offering prizes of $100, $200, and $400, for papers on road-making and maintenance, and by the Case School of Applied Sciences in Cleveland, offering free instruction on road-making in the form of three lectures.

One of the most remarkable improvements in the driving of shafts is that of the Poetsch freezing process, applied in quicksand. It consists of sinking iron pipes around the shaft and circulating through them a solution of chloride of calcium at a temperature of about — 17° Fahr. The natural heat of the ground is thus absorbed and the earth around the pipes is frozen into a solid impervious wall. The process is controlled in this country by a company, at the head of which is General W. Sooy Smith, M. Am. Soc. C. E. Its first work was at Iron Mountain, Mich., where it sunk a shaft 15½ by 16½ feet by 100 feet deep. A shaft has been sunk in Belgium by this process that was 190 feet deep to the quicksand and was carried 62 feet further through it.

Great advances are being made in metallurgy. Within ten years the output of a blast furnace has been more than trebled and the production of pig iron has increased 230 per cent. in 11 years. It is now possible to manufacture spiral welded tube of almost any required size and strength from rectangular strips of metal of moderate width. Improvements in the manufacture of aluminum have increased its range of application in the manufactures.

The lesson of the failure of the South Fork Dam is undoubtedly that from a too contracted spillway, and, although the rainfall which caused it was, as with the failure of the Walnut Grove Dam in Arizona, unprecedented, it shows that provision must be made for a flow of water greater than any recorded.

The engineering profession is the oldest known to history, antedating law, medicine and priesthood. Roman aqueducts, with an aggregate capacity of 28,000,000 cubic feet of water per day, are recorded 50 years before Christ. One of them was 63 miles long, including 6½ miles of arches, some of them over 100 feet high. The aqueducts supplying ancient Carthage are said to have been 70 miles long, and to have contained one arcade of 1,000 arches, some of them 100 feet high. Ancient Peruvian aqueducts are said to have exceeded all others of ancient or modern times in length and capacity, some of them bringing irrigation water several hundred miles. From recent Egyptian explorations it is stated that 5,000 years before Christ a dam was constructed that turned the whole river Nile into a location several miles distant from its former bed.

The term "engineer" is misleading in this country, where it is applied alike to the man who designs and who operates an engine, and the degree of Civil Engineer, for which the qualifications requisite for membership in this society should be demanded, is often improperly bestowed. The curriculum of engineering schools should embrace some study of law and accounts, ignorance of which often causes trouble and expense.

One of the notable events of the past year was the European visit of American engineers, who met most courteous and enthusiastic receptions in Great Britain, France and Germany, their dinner in the London Guildhall being an especially marked courtesy, never but once extended to any non-municipal visitors. Members of this society are invited to co-operate in the entertainment of a party of members of European societies that will visit this country next October.

It has long been my opinion, said Mr. Shinn, that expert professional witnesses should be called by the court and not employed to present facts and opinions in support of one side of the case only.

Care and accuracy are very important in all of an engineer's acts and statements. He cannot afford to be careless, his every estimate should be based on known data. Great odium has been brought upon the profession because its estimates have been generally too low. The actual cost of the original Croton Aqueduct was, however, less than 1 per cent. in excess of the estimate by the late J. B. Jervis, M. Am. Soc. C. E. The statement of the civil engineer should impart absolute verity, and, with his opinion, be always based on the best possible ascertainment of facts.

Most engineers have some unique experiences. These, though brief, or embracing only part of a subject, should be reported to this society whose life blood is in its papers and discussions. Our growing society shall thus be made to expand in influence and value, embracing all the members of our noble profession on this continent, a few from the older hemisphere, and become, in fact, The American Society of Civil Engineers.

The remainder of this session was occupied by a description by Robert B. Stanton, M. Am. Soc. C. E., of a five months' boat expedition through the Colorado Canon, of which he made a transit survey, with levels and stadia measurements, topographical notes and 900 photographs for the location through the canon of a low grade railroad. Mr. Stanton described his equipment and methods, the experiences and hardships of the expedition, and the results obtained. The formation of the canons, with brilliant coloring and magnificent scenery, was illustrated by 150 stereoptic pictures.

Friday morning the members and guests of the convention, by the courtesy of the Pennsylvania Railroad, took a special train to Johnstown, Pa., stopping near the site of the South Fork Dam, and at other points in the Conemaugh Valley, and visiting the works of the Cambria Iron Company. At the iron works they were received by Alexander Hamilton, General Superintendent, George Hamilton, Assistant Superintendent, C. S. Price, Metallurgical Superintendent, Joseph Morgan, Jr., Chief Engineer, and other officials of the company, and made a brief inspection of some principal features of the plant.

FRIDAY AFTERNOON SESSION.

Prof. Charles B. Brush read a paper at the session Friday afternoon on "One Way of Obtaining Brine," in which he described the reservoirs, wells, plant and methods of operating the salt works of the Tully Pipe Line Company at Syracuse, N. Y., where double tubes are sunk from the surface of the ground 1,200 feet or more to the salt beds. Fresh water being let into the top of the interior tube becomes nearly saturated with salt and is withdrawn in the form of brine through the outer tube. Thus the deposit is gradually dissolved and a great basin will eventually be formed reaching from well to well. In reply to questions Professor Brush explained that the pipes had ordinary lining that suffered somewhat from the effects of the salt and was liable to be broken by high velocities.

Henry T. Eddy, C. E., Ph. D., presented a paper on "A New Graphical Solution of the Problem, What Position a Train of Concentrated Loads Must Have in Order to Cause the Greatest Stress in any Given Part of a Bridge Truss or Girder." The object of this paper was to introduce a new graphical method for determining what position a moving train of wheel weights must have to produce the greatest stress in any given part of the bridge truss or girder over which the train is passing. The method proposed depends principally upon the construction and use of a class of polygons or curves, named reaction polygons. One of these is the line of shears. One valuable proposition respecting the load line has, however, been in constant use here since 1875, by C. L. Strobel, M. Am. Soc. C. E., and his successors in the office of the Cincinnati Southern Railway, who learned it in 1871 as a student of Professor Mohr. Reaction polygons are readily constructed graphically, and their properties are such as to give with ease the train positions for maximum stresses as well as to decide which of several maxima is the greatest. The proof of these constructions was given in algebraic form. Part I treated the simple girder and single intersection truss resting upon end supports. It contained a full explanation of the properties and methods of construction of reaction polygons and the investigation of all problems of maximum stresses in girders and single intersection trusses by their aid. Part II treated cantilevers with two supports and double intersection trusses with end supports. It showed how the same simple graphical methods suffice to resolve also all important questions of maximum stress, under concentrated loads, for bridges of these more complicated forms.

Discussion.—W. H. Burr: "How did you treat the analytical indeterminate question of a double intersection truss?"

Professor Eddy: "On the ordinary assumption that stresses starting in one system remain there, that chord strains are summations of both systems and that strains do not pass over. Pin loads were avoided by considering wheel loads directly."

W. H. Burr presented a paper on and illustrations of the three spans of the Ohio River bridge, briefly describing its construction and erection, stating that it contained the greatest and heaviest single non-continuous trusses ever made, supporting double railways, roadways, and sidewalks. He explained the details, none of which were special except floor beam and lateral connections. The most of the top chord and post rivet holes were made by multiple drills. Rivets were tested by cold hammering, and the steel plates by hammering out of shape and other severe treatment, with such satisfactory results as to give good confidence in the steel. The weight of the three main spans was 10,000,000 pounds; total weight, 20,360,000 pounds; total length, one mile. The Phœnix Bridge Company designed, built and erected it. The false work and two-thirds of the iron for one span was pushed 1 foot down stream without injury by the drift of one freshet. Another freshet swept out and completely wrecked the false work, traveler, and 700,000 pounds of steel for the 550 foot span. This accident was caused by the freshet piling up drift almost solid to the bottom of the river, below which a scum undermined the false work which would otherwise have endured as it stood the maximum height of water for some hours. The false work was immediately replaced and protected by two 600 foot double lines of piles, 5-foot centers, sheathed with 5-inch scantling and backed every 40 feet by groups of six piles. The lines were built obliquely from both ends of the false work forming a V that protected the new false work and span through several freshets. The substructure was not unusual, comprising both pile and pneumatic foundations, the latter made by Gen. William Sooy Smith. The maximum pile load was 81,000 pounds. The maximum load on the pneumatic foundations was 13,000 pounds per square foot.

The paper was briefly discussed by Frank C. Osborne, Prof. J. B. Johnson, C. L. Strobel, and the author.

The secretary read a paper by J. L. FitzGerald on "The Comparison of Water Supply Systems from a Financial Point of View." From tabulated data of water-works plant, cost, duty, expenses, revenue, etc., for 90 United States cities, the author concludes that "if any conclusions can be drawn, they may be summarized as follows, supposing in every case that the three systems of supply are open to choice: Whatever the size of the town, a gravity system would be most efficient whenever these conditions were all fulfilled; the supply of unquestioned present and future purity; the quantity sufficient for the needs of the next 20 years without great additional outlay; and the original cost such that 8 per cent. thereof will not be greater than 60 per cent. of the total operating expense, including interest and sinking fund.

"A direct pumping system will be the most economical when the town is of such a size that its daily consumption will be more than one-half million gallons; when the supply is good and abundant, but situated at a low level; and when there are no great differences of elevation in the distribution system. If there are highly elevated portions, these, when of small comparative area, or consumption are best supplied with a reservoir system, having an independent force main. When the consumption is less than one-half million gallons, direct pumping with a reservoir stand-pipe of at least 20 hours capacity, situated in the distribution system, will give the most economical results.

"When a town is so unfortunate that its supply is insufficient during certain portions of the year, or when that supply is sufficient for ordinary needs, but affords no margin for fire protection, a reservoir of large capacity will then be necessary. Works of the latter kind can only be regarded as temporary in character, the inevitable growth of the city forcing soon radical changes and possibly reconstruction.

"Although the writer is aware that no hard and-fast rules can be formulated for a choice of a system, and that a hundred local circumstances will determine the final selection, yet he believes that a few general principles like the above will afford some aid to the solution of doubtful cases."

Discussion.—Desmond Fitz Gerald: "Boston's 35,000,000-gallon supply should be classed under the gravity system. We have for several years observed storage action on a large scale, and find that it greatly improves water of a certain degree of impurity. Even good water, though not improved, may be rendered more stable, and its color benefited by storing. Storage is greatly influenced by its conditions."

J. B. Francis: 'I have known at Lowell 8-inch pipes designed for 150 pounds pressure that had been 60 years in service and were working without signs of failure at 200 pounds pressure."

F. L. Fuller: "I think that many pipe systems stand more than 20 years, and question the statement made in the paper that many companies sell water below the cost of production."

C. B. Brush: "As the author says, water-works reports are usually unsatisfactory, and this paper has been compiled from such ones. Here there is no distinction between high and low service works. There are great differences between lengths of force pipes, etc., so that the data is inadequate to draw conclusions from. The inference from the paper is that direct pumping is generally desirable; such is not my conclusion, and I protest against the statements going out without protest from this society. My experience is directly opposed to the conclusions of the writer, which I would not willingly accept without much better data."

H. M. Wilson: "Spokane, Wash., is an instance of a town without extra fire pumps. There the engine broke down just before the 4th of July, the engineer went away, fire broke out, and the town was destroyed."

Prof. J. B. Johnson: "I protest against any deductions from a table of averages where all the items are given equal weight. Here the conditions are so different that there is no comparison. A little village counts just as much as New York. Engineers should weigh facts and give them a proper relative significance. I submit that this is an absolutely vicious basis of argument."

T. H. McCann: "I notice many defects in the statement about Hoboken. If the others are not more accurate I doubt the conclusions."

A member: "I think these tables are valuable for independent use and as giving useful data of many towns."

Mr. Metcalf: "In Pittsburg we had much trouble from the pumps being clogged by mud and drift in freshets of the Allegheny River. To remedy it I had an intake well 12 feet deep dredged, cribbed and covered. We got clear water, but soon great complaint was made of lime in the water that filled up the boilers, etc., and finally it became so serious that the water was analyzed and found to be very heavily charged with saline matter. This water was evidently from a separate source just beneath the sweet Allegheny and contained three times the matter that the river did even in flood times. So we had to destroy the crib, etc., at a considerable expense."

Friday evening over 170 of the members of the convention and their guests, including ladies, attended the banquet, where the toasts and responses pleasantly alternated with the courses.

Saturday morning the majority of the members and their guests visited Bell's Gap, a special train being furnished by the Pennsylvania Railroad Company.

SATURDAY AFTERNOON SESSION.

The regular business meeting of the society was held Saturday afternoon. The Committee on the Compressive Strength of Cements and the Compression of Mortars and Settlement of Masonry reported progress, and that they were awaiting an opportunity to use a large testing machine. The report was accepted and the committee continued.

The Committee on Uniform Methods of Testing Materials used in Metallic Structures reported progress. The report was accepted and the committee continued.

The Committee on Standard Rail Sections did not present a report.

A member of the Committee on Purity of Water Supply presented a minority report, which was received and referred to the Board of Direction for action.

The Committee on Uniform Standard Time reported progress and the preparation of a memorial to Congress to pass an act to legalize this system of time. The report was accepted and the committee continued.

A communication was received from V. G. Bogue, Chief Engineer Union Pacific Railroad, stating that an engineers' room had been furnished in a hospital in Washington. It contained two beds, and $3,000 was required to endow it. The society was invited to furnish $1,500 or $2,000 of the amount, the rest of which would be raised in the West. The communication was referred to the Board of Direction.

The Committee on the Revision of the Constitution and By-Laws submitted its second progress report. It had held three meetings and been mainly occupied in considering the formation of branch societies and affiliation with existing local societies. Sixty-two communications have been received upon the subject, and a circular embodying five different plans has been sent to representatives of 27 local societies, from ten of which responses have been received. The committee has offered every possible opportunity for the expression of the views of local societies on affiliation, and had vainly hoped for personal discussion with them upon the plans suggested. "Your committee is impressed with the idea that obstacles arising in the details would make it extremely difficult to definitely conclude an affiliation plan; they are unable to report in time for action by the convention upon the general subject committed to their charge and therefore submit this report of progress and ask to be continued." The report was accepted and the committee continued.

A communication from the Western Society of Engineers asked that this society appoint a committee of its members to meet in Chicago next October, committees from other engineering societies to consider the holding of an International Engineering Congress in Chicago during the World's Columbian Exposition of 1893. The communication set forth the aims and advantages of such a congress, and proposed an organization for preliminary arrangements. The communication was accepted, and it was voted that the President should appoint from the members of this society representatives who should attend a preliminary meeting and report its action to this society. The President was requested, by a unanimous vote, to be one of the representatives.

It was moved that a committee of three be appointed by this society to meet committees of three from each of the societies of Mechanical, Mining and Electrical Engineers to discuss a scheme of affiliation. This motion was laid on the table and the business session adjourned.

The convention reassembled and selected the following Nominating Committee: A. M. Wellington, W. B. Franklin, Charles Paine (chairman), M. L. Holman and G. Bouscaren, representing, respectively, the first, second, third, fourth and fifth geographical districts, which were arranged as last year.

J. E. Watkins presented a paper on "The Beginnings of Engineering, with Special Reference to Early Engineering science in America." Lack of time prohibited the reading of a great part of the paper. The author gave a resumé of the development of engineering in different countries, and mentioned various special works—an ancient aqueduct tunnel in Judea simultaneously constructed from both ends; the first Roman tramways; the first United States canal, in Orange County, N. Y.; the establishment of West Point; the act of Congress in 1794 for employing French engineers here—and traced the evolution of engineering instruments of precision and the growth of engineering societies, and concluded by saying that in America the engineer typifies the restless progressive practical spirit that has made this country what it is.

Discussion. — Clemmens Herschel said that John Smeaton first signed himself "Civil Engineer," and should be considered truly the first civil engineer; he was also the first expert witness.

Don J. Whittemore told of using, over 40 years ago, one of the first four transits made by Young, and how a large transit, ordered about that time from England, was not provided with a revolving telescope, and a second telescope was therefore inversely mounted on the same axis.

C. P. Bassett presented a paper on "Inland Sewage Disposal, with Special Reference to the East Orange, N. J., Works." The author exhibited maps and photographs and briefly described the conditions, construction, operation and efficiency of the works described, which have been illustrated in THE ENGINEERING AND BUILDING RECORD.*

Discussion.—Question (in reference to the amount of chemicals, etc., advised by Mr. Bassett and not adopted in the sewage treatment,) "What would your proposed improvements in chemicals cost?"

Answer: "About $4,000 a year."

Saturday evening the most of the members and guests of the convention went by special train to Altoona, where they were given a reception by Mr. and Mrs. Theodore N. Ely.

MONDAY MORNING SESSION.

At the opening of the Monday morning session the secretary read an abstract of a paper on the "Littoral Movements of the New Jersey Coast," with remarks on beach protection and jetty reaction by L. M. Haupt, M. Am. Soc. C. E., illustrated by maps and photographs. It discussed the subject at length under the following heads: Resultant direction of drift; predominating forces causing movement; angular wave action; reaction *vs.* velocity; normal scum in tidal inlets; enormous deductions; decriptions of special localities. The Node: practical applications; shore protection; insular wave breakers, and reaction.

Discussion.—F. Collingwood: "At Ocean Beach, N. J., I have frequently observed a constant travel of the beach material from south to north: this was also the case during a violent northeast storm."

J. B. Francis: "This wave action was visible at Seabright, N. J., last year, and was not confined to storms, but operated continuously. A similar motion is given to floating objects, which, on a still day, I estimated to move 10 feet a minute."

Prof. O. H. Landreth presented a paper on "The Electric Street Railway System of Nashville, Tenn," in which he noted its remarkably rapid development and extension resulting from the change from mules to electricity. There are now 64 miles aggregate length of track and over 100 cars. The overhead single trolley system was employed. The power developed was 670 nominal electrical horse-power at 500 volts pressure. He described the plant, its details and operation, estimating by three different methods the total amount of power developed, and gave data of the effective power, cost of production, etc.

---

* Pages 87, 107, 117, and 150, Vol. XIX.

Discussion.—J. F. Crowell: "Have you worked out the return of power?"

Professor Landreth: "Only by assumed data."

F. Collingwood: "Have they found electricity more economical than mules?"

Professor Landreth: "Yes, greatly. The operating expenses are very little increased, and the receipts are nearly doubled, both by expansion of the line and increased speed, which induces people to ride for pleasure."

Oberlin Smith: "Dynamometer tests of the cars would be valuable. Have any cars been provided with single instead of double motors, and what is the maximum grade?"

Professor Landreth: "The maximum grade is 8 per cent. There are several 6 and 5 per cent. grades."

Mr. Fava: "In Washington, D. C., a new system is soon to be built having a main circuit and local ones with connections about 90 feet apart. This system has given good results on a 2,000 foot line, and is economical in construction, the cable, trolley, wires, yokes, etc., being on top of the ties and very accessible."

C. B. Brush read a communication on "Water-Works" from F. E. Siekels, which consisted mainly of a description, with illustrations, of some important machines, etc., of his construction, including a steam steering apparatus, a machine for cutting holes in pipes, a watertight pressure regulator valve, now in use by the Kansas City Water-Works, and an air vessel for a direct acting pump, designed to secure the best possible vacuum and promote smooth working.

The secretary read a paper N. W. Eayers on "The Ventilation of Tunnels." The author discussed two methods of removing smoke and gases from tunnels, by natural and by mechanical means. The first operates by producing circulation by temperature and barometric differences, and does not influence short tunnels with their ends at the same levels, but where the engine acts notably as a piston. Ordinary ventilation requirements only necessitate the clearing away of smoke in a time less than the headway of trains. The Hoosac Tunnel is the most important example in this country of natural ventilation. It has a shaft over 1,000 feet deep with connecting galleries at the center, and in winter has closed doors at the ends, and near them warming furnaces to prevent freezing of the atmospheric moisture. The St. Louis Tunnel has a ventilation stack 130 feet high, and a fan house and fan near its center. A description was given of their duty and details and of recent anemometer tests of the circulation of the air. In America natural ventilation so far proves sufficient for the mountain tunnels. In Europe artificial ventilation is most developed in England. In the Mersey Tunnel fresh air is admitted at stations from an auxiliary parallel air tunnel, and the circulation is here, as in several other English tunnels, maintained by fans of from 30 to 40 feet diameter. The conclusion was that successful ventilation lies chiefly in keeping smoke and gas out of the tunnel, instead of admitting and then removing it.

The secretary read by title a paper by F. A. Velschow, on "The Cause of Trade Winds." Meteorological changes were explained and illustrated by charts, and the following conclusions deduced: The surface air becomes dry by resting over the large arid zone lying north and south of the equator, and is formed into cushions of dry air which are ultimately thrown westward over the surface of the oceans. By getting cooled down over the sea surface the dry air appears there as centers of high pressure which are kept up or fed by the continual flow of dry air from land which circulates round these centers of high pressure. The trade winds in each of the five oceans is, therefore, each of them one continual current of dry surface air issuing from a dried-up land district lying to the east of them. The direction of the circulation does not depend upon the earth's rotary motion, but upon the interposition of the centers of high pressure and the corresponding dried-up land districts, the former always lying a little further from the equator than the latter.

The secretary read by title a paper by Charles E. Emery, on "Observations on the Forth Bridge," in which the author describes the location and conditions of the bridge, giving principal dimensions and data, and describes details, construction, erection and plant, adding records and diagrams of temperature movements of the trusses.

A paper by Robert Moore, on "Some Experiments on Anchorage of Iron Bolts in Rock," another by Onward Bates, on "Truss Bridges," and another by W. E. Worthen, on "Steam Heating," had been announced, but were not presented to the convention.

The secretary read a paper on "The Turn-Table on the Main Track of the Silverton Railroad in Colorado," by C. A. Gibbs. The author described this railroad as the steepest, crookedest and best paying one in Colorado. It traverses a very rough country, and had to run over a switch back, for whose operation this turn-table in the main track is necessary for the engine. The train runs by gravity both ways to the turn-table.

John Bogart presented a paper and drawings describing the repairing of a break in the Champlain Canal in New York. A small stone culvert with foundations some distance above bed rock, but in apparently good material, carried a little stream under the canal. At this point the vertical wall of the canal on the tow-path side suddenly gave way and was carried out by the water of a four mile level. The break was repaired in the usual manner by a timber crib, puddled and sheet piled, but in a day or two there was another break on the opposite side of the canal, and as the ground under the culvert was evidently honeycombed, sheet piling was driven to refusal across the canal above and below the break and in this section a timber aqueduct was built with vertical walls, wings and a puddle lining, thus bridging the treacherous culvert. In making the concrete used stone was lacking but was replaced by coal from a boat stranded in passing. The work was rapidly executed from materials at hand and has proved satisfactory.

The paper was briefly discussed by P. F. Brendlinger, J. F. Crowell and A. N. Snyder.

The regular papers having been finished A. N. Snyder, C. E., of the Pennsylvania Railroad Company, gave, by request, a very interesting account of the history and construction of the South Fork Dam, illustrating it with maps, profiles and blackboard diagrams. A very animated and interesting discussion followed on the failure of the dam last year and the destruction in consequence of the Pennsylvania Railroad viaduct bridge No 6 in the Conemaugh Valley about two miles below the dam, which W. H. Brown, Chief Engineer of the Pennsylvania Railroad Company, attributed to undermining and failure of one of the abutment foundations which, in compliance with State specifications, had been built on a timber platform which the rebuilding of the structure showed to have been only 4 feet above bed rock. Other opinions were advanced to the effect that the failure was due to the impact of the flood wave, to the ramlike effect of floating debris, etc., and the general theories of flood wave form and motion and the causes and manner of failure of the South Fork Dam, with descriptions of its former and present appearance, were given by J B. Francis, M. J. Becker, P. F. Brendlinger, J. F. Crowell, C. B. Brush, Col. W. E. Merrill, Mr. Snyder and others.

With this session the convention closed.

Monday afternoon many of the members and guests, through the courtesy of the Pennsylvania Railroad Company, took a special train to Altoona and there visited that company's extensive shops, while others made an excursion to the site of the South Fork Dam. Tuesday morning the most of the Eastern members who remained returned by special train to New York.

THE ATTENDANCE.

The following members and guests were present at the convention:

William L. Abbott, Pittsburg, Pa.; W. A. Aiken, Mt. Vernon, O.; Latham Anderson, Miss Anderson, Cincinnati, O.

Max J. Becker and three ladies, Charles Blackwell, W. A. Ballard, A. H. Browne, A. F. Brown, Pittsburg, Pa.; M. F. Bonzano, Mrs. Bonzano, W. H. Brown, Philadelphia, Pa.; G. Bouscaren, Cincinnati, O.; William Henry Baldwin, Mrs. Baldwin, P. F. Breadlinger, Mrs. Breadlinger, Yonkers, N. Y.; W. F. Booth, Poughkeepsie, N. Y.: Charles B. Brush, John Bogart, Mrs. Bogart, Miss Bogart, Miss E. G. Crans, W. A. Brackenridge, New York City; O. F. Balston, Mrs. Balston, Brooklyn, N. Y.; Thomas W. Baldwin, Mrs. T. W. Baldwin, Miss M. J. Baldwin, Miss C. A. Baldwin, Bangor, Me.; M. L. Byers, Mahoningtown, Pa.; A. Bonzano, Mrs. A. Bonzano, Hubert Bonzano, Mrs. Bonzano, William H. Burr, Phoenixville, Pa.; C. Ph. Bassett, Newark, N. J.; John W. Bacon, Mrs. Bacon, Danbury, Conn.; C. M. Bolton, Washington, D. C.

J. Foster Crowell, F. Collingwood, New York City: O. Chanute, Chicago, Ill.; W. C. Cushing, Zanesville, O.; Amory Coffin, Mrs. Coffin, Phoenixville, Pa.; H. Wadsworth Clarke, Syracuse, N. Y.; Mendes Cohen, Mrs. Cohen, Miss Cohen, John Cassard, Baltimore Md.; Miss R. H. Cole, Boston, Mass.

Harry G. Darwin, Stancliffe B. Downes, Miss Bazena T. Downes, New York City; Paul Didier, Charles Davis, Miss A. H. Davis, Allegheny City, Pa.; F. G. Darlington, Mrs. Darlington, Indianapolis, Ind.; John B. Duncklee, Mrs. Duncklee, Washington, D. C.; James G. Dagron, Baltimore, Md.; J. M. Davis, Philadelphia, Pa. Charles B. Dudley, Altoona, Pa.; G. S. Davison, Mrs. G. S. Davisson, A Dempster, A. Dempster, Jr., Pittsburg, Pa.

Theo. N. Ely, Altoona, Pa.; Henry T. Eddy, Cincinnati, O.

James B. Francis, Lowell, Mass.; Frank L. Fuller, Mrs. Fuller, Boston, Mass.; Desmond FitzGerald, Brookline, Mass.; J. Foster Flagg, Brooklyn, N. Y.; Burr K. Field, East Berlin, Conn.: Clark Fisher, Trenton, N. J.; E. Fisher, Mrs. Fisher, Detroit, Mich.; W. L. Ferguson, Baltimore, M. D.; A. P. Folwell, A. Fteley, New York City; F. R. Fava, Jr., Washington, D. C.

Charles E. Goad, Toronto, Can.; Bernard R. Green, Washington, D. C.; Miss E. L. Griffen, Phœnixville, Pa.; Edward B. Guthrie, Mrs. Guthrie, Buffalo, N. Y.; Carl Gayler, St. Louis, Mo.

S. S Haight, Samuel Garlton Haight, West Farms, New York City; Clemens Herschel, Mrs. Herschel, George R. Hardy, Mrs, Hardy, New York City; K. Emil Hilgard, Cincinnati, O; Caspar Wistar Haines, Mrs. Haines, Miss Haines Philadelphia, Pa.; Peter C. Haines, Washington, D. C.; W. M. Hughes, Alfred E. Hunt, Mrs Hunt, Pittsburg, Pa.; A. C. Hippey, Altoona, Pa.; R A. Hale, Mrs. Hale, Lawrence, Mass.; W. E. Hoyt, Rochester, N. Y.

Thomas H. Johnson, Mrs. Johnson, Pittsburg, Pa.; C. L. Johnson, Albany, N. Y.; J. B. Johnson, St. Louis, Mo.

William B. Knight, Mrs. Knight, Kansas City, Mo.; Walter Katté, Mrs. Katté, Miss Katté, New York City; George W. Kittredge, Gustave Kaufman, Pittsburg, Pa.; Paul S. Kiny, Buffalo, N. Y

Thomas D. Lovett, Cincinnati, O.; Albert R. Leeds, Hoboken N. J.; Olin H. Landreth, Nashville, Tenn.; Thomas B. Lee, New York City; D. Jones Lucas, Mrs. Jones, Philadelphia, Pa.; W. B. Leeds, Mrs. Leeds, Richmond, Ind.

Henry C. Meyer, T. Spencer Miller, Lincoln Moss, Mrs. Moss, New York City: T. H. McCann, Hoboken, N. J.; H I. Miller, Mrs. Miller, Louisville, Ky; Henry G. Morris, Mrs. Morris, Stephen Morris, Philadelphia, Pa.; William Metcalf, Mrs. Metcalf, Pittsburg, Pa.: H. D. Morse, Wilmington, Del.; W. E. Merrill, Mrs. Merrill, Cincinnatti, O.; R. H. McKee, Washington, D. C.: Mace Moulton, East Berlin, Conn.

George B. Nicholson, Covington, Ky.; Edward Nichols, Pittsburg, Pa.

F. S. Odell, Mrs. Odell, New York City; Frank C. Osborn, Cleveland, O.; W. A. Osbourn, Buenos Ayres.

Robert E. Pettit, Altoona, Pa.; Henry G. Prout, New York City; Charles Paine, Robert Pitcairn, Pittsburg, Pa.; W. A. Pratt, Wilmington, Del.; John A. Partridge, Washington, D. C.; George W. Parsons, Mrs. Parsons, Harrisburg, Pa.; W. A. Pike, Minneapolis, Minn.

P. C. Ricketts, Troy, N. Y.; Thomas Rodd, Pittsburg, Pa.; J. R. Richards, Mrs. Richards, Boston, Mass.; Percival Roberts, Jr., Philadelphia, Pa.; J. Ramsey, Jr., Cincinnati, O.; Benjamin Reece, Chicago, Ill.

William P. Shinn and Miss L. A. Meade, R. H. Soule, Pittsburg, Pa; Henry B. Seaman, Brooklyn, N. Y.; Frank W. Skinner, Horace Skinner, New York City; C. C. Schneider, Mrs. Schneider, Mrs. W. J. Cole, S. L. Smedley, Miss J. L. Smedley, Philadelphia, Pa.; Oberlin Smith, Mrs. Smith, Bridgeton, N. J.; J. Parker Snow, Woonsocket, R. I.; C. L. Stroebel, Chicago, Ill.; J. Guilford Smith, Mrs. Smith, Buffalo, N. Y.; Reuben Shirreffs, Paterson, N. J.; F. L. Sheppard, Altoona, Pa.; R. B. Stanton, Denver, Col.; Henry Szlapka, Phœnixville, Pa.

John Thomson, Mrs. Thomson, Stevenson Towle, L. L. Tribus, Calvin Tompkins, G. H. Thomson, A. W. Trotter, New York City; Bushrod W. Taylor, Mrs. Taylor, Louisville, Ky.; George E. Thackray, G. E. Thackray, Mrs. G. E. Thackray, Johnstown, Pa.; E. B. Taylor, Mrs. Taylor, Pittsburg, Pa.; M. M. Tidd, Miss A. S. Tidd, Boston, Mass.; M. W. Thomson, M. Trump, Altoona, Pa.; T. K. Thomson, Ceredo, W. Va.

Joseph Wood, B. L. Wood, Jr., W. G. Wilkins, Mrs. W. G. Wilkins, Victor Wierman, Pittsburg, Pa.; A M. Wellington, New York City; Fred. C. Weir, Cincinnati, O.; J. Elfreth Watkins, H. M. Wilson, Washington, D. C.; D. J. Whittemore, Mrs. Whittemore, Milwaukee, Wis.; F. M. Wilder, Indianapolis, Ind.

ENDURANCE OF IRON IN THE KIEFF BRIDGE.

IT appears by the excerpt minutes of proceedings of the Institution of Civil Engineers that tests have recently been made of wrought iron links that were used 40 years in the Kieff Suspension Bridge, and also of spare links manufactured with those put in the structure but never used. The members were 1 by 12 inches and 12 feet long, and four specimens (A) 1 by 1⅛ by 8 inches were cut longitudinally from a link taken from the structure, and as many (B) from one of the unused duplicates. A 4-inch tranverse test piece (C and D) was also cut from each member.

Single tests of C and D and the means of four tests each of A and B gave results as follows:

Specimen	Tons per Square Inch.		Per cent. of Elongation.	Per cent. of "Contraction."
	Tensile Strength.	Elastic Limit.		
A	21.8	11.1	14.05	17.35
B	22.2	11.93	13.42	18.75
C	14.9	.....	2.1	1.6
D	17.32	.....	6.0	6.8

DESIGNS FOR THE GREAT LONDON TOWER.

THE Committee of Award in the competition for designs for a great tower in London, instituted by the Tower Company, has made its report, giving the first and second prizes to the designs shown in the accompanying illustrations and numbered, respectively, 1 and 2. A third design, given honorable mention, was that of Max am Ende, illustrated in the issue of this journal of May 17.

The design shown in Fig. 1, submitted by A. D. Stewart, M. Inst. C. E., J. M. MacLaren and W. Dunn, A. R. I. B. A., all of London, and awarded the first prize of 500 guineas, is for a tower 1,200 feet high, having an octagonal skeleton 300 feet in diameter at the base. It is to be of steel throughout, and fitted with elevators to the top.

The design given the second prize of 250 guineas, submitted by John L. Webster, M. Inst. C. E., and J. W. Haigh, both of Liverpool, is for an octagonal steel tower 1,300 feet high, with a base 470 feet in diameter. Hydraulic elevators are included, and the lower part of the tower and upper platforms are provided with buildings for residences and other purposes.

The illustrations and data are from London *Industries*. The report of the committee to the Tower Company is as follows:

Gentlemen:—Having completed our investigation of the competitive designs for the proposed tower, we now submit our report. Invitations to compete were advertised on October 23, 1889, and 68 designs were sent in. We met to consider these designs for the first time on March 15 last. Every drawing has been carefully examined by the majority of the committee repeatedly, and while on exhibition at the Drapers' Hall (where the fullest opportunity was afforded of comparing the respective designs), we devoted an entire day there to the work, and throughout have given the most detailed consideration to the question before coming to a final decision as to the award of prizes. The designs were of very varying merit, and although there were good points about many of them, we must confess to a feeling of disappointment on the whole as to the result of the competition, there being no single design which we could recommend as it stands for execution. In justice to the competitors, it must be remembered, however, that the existence of the Eiffel tower and the desire to avoid imitations necessarily considerably enhanced the difficulties of the problem, because in the Eiffel tower the most natural and obvious way of combining economical construction and suitable architectural effect had already been appropriated. As a result some of the designs submitted were wildly eccentric or extravagant, while others were marked by an entire absence of architectural merit.

We found little difficulty in eliminating the larger proportion of the designs, but the final award was not arrived at without repeated and prolonged consideration. Confining ourselves to the designs properly worked out by competent men, we found that, in some cases, the chief consideration had been given to economical construction and in others to architectural effect In other words, some designers approached the problem from the point of view that the main thing was to get 1,200 feet above the ground with a form of tower which, having a fairly good outline, was specially adapted to resist wind pressure and other stresses with the minimum weight of steel, while others adopted the opposite view, namely, that the primary object was to get the best architectural effect without special regard to economy in construction or general practicability. In comparing the designs, we endeavored to do the competitors justice by judging of the merit of their work from the point of view adopted by themselves, and we also gave weight to the amount of time and care which had been devoted to the elaboration of the designs and calculation of tresses and estimates. After very careful consideration, we have decided to award the prizes as follows: First prize (500 guineas), to Messrs. A. D. Stewart, J. M. MacLaren and W. Dunn, 21 King William Street, Strand, joint authors of design No. 37; second prize (250 guineas), to Messrs. J. J. Webster and T. W. Haigh, 67 Lord Street, Liverpool, joint authors of design No. 51.

It is unnecessary for us to set forth the reasons of our decision in detail or to classify in the order of merit designs for which no prizes are available, but the committee desire to state that they consider the design No. 50, by Mr. Max am Ende, deserves honorable mention.

We are, gentlemen, your obedient servants,

E. H. CARBUTT, Chairman,
FREDERICK BRAMWELL,
B. BAKER,
E. J. HARLAND,
ALEX. B. W. KENNEDY,
C. LIDDELL,
J. F. MOULTON,
THOMAS VERITY.

PRIZE DESIGNS FOR A TOWER IN LONDON.

WATER-WORKS FOR GALT, ONT.

WILLIS CHIPMAN, civil and sanitary engineer, of Toronto, Ont., has just made a report to the Mayor and Council of the town of Galt, Ont., on a proposed system of water-works. After reviewing the various sources of supply he advocates Sudden's Lake as the source, to be supplemented from springs when the necessity arises. This contemplates a gravity system, as the elevation of the lake is sufficient to give a pressure of fifty pounds to the inch. He thinks that ultimately it will be necessary to put in pumping machinery to maintain a sufficient fire service. The estimated cost of the work is $125,000, made up as follows: Distribution system, $70,000; purchase and improvements, $3,000; 16,000 feet of mains $32,000; building, $6,000; pumping machinery and boilers, $5,000; engineering and contingencies, $9,000. Mr. Chipman commends the authorities for deciding to build the works themselves and publishes a table of towns in Ontario that have their own works "as an investment, and are paying good dividends."

IMPROVEMENT WORKS ON THE RIVER RHONE.*

THE works described in these articles are still in progress, but as portions of them have been in existence some time and stood the test of both floods and droughts, the success of the complete scheme seems assured, and the author thinks a similar course of treatment applicable to other similar rivers.

The course of the river is divided into three sections:
(1) Above Lyons 120 miles not navigable.
(2) Below Lyons to Arles, 175 miles, navigable.
(3) Below Arles to the sea estuary, 30 miles, navigable.

The regime of the river is described in considerable detail. The main feature of it is the fact that very heavy floods occur from the melting of the snows of the Swiss mountains where the main stream takes its rise, modified by the fact that the principal affluents are not snow-fed, and therefore do not coincide with the main stream in their periods of flood. The bed of the river is of gravel easily eroded, varied at a few points by isolated rocks emerging from the bottom. Until the new works were undertaken, every flood led to a new channel being opened in one part or another of the stream. The object of the work has been to fix the channel of the river and put an end to erosion of the banks and bottom, and the result has so far been most satisfactory. A longitudinal section of the river in any part shows an alternation of deeps and shallows, the deep occurring in the middle of a curve (in plan) at its outer side, and the shallow at a point of inflexion between two successive curves. The author explains how isolated dredging in the shallows reduces the level of the reach above, and generally tends on the whole to reduce the navigable depth rather than increase it. Illustrations are given of the very large variations in velocity of flow that exist in short distances depending on the changes of depth, the curvature of the channel, and other causes, and of the tendency of these variations to disappear as the river rises. The effect of dredging in one of the shallows is to lower the water level and diminish the velocity at that point, and the lowering of level extends through the next reach upwards to the nearest shallows above at which the slope and velocity must therefore be increased and the depth of water diminished. Similar effects are shown to follow in many cases from an isolated embankment narrowing the stream in a shallow. The first effect is of course to raise the level in the shallow. This increases the velocity and sets up an erosion of the bottom which goes on till equilibrium is restored. The net result is a water level which will in general be lower than the primitive level over a great part of the distance affected by the training wall and a diminished depth of water for navigation. As an illustration of these effects a description is given of a certain length of about six miles of the Rhone, on which various isolated embankments were made at different times, between 1858 and 1874, showing that while the immediate effect was beneficial, the indirect results were such as to diminish the available depth in the end. It is seen therefore to be essential, in disturbing the conditions of a river bed liable to erosion, to determine what the condition of equilibrium will be after the new works have produced their full effect, and to make sure that a remedy directed to a specific evil will not produce greater evils elsewhere.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

LAKE CURRENTS AND SEWAGE DISCHARGE.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: The preliminary report of Mr. Rice, late City Civil Engineer of Cleveland, on current observations in Lake Erie is of more than ordinary interest because the subject of lake currents has not received much attention, and a great deal of the experience is either fragmentary or not published. Four years ago a similar series of experiments (results not published) was made in Lake Michigan opposite Chicago to ascertain the probable dispersion of sewage if discharged into the lake. Generally three floats were used at each station, one at the surface, another at mid-depth, and a third near the bottom. A large number of bottle floats were also used, single and double, the lower one at the starting point being placed 10 to 20 feet deep. The general results were similar to those since found at Cleveland. Unless affected by local irregularities of the shore the currents were found to go substantially with the winds in water of moderate depth, and to respond quickly to any change. In deep water the surface currents also soon changed with the wind, but those at mid-depth and at the bottom did not generally partake of the same motion, sometimes being more than 90 degrees different, which is probably due to the equalization caused by the heaping of the water on the lee shore. Inasmuch as the lake currents are so variable we can, for purposes of sewage disposal, rely only upon dispersion and dilution of the foul matter, but not upon absolute removal from any given localities. Mr. Rice's suggestion of ponding the sewage near the shore during unfavorable winds is a new one I think. Undoubtedly the expedient would be efficient in many instances, although it might cause some deposit. It is conceivable, however, that the large area or mass of ponded diluted sewage, after flowing into the lake, could, by a sudden return of the unfavorable wind, reach the water intake in a less desirable condition, because less dispersed, than if the sewage had been continuously discharged into the currents passing the head of the proposed embankment. It seems to me that the least objectionable method of discharging sewage into our lakes is to screen it thoroughly, if no better partial purification can be afforded, to get it into currents as soon as possible, and to keep the outfall as far from the water intake as as local conditions and finances will show to be prudent.

RUDOLPH HERING.

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

No. XCV.

(Continued from page 408, Vol. XXI.)

REINFORCING AN IRON FLOOR.

FIGURE 1 is a diagram of the iron work of an upper floor in a large sugar refinery.

N N are cast-iron columns carrying the longitudinal girders N N, etc., which support the transverse girders K K, etc., on which the wooden floor is laid.

Figure 2 shows elevations of some of these transverse and longitudinal girders with loads concentrated on the iron pedestals J J. All these original girders were 15-inch 200-pound rolled beams, and were in nearly every case used in pairs. A few single beams were used, but they are not distinguised in Fig. 1, where all the original girders are shown by full double lines for uniformity. This floor was very heavily loaded, and after a time it was determined to reinforce it with additional beams, which were required to be set without disturbing the floor and could not much diminish the headway of the story below.

Under these conditions it was decided to support each transverse girder K at its center by longitudinal beams, A A, etc., and B B, etc., which are carried on cross-girders connected to the old longitudinal girders L L, etc., very near the columns.

If the load had been uniformly distributed, each girder K would have been relieved of one-half its total load, and three-fourths of the maximum bending moment; the loads being, however, irregularly concentrated, the results were not exactly in this ratio, but were in most cases nearly as good.

In the case of each longitudinal girder L, about half the load was removed from its bearing with K, and returned at a point as close as possible to the end, thus greatly reducing its bending moments. All the new girders are shown by single broken lines. A A, etc., and B B, etc., are all 20-inch steel I-beams, weighing 272 pounds per yard. A A, etc., are shown in Fig. 8; they are set parallel to the old girders L L, etc., and with their upper flanges in a horizontal plane about ½-inch below that of the top flanges of the girders L L, etc. They are connected to the webs of the new cross-girders by the angles M and M. B B, etc., are the same as A A, etc., except that the angles M are omitted at one end, which has a bed plate for bearing on the wall.

The new cross girders C^1, C^1, D, E, H, I, O, P, P^1 and Q, shown in Figs. 3 to 7, inclusive, are set with their top flanges in the horizontal plane of the top flanges of A and B.

Figure 3 shows an elevation of the girder D and sections at Z Z and Y Y.

Figure 4 shows a end and side elevations and section at Z Z of the girder H.

The girders I are like H (Fig. 4), except that one end is made as shown in Fig. 5 so as to rest on the wall. The girders E are like D (Fig. 3), except that one end rests on the wall and is made similar to that shown in Fig. 5. The girders C^1 are like H (Fig. 4), except at the center, which is made as shown in Fig 6. The girders C are like the girders C^1, except that the brackets S S are omitted. The girders P^1 and P are like the girders C^1 and C, respectively, except that one end is made as in Fig. 5. The girder Q is like the girders H (Fig. 4), except that the center is as shown in Fig. 7. The girder O is like the girders C (Figs. 4 and 6), except that one end is made to rest on the suspended seat shown in Fig. 9, where the new cross girders are supported by the old longitudinal girders L, L, etc., they rest on their lower flanges, to which they are accurately fitted by the heavy plates A A (Figs. 3 and 4), shaped in a cast-iron former to exactly fit the angle and fillet of the flange.

After the new girders were all set very careful diagrams were made showing the deflections of the old girders and the clearances between the girders A and the girders K (which was intended to be about ½ inch) at their intersections. It was then calculated what the deflections of both would be under the required distribution of load, and they were sprung apart by 10-ton hydraulic jacks until the clearances between the lower flange of the girder K and the upper flange of the girder A at their intersection equaled their original clearance, plus the required deflection of A plus the difference between the original and readjusted deflection of K. Wrought-iron shims of the exact required thickness were then inserted between the girders K and A, and, the jacks being removed, the girders adjusted themselves to the required loading.

In most places the jacks were applied as shown in Figs. 11 and 12.

Figure 11 is an elevation at V V, Fig. 12, and Fig. 12 is a section and elevation at W, X, Y, Z, Fig. 11. Four pairs of angles C C were placed as shown with one flange vertically against the web of the girder A; the other flanges were milled to exactly fit the lower flange of the girder A at P P, and were connected by cross angles B B, fitting snugly at the top and bottom of A. Brackets D D were riveted to the angles C C, etc., and received the suspenders E E that supported the platform beams F and G on which were carried the hydraulic jacks J J, whose tops engaged the girder K. H H were spacing pieces. As the pistons of the jacks were pumped up they separated the girders A and K* until the shims could be inserted, after which the pressure was removed and the jacks and attachments taken to another point.

A different arrangement was required at the points T, T, T and T (Fig. 1), where each load taken from the old girders K, K, etc., was to be transferred to two new cross girders which received it from a section (A^1) of the girder A that was so short that there was not room for the above described arrangement, and one shown in Figs. 13 and 14 was adopted.

Figure 13 is a section and elevation at V V, Fig. 14, and Fig. 14 is a section and elevation at Z Z, Fig. 13.

---

* There was an initial clearance between these girders which is, for convenience, omitted in all the illustrations.

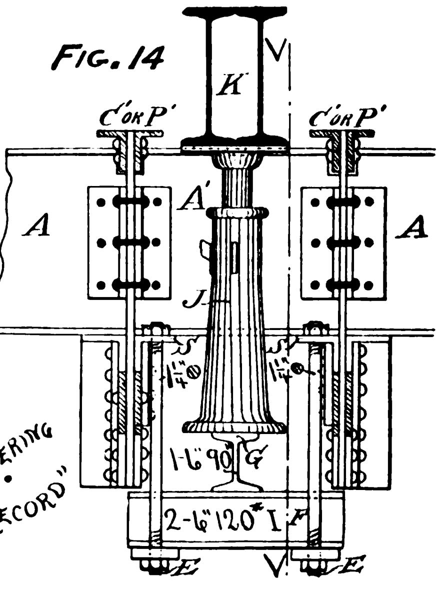

FIG. 14

"THE ENGINEERING • AND • BUILDING RECORD"

Here both jacks J engaged the twin girder K and were seated on the platform beam C that was supported by eight suspender rods E E from the brackets S S riveted to the webs of the new cross girders. In this case, therefore, when the jacks were operated they did not react on the short girder A^1 but caused direct deflection in the new cross girders C^1 and P^1 and in the old girder K.

This reinforcement work was designed and executed by the New Jersey Steel and Iron Company, of Trenton, N. J., which furnished data from which the above description and illustrations have been prepared in the office of this journal.

WATER SUPPLY AT NEW ORLEANS.

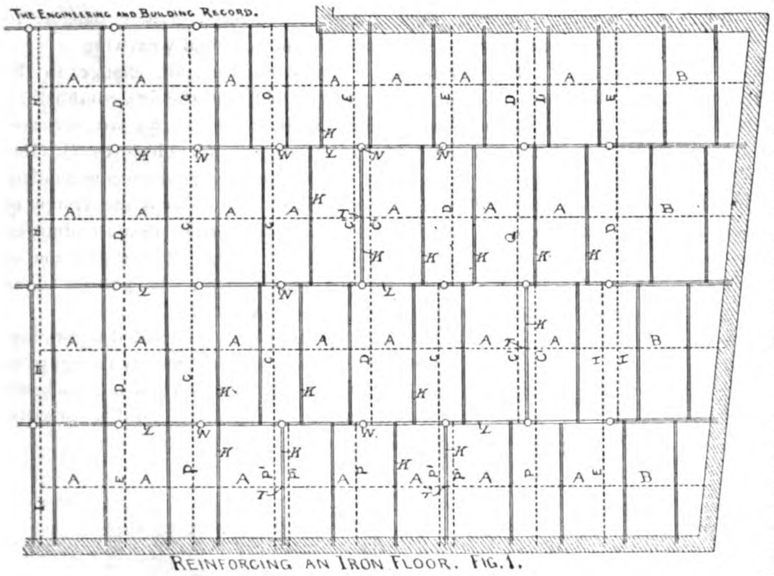
ACCORDING to the recently issued report of the Louisiana State Board of Health for 1888 and 1889, the chief source of water supply in New Orleans is the overground cistern. These cisterns vary in capacity, the smallest holding 1,000 gallons, and the largest from 18,000 to 22,000 gallons. The Charity Hospital has 14 cisterns which aggregate 200,000 gallons. These cisterns are made of cypress staves, belted together with strong iron hoops, and are generally covered on the top to protect their contents from the soot and dust of the atmosphere. A great deal of the latter, however, is swept into them by the first rain after a drought, necessitating frequent cleansing.

In a large portion of the city, particularly the upper districts, Algiers and the suburbs, there are no water mains, and the cistern and well are the only sources of water supply. It is the custom for many families to filter the cistern water, but the majority drink it fresh from the tank, and although impurities occasionally find their way into this water it may be stated that as a general rule this water is healthy and sweet to the taste. Indeed, if the "cut-off," which is sometimes used to receive the first impure washings of the roof, could be put into general use, the water supply, it is thought, would be more wholesome than any other obtainable. The inability to construct underground cisterns in the city is looked upon as a God-send to the people, and it is considered due to this fact that typhoid fever is there so rare a disease.

The hydrant, which supplies river water from the Mississippi, is in common use in the thickly populated districts. This water is used for drinking purposes by many, but its thick sediment of grayish mud is said to preclude it from general use until after the latter has been separated from it. This is not considered as safe or as healthy a water for drinking purposes as cistern water, though there is no evidence that it has ever been the means of spreading epidemic disease.

Among wells, the artesian, driven and dug wells are used for drinking purposes, though there is a law prohibiting the use of dug wells for anything but cleansing purposes. Frequent attempts have been made to enforce this law, and though public opinion is gradually coming to appreciate its meaning, it is stated that a sanitary force fifty times as great as that now available would be powerless to prevent the drinking of the water as long as a well is allowed on the premises.

Many premises contain both hydrants and cisterns, and these are about as numerous as those which contain hydrants alone. The proportion of premises that have cisterns only is to those that have hydrants only as ten to one, a serious preponderance in seasons of long drought.



REINFORCING AN IRON FLOOR. FIG. 1.

Novelties.

Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

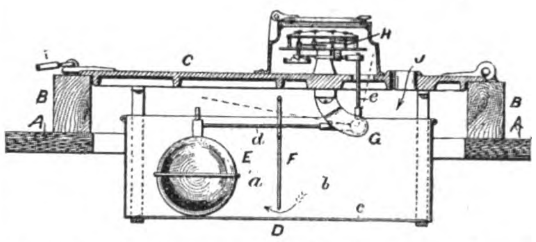
In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course be understood that the selection does not imply indorsement.

WATER CART REGISTER.

THE water cart register illustrated herewith is the invention of S. A. Charles, Superintendent of the Lexington Hydraulic and Manufacturing Company, of Lexington, Ky., and is used upon all watering carts in that place. The device is to be manufactured by the Hersey Meter Company, of South Boston, Mass., and consists of a framework shown in the sketch, marked B, upon which is hinged a cast iron cover C. To the under side of this is attached a pan D, divided into two compartments *a* and *b*, by a partition F, sufficiently removed from the bottom of the pan to allow communication between the two compartments. In the compartment *a* is a copper float E, resting upon the bottom of the pan, and connected by means of a rod *d*, so that it has a fulcrum in a casting G. This rod is extended at the other end of the fulcrum, as shown at *e*, and is connected with a registering mechanism H so that upon the lifting of the float the hands of the registering mechanism are moved so as to indicate the lifting. Directly over the compartment *b* is an inlet hole J in the casting through which the water is directed to the pan.

Water Cart Register



The whole device is mounted upon the watering cart, which is represented at A A, so that the float pan hangs

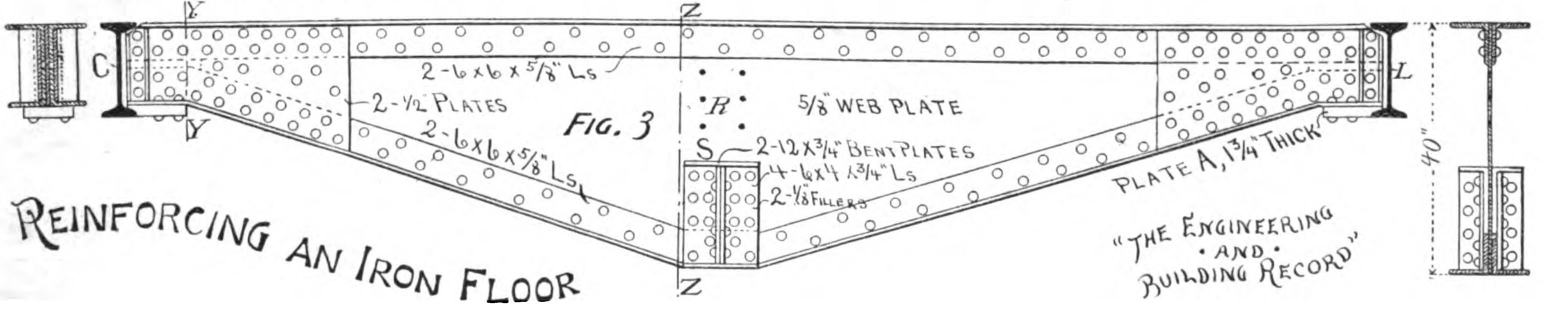


FIG. 3

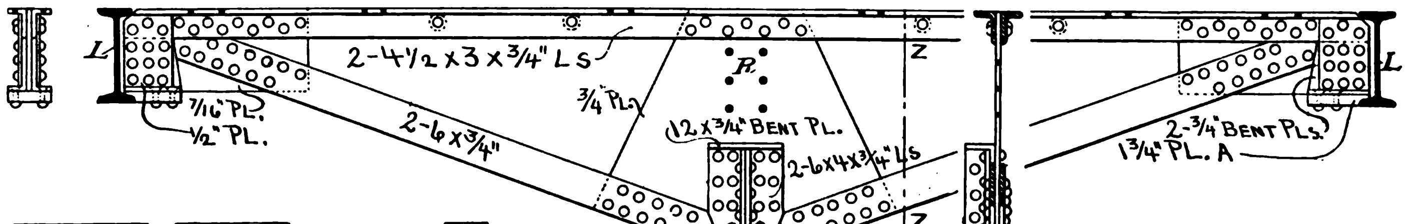

FIG. 4

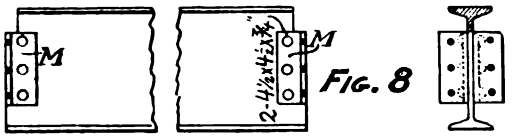

FIG. 8

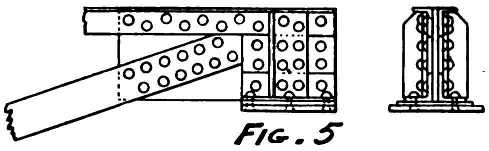

FIG. 5

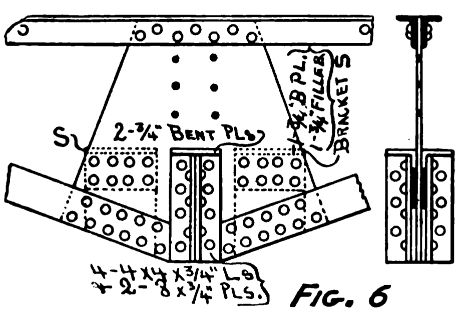

FIG. 6

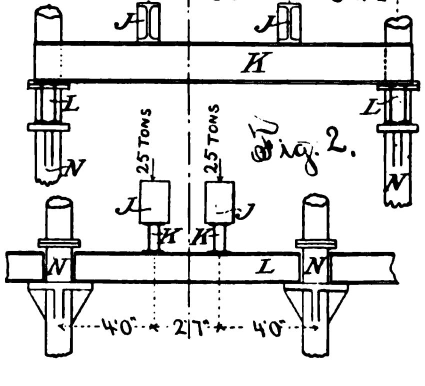

Fig. 2.

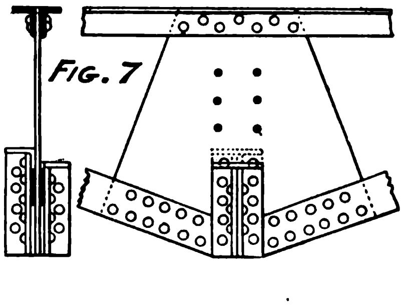

FIG. 7

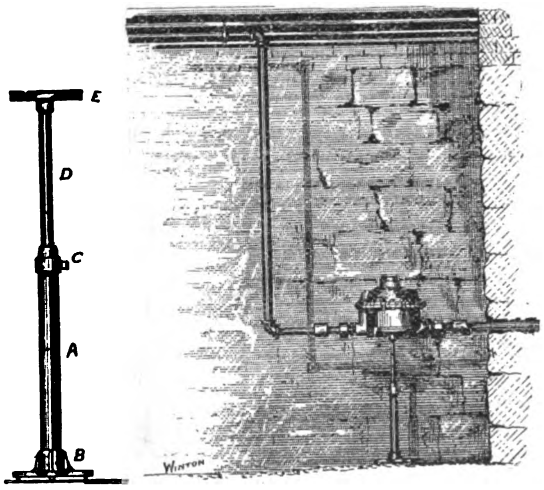
in the cart. The operation of the device is as follows: The supply pipe for filling the tank is placed in the inlet hole J on the top of the casting, allowing the water to pass into the compartment *b*, whence it passes into the compartment *a*, and lifts the float, which causes the register to indicate the inlet of the water. When the pan is filled it overflows into the cart over the sides, and so long as the supply pipe remains, the cart will continue to fill through the overflow of the pan. When the supply is cut off the water remaining in the pan will gradually drain out through several small holes indicated at *c*, and allow the float to return to its normal position. It will be seen that it is impossible for the cart to be filled without recording upon the register. It is necessary that the cart be completely filled each time or it would be to the detriment of the one taking the water. The department knowing the capacity of the tank, and taking the readings of the register, determines exactly the amount of water used by the several carts, and makes the rates accordingly.

The cover upon which the device is secured is locked by a padlock, as shown at *i*, the key of which is retained by the department. The inlet passage J being the only place at which the cart can be filled it is impossible for water to be obtained by the driver of the cart without proper record of it. The cover is large enough to admit of a person getting into the tank, if it requires to be cleaned out, and the whole registering mechanism can be lifted out of the tank with the cover.

ADJUSTABLE WATER METER SUPPORT.

The adjustable water meter support shown in the accompanying illustration was designed by the Hersey Meter Company, of South Boston, Mass., and exhibited by them at the recent Portland meeting of the New England Water-Works Association.

The device consists of a piece of pipe A, to which is secured a casting B, which forms a foot. Upon the other end of the pipe is a casting C, through which a smaller pipe D slides. This smaller pipe has secured to its upper end a casting E, shaped to receive a meter and hold it firmly. The smaller pipe is adjustable up and down, to accommodate meters set at different heights, and is secured by the set screw C.



ADJUSTABLE METER SUPPORT

The device is intended to be used in places where a meter is hung in the pipe, as shown in the sketch, to relieve the weight of the meter from the connections and pipe. It is a simple and neat substitute for a wooden shelf or bracket which it is frequently necessary to build in cellars and other places where meters are set.

THE OTIS ELECTRIC ELEVATOR.

An electric elevator has just been placed on the market by Otis Bros. & Co., of New York City, which is said to be well suited to many places where it has heretofore been impracticable to use such an apparatus. The winding machinery and safety appliances are such as they have been using for many years, but the motor, of which Rudolph Eickmeyer, of Yonkers, N. Y., is the inventor, possesses many novel features and was specially designed for elevator service.

Among the advantages claimed for electric power generally and for this motor in particular are its safety, simplicity, efficiency, the absence of noise, smell, smoke, ashes and heat and freedom from liability to damage by frost or by careless manipulation.

Referring to the illustration, A is the car with the usual safety attachments, running in guides B B and supported by the hoist ropes C C. The other ends of these hoist ropes C' C' wind on drum D from whose opposite side at the same time unwinds the counterweight rope X. E is the hand rope by which the motion of the car is controlled. Its two ends E^1 and E^2 wind on opposite sides of wheel H, which by arm I throws shifting bar M. This by arm Y and the sector and pinion motion at L operates the switch at S which cuts off or changes the direction in the motor Q of the electric current that enters and departs through wires F. When bar M is in mid position the elevator is stopped and the notch N permits roller R to drop into it and weight W on lever Z then applies brake O to the motor shaft, which is not shown. This shaft has an end bearing at P and carries commutator L, passing through motor Q, by which it is driven, and casing T it ends in box U where it carries an endless screw or worm which drives a worm gear in casing V. This gear is attached to the hoisting drum and so operates the elevator.

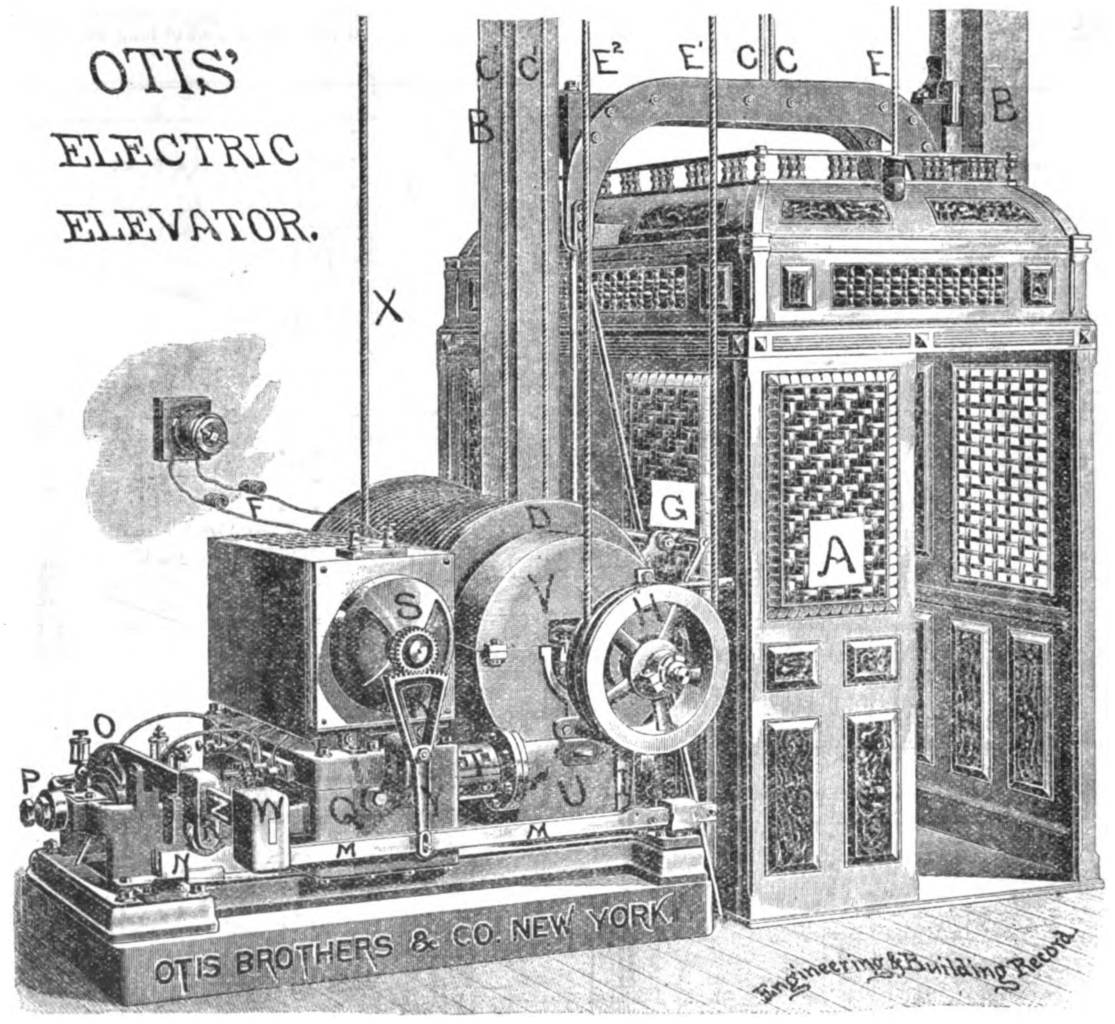
Wheel H is carried loose on the end of the drum shaft, but when the latter has made a certain number of revolutions either way wheel H is carried with it and thus automatically stops the car at either end of its travel.

At G is shown a part of the slack cable stop by which, should the car ever get stuck while descending, the machinery would be instantly stopped and injury to it and the cables prevented.

When it is desired to start the elevator up or down a pull on the hand-rope E, which passes through the car, by the mechanism before described moves shifting bar M, which by moving notch N lifts roller R and weight W and releases brake O, while at the same time the switch sends the electric current to the motor in the desired direction.

If the attendant in stopping the elevator should not get the switch in mid position and by leaving a slight contact run the risk of burning the switch, an alarm or "buzzer" in the car will warn him of the danger, and its noise can only be stopped by getting the switch exactly in the middle so as to cut the current entirely off.

A special attachment causes the electric current to be gradually turned on or off so as to avoid any shock in starting or stopping, and the motor is so arranged as to operate at a uniform speed in either direction and at the same time to avoid waste of power by automatically adjusting the strength of the current to the work to be done, while its external magnetism is so slight that a watch may safely be laid on its casing.



SANITATION IN MELBOURNE.

A royal commission appointed two years ago to investigate the sanitary condition of Melbourne, Australia, has just made its final report, accompanied by reports of three engineers submitting sewerage schemes. Melbourne itself has but about 76,000 population, but, including suburbs, which are practically a part of the town in sanitary matters, it has over 420,000 people. All drainage is into the Yarra River, which winds through the city and suburbs, and the stream is further contaminated by refuse from abattoirs, tanneries, etc., on its banks. The drainage is by open channels in the streets, and even this primitive system is very imperfect. The report says that in many sections the liquid house refuse is allowed to largely lose itself in the soil, that the channels are imperfect and the sewage is everywhere polluting the ground, heavy rains make the nuisance from overflowing very troublesome, and to modify this crude underground drains have been constructed in some places, but it is questionable whether the remedy so applied does not involve greater dangers to health than the open nuisance originally existing.

The commission recommended certain changes in the pan system for temporary relief, and the final establishing of a complete sewerage system. As to this last, schemes were proposed by three engineers, W. Thwaites, G. Gordon and W. F. Bell. Each of the gentlemen recommended, in view of the violent rainfalls, the separate system of sewers, with a small part of the earlier rainfall admitted for flushing purposes, and the complete substitution of water carriage for the pan system, the present open storm water channels to be retained.

The water supply of Melbourne is treated separately, and the suggestions of the report are mostly in regard to purifying it. The water is collected from a large basin in the Yan Yean reservoir, is not filtered, and is not satisfactory in quality.

DOMESTIC PLUMBING HEATING LIGHTING & VENTILATION ENGINEERING

PLUMBING IN THE UNION TRUST COMPANY'S BUILDING.

PART I.—ROOF, SUCTION AND DRIP TANKS AND PUMP CONNECTIONS.

THE Union Trust Company's new building on Broadway, New York City, is about 100 feet front, 120 feet deep, and has 13 stories above the basement. It is designed to accommodate a bank on the first floor and the offices of the Union Trust Company on the second floor, while the upper floors are fitted for offices; a restaurant, kitchen, etc., being built on the main roof.

The plumbing comprises, in general, the hot and cold water supply to the toilet-rooms and to basins in all office rooms, and the drainage from all fixtures. The most of the water is pumped through the 4-inch pipe A, Fig. 1, to the iron roof tank T, that is about 14 feet square and 8 feet 6 inches deep, and is closed by iron plates over the top. The tank rests on wooden sills B B B, laid in a sheet iron-lined safe S, which is supported by wooden beams C C C, resting on the floor directly under the sills B B B. The tank overflows through a 4-inch pipe D to the roof gutter, and may be emptied, also to the roof gutter, through a key valve E and 2-inch pipe F. H is a 2-inch supply-pipe to the eighth and ninth floor toilet-rooms, and G is a 4-inch supply pipe to the distribution drums in the cellar. I I are 1-inch vent-pipes to the pipes G and H. J is a vent-pipe from the hot water system, and L is the 1½-inch safe waste, discharging on the roof. M is a wire cable from the tank float operating the index of the indicator in the pump-room.

Water under street pressure is delivered through a 2-inch pipe A, Fig. 2, and ball-cock B to the closed iron suction tank C, about 5 by 5 feet, that is in the cellar near the pumps. This tank overflows through a 4-inch pipe D, which has a trap with a 24-inch seal that is preserved by the constant discharge from the steam drip pipe I. E is a valve for emptying the tank. F and G are 1¼-inch pipes to empty the pump delivery to the tank and the 4-inch supply pipe from the tank to the distribution drums. H is the 4-inch suction-pipe to the pumps.

Figure 3 shows the connections of the special tank pump A and one of the boiler pumps B. H is the 4-inch suction pipe from the tank C, Fig. 2, with a branch E to the pump B. D is the 4-inch delivery pipe to the roof tank with a branch F from the pump B. G is a 2-inch branch connected with the delivery pipe of another steam pump, generally used for the steam boilers. Ordinarily the valves M and N are open, while I is closed, and the tank is filled by the pump A; but if the valves I, K and L are open the pump B can also be turned to the tank, and by opening the valve J the third pump may also be used for the tank in case of fire or in any other emergency.

Figure 4 shows the cellar drip tank A which is simply an iron shell about 6 feet long and 30 inches in diameter to receive the overflow from the suction tank C, Fig. 1, the waste from emptying the pipes of the distribution drums, discharge from drip sinks and cellar drainage, all of which is below the street sewer level. B is a collector from the waste pipes of the floor strainers I I, etc., and the drip sinks. C is the emptying pipe from the distribution drums and D is the emptying pipe from the tank C, Fig. 2. E is an aspirator to which steam can be admitted through the valve F to produce suction and draw the contents of the tank A out through pipe G, which discharges through a branch K to the house drain L that empties into the street sewer. H is a vent pipe to maintain atmospheric pressure in the tank A.

(TO BE CONTINUED.)

HOSPITAL CONSTRUCTION.*

A HOSPITAL is primarily a building devoted to the care and treatment of the sick and injured poor; in its secondary, and scarcely less important function, it is a training school for the teaching of the science and art of medicine and surgery.

Now, in order that both these functions may be performed to the best advantage, it is necessary that large numbers of patients should be brought together in one hospital, for it will easily be seen that the task of administering one hospital for 300 beds will be far easier and less costly than that of administering ten hospitals for thirty beds each, and for teaching purposes the larger the amount of material the better both for teachers and students. The risks, therefore, inherent on the aggregation of large numbers of sick people are, and must be, encountered, because it would be impossible to furnish the necessary medical and surgical aid to the sick poor in any other way. Let us consider briefly of what these risks consist, and how the experience of the past helps us to overcome them. In the first place, it must be remembered that a hospital ward is filled either with people whose condition is that of disease, the exhalations of whose bodies are laden with infection, or with those with open wounds, to the exposed surfaces of which the contact of impure air means the production of a special class of traumatic or wound diseases. In either case it is the contamination of the air of the ward which retards or prevents the recovery of the patients. This contamination of air may be accomplished in several ways: it may either be by overcrowding of patients in the wards, by imperfect ventilation, by improper arrangement of buildings, by defective drainage, or by defective keeping or maladministration.

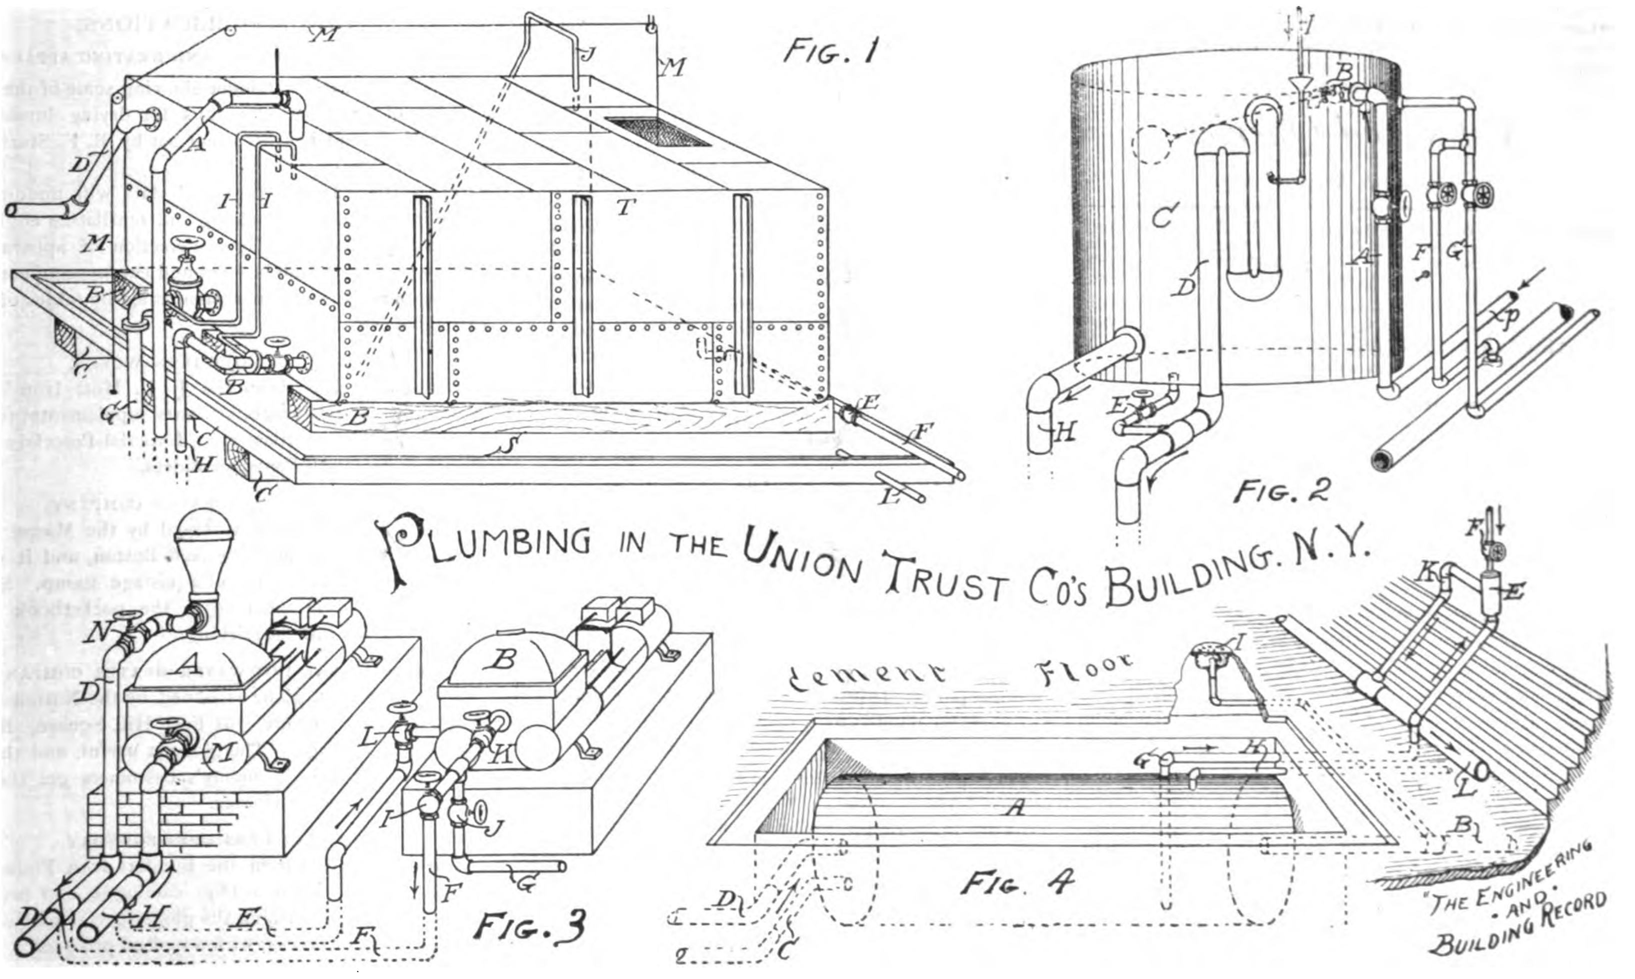
In considering the principles which should guide us in the planning of a hospital, the first question to be determined, assuming that the number of patients and staff and the necessary classification has been settled, is the position of the various buildings in relation one to another. There must be in every general hospital—and it is with this class of hospital only that I am now concerned—at least five separate departments: (1) the administration, which comprises all the purely official and domestic parts; (2) the nurses' quarters; (3) the wards; (4) the out-patient department; and (5) the mortuary. In many important hospitals of recent date these have been again subdivided, and separate buildings provided for kitchen, offices and the operation room. The main fact, however, which I wish to impress is that all these five buildings should be as separate and distinct as it is possible to make them. In most hospitals erected during the last century you will find that every department, including also frequently a laundry, is housed in one building, and that every part of that building is in more or less direct atmospheric communication with every other part. The evils of this arrangement have over and over again been demonstrated, and many such hospitals have been within recent years either demolished or very materially altered, much to the gain of the patients.

The detailed planning of the administration building will necessarily vary according to the size of the hospital, and no very minute rules can be laid down respecting it. I may, however, point out that unless the kitchen offices are placed in a one-story separate building they should certainly be put at the top of the house. There is no practical difficulty attending this arrangement, examples of which may be seen at the Hospital for Consumption, Brompton, the Great Northern Central Hospital and the Hastings Hospital. The provision of ample store accommodation is an important point. It is far better to provide too much store room than not enough, for the difficulty of increasing store room in an existing building is very great indeed. We may now pass on to the wards, which, together with their offices, form the most important part of the building. Formerly a ward was regarded merely as a room into which a certain number of beds were to be put, without much thought being taken of how the well-being of the patients would be affected by the conditions under which they were to be housed.

The essential feature of the pavilion system is that the wards are long rectangular buildings, projecting out usually at right angles to a main corridor. The space between the pavilions should be equal to at least twice the height of the buildings, and the long axis of the

---

* From a paper read by Keith D. Young before the London Architectural Association.



wards should be nearly due north and south, so that the maximum amount of sunshine available should be admitted to the wards. The question of the number of stories admissible in a ward pavilion is one upon which authorities differ materially. In many of the most recent hospitals in France and Germany, and notably in the magnificent hospital at Baltimore, the wards are restricted to one story only. Such a system is obviously a most costly one in the matter of site; and it seems to me that it is to be justified only on the score of really important benefit to be gained. Personally, I am unable to see any sufficient gain to be obtained at all commensurate to the enormous cost involved. But—and this lies at the root of the matter—if two or three stories of wards are to be superimposed, each must be absolutely independent atmospherically of the other—there must be no shafts, whether for staircases or lifts, to communicate the air of one floor with that above.

In considering the internal arrangement of the wards the first point to be settled is the space to be alloted to each patient. Space in a ward is very commonly referred to as cubic space only; but it is equally important to consider floor space, and the distance to be allowed between each bed and its neighbor. Upon this question of space authorities differ widely. In the table given in Mr. Snell's work the floor space varies from 69 feet per bed to 149 feet, and the cubic space from 864 feet to 2,544 feet. The last figures are those of the Hospital of St. Andrew at Genoa, whose wards are considerably over 20 feet high. Now it was the opinion of so eminent an authority on ventilation as the late Professor de Chaumont that nothing is gained by making the height of a ward exceed 12 feet, and in making calculations in actual practice he was accustomed to exclude all space in excess of this amount. You will see, therefore, how important it is to arrange your cubic space in relation to your floor space, and not to increase the one at the expense of the other. In the first place, then, the wall space or distance from center to center of each bed should be determined. In a large ward, say for 20 beds, the space should not be less than 8 feet—8 feet 6 inches or 9 feet by preference. For the width of the ward 28 feet is a good dimension. It allows plenty of free floor space in the center of the ward, which is a point that must always be remembered, especially where clinical teaching is carried on. These figures give a floor space of 112 feet as a minimum. Taking 12 feet as the standard height, you get a cubic space per bed of 1,344 feet. A height of 12 feet will, however, be found, for appearance sake, too low for a ward upwards of 80 feet long, and I think something must be conceded to one's sense of proportion. Having settled the dimensions of the ward, the next step is to place the beds and set out the windows. In some of the plans shown you will see that the beds are arranged in pairs, with one window to every two beds. This plan of coupling the beds has many disadvantages. In the first place, each bed is unduly near one of its neighbors, instead of being placed in the center of its own air space; secondly, the ventilation cannot be so perfect as when each bed has a window each side of it; and, lastly, the beds are necessarily so close on one side to the windows that much inconvenience arises therefrom in the shape of draughts and cold currents of air from the condensing surface of the glass. Each bed, then, should occupy the center of its own air space, and should be between two windows.

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

HEATING SURFACE FOR INDIRECT HEATING.

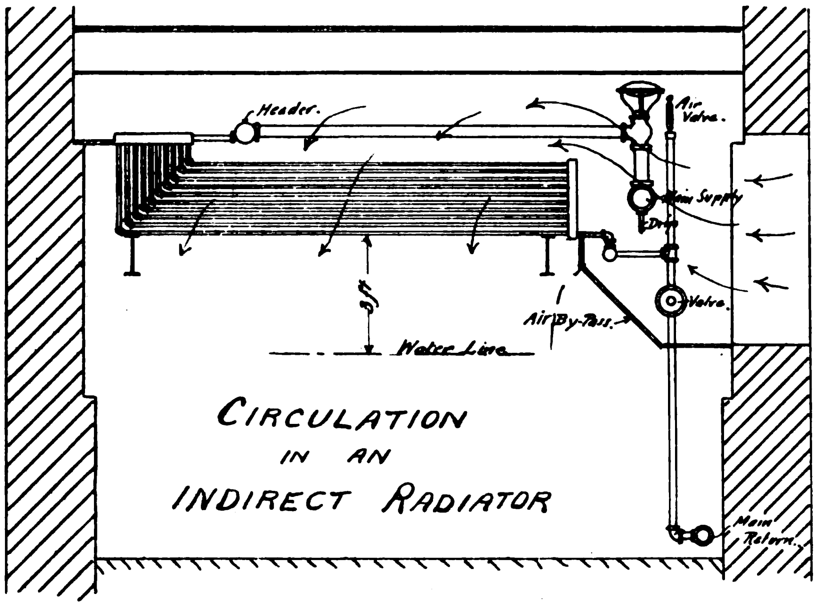
ARCHITECT, of Hamilton, Ont., writes: "Would you kindly give the amount of heating surface required for ventilating purposes by indirect heating where direct heating is used for a dwelling house or public building, and state which is the best kind of radiator, cast or wrought iron, to use for this mode of ventilation? The heating employed is direct by hot water."

[We assume that hot water is, in this case, to be used in the indirect radiators also, though not so stated, and that what our correspondent really proposes to do is to divide up the heating surface for each room between the direct and indirect radiators. The amount of heating surface necessary in the latter will depend upon the amount of air to be supplied to the rooms, and upon the amount of direct radiating surface already on hand or intended to be provided, but in the absence of further data we cannot give a definite answer Generally speaking, however, one square foot of indirect radiating surface, when hot water is used in the ordinary way, will suffice for from 15 to 40 cubic feet of air to be heated in dwellings, offices, etc.; for from 25 to 50 cubic feet in halls, stores, lofts and factories, and for from 50 to 100 cubic feet in churches and large auditoriums. These figures cannot be made more definite, as the exact conditions of the problem are not known. It will be understood that where there is much exposure the lowest estimate should be used, while under more favorable conditions a smaller proportion of surface will do the work.

As to the best kind of radiator, cast iron or wrought iron, we would say that we know of no reliable data on the relative efficiencies of commercial heating surfaces. Both cast and wrought iron are in extensive use, the former most largely.]

CIRCULATION IN AN INDIRECT RADIATOR.

"P. N. K.," Boston, writes: "I inclose a sketch of a fresh air heater made up of 60 miter coils of 1-inch pipe on branch tees. Each coil is 12 feet long by 10 pipes deep; pipes 2½ inches on centers; total heating surface about 2,450 square feet; main supply 7 inches; main section 3½ inches. The heater is divided into sections of 200, 400, 600 and 1,200 square feet, with supply pipes 3, 3½, 4 and 5 inch, respectively. The supply to each miter coil of 40 square feet is 1½ inches diameter. There are to be Johnson diaphragm valves on supply and return of each section.



A fan draws a maximum of 30,000 cubic feet of cold air per minute through the heater. There has been some discussion as to whether there would be a good circulation of steam in this heater and I should be glad to have your opinion on the matter. The water is returned to the boiler by gravity and the boiler power is ample; pressure 5 to 10 pounds. Will the heater clear itself of air in good shape and is there any danger of a freeze up? Would you recommend returning the water by tank and pump instead of by gravity?"

[With a difference of level of only three feet between the water line and the lowest level of the coil we should prefer to return the water to the boiler by a pump, taking the water out of the system as rapidly as it is formed. With a gravity return the arrangement may work satisfactorily, but there is always a possibility that the water will back up into the radiator and give trouble. With a pump return we think there will be no difficulty in securing proper circulation. With an indirect system, more particularly where forced circulation of air is used, as in this case, we would nearly always recommend the use of a pump for the water of condensation. It insures certainty of action and the extra cost of its installation will be found a good investment.]

HEATING BY EXHAUST STEAM.*

THE economy of using exhaust steam for heating shops and factories seems to be very little appreciated, and it is not at all infrequently that we see a direct steam-heating apparatus in use when the exhaust steam from the engine would heat three or four such buildings.

If we have a 10 × 12 engine making 250 revolutions, using steam at 85 pounds gauge pressure, it gives about 25 horse-power. If it is an automatic cut-off engine it will use about 30 pounds of steam per horse-power, or 750 pounds per hour. Expanding four times, the steam at exhaust will be at 10 pounds gauge pressure, and will contain 1,155 heat-units per pound, of which 975 heat-units are available for heating, and the total available heat in exhaust steam per hour is 731,250 heat-units. This, under ordinary conditions, will heat a shop two stories high and 40 × 120 feet, or as large a shop as that of which the engine would run the machinery. However, some may wish to use the exhaust steam for heating the feed water, but in that case, with a good heater less than one-fifth of the exhaust is needed, and besides, by conveying the drip from the heating coils to a hot well the best feed water will be obtained at a high temperature. If one objects to the back pressure on the piston of the engine, let the feed pump or injector be connected to the end of the heating coils when the back pressure can be reduced to zero, but at the University of Michigan there are several exhaust heating coils of 1¼ inch pipe over 100 feet long that do not raise the back pressure more than one pound. It has also been suggested that the condenser, if the engine be a condensing one, might be connected to the end of the heating coils. The vacuum at the back of the piston would then be less, by the amount of friction and resistance in the coils, than if the condenser were closely connected, and the temperature in the coils would be that due to the pressure, so that the coils would need to have more surface, and on that account the arrangement might not be as economical as to do away with the condenser altogether when the building has to be heated. Few condensers actually increase the power more than 25 per cent., counting in the cost of running them, while if the same space is to be heated by a direct steam return system it will require the burning of nearly as much coal as is needed to run the engine, or at least 90 per cent. additional. Hence it appears to be more economical to do away with the condenser in cold weather. When one reflects that in many shops the exhaust steam is totally wasted he can not wonder that manufacturers continue to cut down the wages of their employees more and more as the cost of fuel increases; but the economy of employing cheap men is and must always remain very doubtful, and there are few engine plants today, in charge of ordinary engineers, that would not be rendered from 10 per cent. to 50 per cent. more productive by the employment of a first-class man.

TRADE PUBLICATIONS.

STEAM HOT-BLAST DRYING AND HEATING APPARATUS.

A NEW illustrated catalogue showing some of the latest designs of hot-blast apparatus for drying lumber and heating buildings has been sent out by B. F. Sturtevant, of Boston, Mass.

The published engravings and data will undoubtedly prove interesting to all heating and ventilating engineers, and to those contemplating the erection of apparatus of that class. Sturtevant blowers and engines and complete plants are shown, and are accompanied by tables of sizes, capacities, etc.

THE J. L. MOTT IRON WORKS.

WE have received from the J. L. Mott Iron Works, New York and Chicago, circulars supplemental to their plumbing catalogue, illustrating Imperial Porcelain sinks; also their patent all Porcelain Bidets.

THE MASON REGULATOR COMPANY.

A POSTAGE stamp case is issued by the Mason Regulator Company, 22 Central Street, Boston, and it will be sent on request on receipt of a postage stamp. Stamps may be carried in the case in the pocketbook in the hottest weather without sticking.

THE NATIONAL HOT-WATER HEATER COMPANY

A TERRESTRIAL globe is issued by the National Hot-Water Heater Company, 191 Fort Hill Square, Boston, and also of Chicago. The globe is useful, and the idea seems to be that the company's customers get the earth in getting the Spence Heater.

THE BUILDERS IRON FOUNDRY.

WE have received from the Builders Iron Foundry, of Providence, R. I., their 1890 catalogue and price list, illustrating and describing the globe special castings and fittings for water-works, with a revised price list.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ARCHITECTURAL COMPETITIONS

Greenville, Miss.—Jail.—Plans are wanted until July 7, for a jail at this place. Address C. M. Johnson, Clerk Board of Supervisors, as above.

CONTRACTING INTELLIGENCE

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." *Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.*

Persons who make any use of the information they find in these columns we trust will not omit to mention The Engineering & Building Record as the source

For works for which proposals are requested see also the "Proposal Columns," pages i-ii-x 80.

WATER.

For Additional Water Items see Proposal Columns.

Union, S. C.—Reports say that this place is to have a system of water-works, and that the Mayor can furnish particulars.

Winston, N. C.—The Mayor can furnish important information regarding a projected water-wor s system for this place.

Warrior, Ala.—Reports say that this place is to have a system of water-works, and that the Pearson Coal, Iron and Railroad Company can furnish information.

Norma, Neb.—It is now proposed to issue bonds at once in the sum of $3,000, for the purpose of establishing a system of water-works.

Milwaukee, Wis.—Schedule of bids for constructing a water-works tunnel, 7½ feet in diameter, extending out 3,000 feet under Lake Michigan, for the city of Milwaukee, Wis. Bids for this work were opened June 20, but as the prices were too high the work was readvertised and opened June 30, as follows:

Bidders.	Furnishing and putting in place the crib complete.	Shore tunnel per lineal foot including distributing wells with connections, and the gate well copings and covers. 260 lineal feet.	Shore shaft complete per lineal foot with coping and cover and all connections complete. 153½ lineal feet	Lake shaft, complete, per lineal foot, including iron cylinders with all connections. 140 lineal feet.	Lake tunnel, per lineal foot, and extensions on opposite sides of each shaft. 3,157 lineal feet.	Rock excavation, per cubic yard. 120 cubic yards.	Section No. 1, of the intake complete (not including crib), in the aggregate.
C. H. Starke	$38,000.00						
John J. Crilley		$20.00	$400.00	$431.00	$20.00	$7.00	$191,200.00
John O'Neil	34,000.00	28.00	80.00	172.00	28.00	7.00	132,876.00
Thomas R. Bentley and Wenzel Strachota		42.50	85.00	170.00	29.40	10.00	141,089.00
William Forrestal	34,500.00	30.00	100.00	125.00	27.50	10.00	128,667.50
Shailer & Schniglau	40,000.00	30.00	55.00	145.00	26.50	12.00	121,643.00

The contract for the crib was awarded to John O'Neil, and for the rest of the work to Shailer & Schniglau.

Central, Ill.—A proposition to put in water-works on the franchise plan has been made by H. Hungerford, of New York. He proposes to lay six miles of mains, and furnish sixty hydrants for a rental of $3,000 yearly.

Gananoque, Ont.—There is talk of building an improved system of water-works at this place, the estimated cost of which is $43,000.

Spring City, Tenn.—W. W. Stephenson, Secretary of the Anglo American Association, writes: "We have not yet made definite arrangements for the construction of water-works. As soon as we are ready to let out the contracts we will let you know."

Hunter, N. Y.—Village Clerk A. E. Green writes as follows: "An application of certain parties in this place to form a water-works company has been granted. Work to be completed before July 1, 1891. For further information, address William J. Rusk, President of Water-Works Company."

Bridgeport, W. Va.—Regarding the published report that this place was to have water-works A. D. Fitzhugh, the Recorder, writes: "There are no water-works contemplated in our town; we have but 400 inhabitants and not likely to have water-works soon."

Parkersburg, W. Va.—Mayor G. Z. Gibleing writes: "No definite action has as yet been taken by the Council on the subject of extending the water-works plant, but I have recommended that they put in an extra set of boilers—viz., two tubulars, 16 feet long and 60 inches in diameter. The committee will probably agree, after which the Council will take some definite action in the matter."

Blaine, Wash.—Town Clerk J. W. Sauner writes; "A franchise has been granted to J. V. Chown and J. M. Weistling, of Seattle, Wash., to put in a system of water-works to be in operation by January 1, 1891."

Hamilton, Can.—A new 6-inch water main is to be laid here. For particulars address M. A. Pigott, as above.

Toronto, Can.—A scarcity of water prevails in this city, and the question of increasing the supply is being discussed.

Griffin, Ga.—Reports say that work on the projected water-works system for this place will begin inside of 90 days.

Los Angeles, Cal.—Urgent measures are being taken in this city towards providing a system of water works. A committee, with Dr. H. Linsabaug at its head has been appointed to investigate the matter.

Malden, Mass.—S. M. Allis, Superintendent Water-Works, is now getting prices for 400 tons of water-pipe, mostly 10 and 12 inches, for replacing old pipe and extensions.

Frankfort, Mich.—The Michigan Pipe Company, of Bay City, Mich., have the contract for the entire system of water-works for Frankfort. The work calls for work pump house, two sets of duplex pumps, one reservoir, about 20,000 feet of pipe of assorted sizes, 34 hydrants and 21 valves, etc. The work is to be finished before December 1, next.

Phillipsburgh, Kan.—City Clerk Frank R. Stinson writes: "We have voted $20,000 bonds and will immediately put in that sized plant. Bids have been advertised for, for bonds and for the construction of plant in full or in part. All bids, if a sufficient number are received in time, will be opened on July 2. S. K. Felton, of Belleville, Kan., is our engineer."

Water-Works.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Fargo, Dak.; Sioux City, Iowa; Newark, N. J.; St. Louis, Mo.; Imlay City, Mich.; Hicksville, O.; The Dales, Ore.; Marion, O.; Dayton, O.; Athens, Ga.; Fremont, O.; Watkins, N. Y.; Washington, D. C.; Key West, Fla.; Para, Brazil; Coshocton, O.

Grand Rapids, Mich.—The Cook Well Company, of St. Louis, Mo., has made a proposition to the Board of Public Works of this city to introduce an improved system of water supply. The matter is now in the hands of the Committee on Ways and Means.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

Highland, Ala.—The city will, it is reported, petition the Legislature to authorize the issuance of $50,000 of bonds for a sewerage system at South Highland.

Winston, N. C.—It is now probable that the projected sewerage system will be established at this place.

Green Bay, Wis.—The project for establishing a system of sewers is still being discussed here. For particulars, address Mayor Elmore, as above.

Avondale, O.—Arthur S. Hobby, C. E., has completed plans for the construction of a system of sewerage for this town.

Geneseo, N. Y.—The following bids for the construction of sewers were received by W. A. Wadsworth, President Board of Sewer Commissioners, June 27: Barlow & Martin, Seneca Falls, N. Y., $12,881; John W. Vickers, Geneseo, N. Y., $15,545.25; Green & McGregor, Buffalo, N. Y., $15,977.50; Thomas F. Moore, Buffalo, N. Y., $16,475.50; Murray & Kennon, Elmira, N. Y., $17,996.50; Sullivan & Co., Utica, N. Y., $18,405; R. Y. McConnell & Son, Rochester, N. Y., $19,042.80; Bennett & Doll, Utica, N. Y., $19,902.50; Willard & Neff, Geneseo, N. Y., $19,943; Aug. Gisel, Buffalo, N. Y., $20,014.50; Brummelkamp & Conron, Syracuse, N. Y., $20,171; Bauer, Bruff & Albright, Rochester, N. Y., $21,104; N. L. Brayer, Rochester, N. Y., $21,131.50; A. H. Coons, Kingston, Pa., $22,102.50; Bovier & Beondsly, Elmira, N. Y., $23,629.

Uhrichsville, O.—This city has adopted plans for a complete system of sewerage and will soon advertise for bids on same. For particulars address E. J. Moore, City Clerk.

Jersey City, N. J.—Numerous sewer extensions are to be constructed here.

Pittsburg, Pa.—Additional sewers will be constructed here.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

Harper's Ferry, Va.—The Secretary of State has chartered the London Bridge Company, for the purpose of building a bridge over the Shenandoah, at this place.

Nebraska City, Neb.—A special election will be held July 8, to vote on the proposition to issue $100,000 in bonds for a wagon bridge across the Missouri River.

Sioux City, Iowa.—Reports say that the State Railroad Commissioners have ordered the building of a viaduct, to be 180 feet long, 60 feet wide, with approaches on either side of 450 feet.

Llano, Tex.—It is proposed to erect a bridge over the Llano River. The Mayor can furnish particulars.

Knoxville, Tenn.—The plans are now ready for the Fifth Avenue bridge, which is to be erected at a cost of $14,675.

Clinton, Iowa.—The Clinton and Illinois Bridge Company are preparing plans and will soon advertise for proposals for the erection of a high wagon bridge over the Mississippi River at this place.

Niles, Mich.—The Michigan Central Railroad Company will build a large wagon bridge crossing their tracks at this place.

Triangle, N. Y.—Appropriations have been made by the local officials for the repair of 12 bridges recently damaged by the floods.

Paterson, N. J.—The Passaic County Board of Freeholders met July 1 and voted to build three new iron bridges across the Passaic—one at Little Falls, one at Fifth Avenue, Patterson, and one at Thirty-third Street. The consent of the Bergen County Freeholders will be necessary to the erection of the last two.

Zanesville, O.—Press dispatches say that several bridges have been swept away in this vicinity by the recent storms, and steps will soon be taken to replace them.

Albany, N. Y.—The following bids for constructing a lift bridge over the Erie Canal were received by Edward Hannan, Superintendent of Public Works, July 1: On superstructure, W. H. Shepard & Sons, Havana, $10,190; Groton Bridge Manufacturing Company, Groton, $12,820. On substructure, Weider & McMahon, Rochester, $3,226.50; George Chambers, Rochester, $2,703; James Robinson, Rochester, $3,347.50. The contracts were awarded to the lowest bidder.

Bridges.—See our Proposal Columns for information regarding bridge construction at the following places: Foreman, N. D.; Mitchell, Dak.; Pembina, N. D.; Ritchie, W. Va.; Eureka, Cal.; Alder Point, Cal.; Shannel Co., Kan.; Evansville, Ind.; Albany, N. Y.

STREET-WORK AND PAVING.

New Brunswick, N. J.—See our Proposal Columns for particulars of work to be done here.

Akron, O.—Considerable street paving is to be done at this place.

Jersey City, N. J.—Considerable street paving is to be done here.

New York City.—The contract for repaving Broadway from the Battery to Thirty-second Street has been awarded to Matthew Baird. The gross sum for the work is $252,000.

GAS AND ELECTRIC-LIGHTING.

Warehouse Point, Conn.—An electric light plant is projected for this place.

York, Pa.—An ordinance is being prepared for letting out the contract for public lighting. Address the Mayor for particulars.

San Francisco, Cal.—The city clerk has been directed to advertise for bids for lighting the streets for two years.

Brooklyn, N. Y.—The Kings County Electric Light and Power Company has been incorporated in this city with James T. Lewis as one of the trustees. Its operations are to be carried on in the city of Brooklyn and on Long Island generally. The company proposes to manufacture, buy, vend, lease and operate apparatus and machinery for the generation of electricity and manufacturing, supplying, vending and leasing electric light, heat and power. The capital stock is $300,000.

Verona, Pa.—An electric light company has been incorporated at this place.

Phillipsburgh, Mont.—This place is to have an electric light plant.

Marysville, Kan.—The electric light plant at this place is to undergo alterations.

Ballston Spa, N. Y.—The local electric light company will increase the capacity of the plant.

Ottawa, Ill.—The Councils of this place are considering the bids of several companies, with the view of purchasing a municipal plant to cost about $20,000.

Alameda, Cal.—This place is to have electric lights.

Ogden, Utah.—The Citizens Electrical Light Company has been incorporated here with a capital stock of $30,000. Messrs. H. W. Smith, F. C. Priestly and others, are incorporators.

Randolph, Mass.—The streets of this place are to be lighted by electricity.

Petersburg, Ill.—An electric lighting company is to be incorporated.

Electric Railways.—New electric railways will be established and improvements will be made to those already built at the following places: Amsterdam, N. Y.

GOVERNMENT WORK.

Philadelphia, Pa.—Vault doors for cashier's vault, United States Mint; Opened June 28. Bidders: Hall Safe and Lock Company, $745; Farrell & Son, $470.

WASHINGTON, D. C.—The following proposals for the work specified were opened on the given dates by the Supervising Architect of the Treasury Department:

Texarkana, Ark.—Erection and completion of the United States Court House and Post Office; work does not include heating and approaches. Bidders: McCarthy & Baldwin, Washington, D. C., $102,756; Robert M. Jack, Wichita, Kan., $86,000; L. L. Leach & Sons, Chicago, Ill., $113,485; James M. Brown, Camden, Ark., $87,500; Anderson Bros., St. Louis, Mo., $120,000; James H. Coster, Baltimore, Md., $91,351.

BIRMINGHAM, ALA.—Iron floor, ceiling and roof construction for brick and terra cotta arches, etc., for United States Court House and Post Office; opened June 27. Bidders: Pennsylvania Construction Company, Pittsburg, Pa., $50,659; Fred. J. Myers Manufacturing Company, Covington, Ky., $45,450; McHose & Lyon Company, Dayton, O., $53,725; McCarthy & Baldwin, Washington, D. C., $48,725.

WASHINGTON, D. C.—Bids were opened by the Lighthouse Board July 2, for the erection on Outer Diamond Shoal, off Cape Hatteras, N. C., of a lighthouse. Each bidder submitted his own plans for doing the work, and the contract will not be let until the Lighthouse Board has studied these plans and decided which is the best. The bids received were as follows: Theodore Cooper & Co., New York, $474,000, the lighthouse to be completed by January 1, 1893; Anderson & Barr, Jersey City, $485,000, to be completed January 1, 1892; William Sooy Smith, Chicago, $488,325, to be completed within three years from date of contract, and James Andrews, Allegheny City, and Gustav Lindenthal, Pittsburg, joint bid, $1,820,300, to be completed within two years from date of contract.

INDUSTRIAL.

XENIA, O.—John A. North, of this city, has the contract, at $3,000, to reconstruct the plumbing at the Ohio Soldiers' and Sailors' Orphan Home.

ST. PAUL, MINN.—A steam regulating plant, to cost about $9,000: for the court house and city hall is being discussed.

CHICAGO, ILL.—The Wells Glass Company, of Chicago, have been awarded the contract for furnishing the stained and pyrographic glass for Hermann's new Brooklyn Theater, and for the Gaiety Theater, New York.

CHICAGO, ILL.—The Lincoln Iron Works and the Jackson Architectural Iron Works, of New York, have established an extensive branch at 369 Wabash Avenue, Chicago, under the management of Messrs, M. E. Butler & Co.

PROPOSALS.

(Continued from page x.)

SEWERS, Athens, Ga.—Proposals are wanted until July 20, for building 4,000 feet of separate system sewer; Address R. L. Bloomfield, Sewer Commissioner, as above.

SEWERS, Marion, O.—Proposals are wanted until July 18, for constructing about 17,300 feet of 18-inch outfall sewer. Address H. S. Jones, City Engineer, as above.

PIER, New York City.—Proposals are wanted until July 9, for building a new wooden pier, with appurtenances, including sewer boxes and a dumping board, at the foot of East One Hundred and Tenth Street, Harlem River. Address the Department of Docks, Pier A, North River, as above.

BRIDGE, Ritchie, W. Va.—Proposals are wanted until July 12, for the construction of a steel road bridge over Hughes River. Address the County Clerk of Ritchie County, as above.

SEWERAGE SYSTEM, Para, Brazil.—Proposals are wanted until September 16, for the construction of a system of sewers here. Address Justs Leite Chermont, as above.

WATER-WORKS, Ashland, Ky.—Proposals are wanted, no date specified, for the construction of a system of water-works Address the Ashland Water Supply Company, as above.

ROAD WORK, Dunkirk, N. Y.—Proposals are wanted until July 8, for doing certain road work here. Address Edward Madigan, City Clerk, as above.

LIGHTING, Binghamton, N. Y. — Proposals are wanted until July 14, for lighting the streets, etc., of this city by electricity for one year. Address W. J. Flanigan, City Clerk, as above.

SEWERS, St. Louis, Mo.—Proposals are wanted until July 8, for the construction of certain sewers here. Address Emory S. Foster, Secretary Water Commissioners, as above.

WATER-WORKS, Hicksville, O.—Proposals are wanted until July 16, for the construction of a system of water-works at this place. Address J Cook, Consulting Engineer, Toledo, O.

PROPOSALS.

CITY OF NEW BRUNSWICK, N. J.

Notice to Contractors.

SEALED PROPOSALS WILL BE RECEIVED by the undersigned, Clerk of the Common Council of the City of New Brunswick, N. J., until 12 o'clock noon, WEDNESDAY, July 23, 1890, for laying a 12-inch **MACADAMIZED PAVEMENT** on Livingston Avenue, in said city, from George Street to Comstock Street (about 20,000 square yards of pavement). The work to be done under the authority of and in conformity with Chapter No. 148 of the Public Laws of the State of New Jersey, passed 1889.

All bids must be made upon the blank forms furnished by the City Surveyor, at whose office, No. 1 Paterson Block, the form of contract and specifications may be seen, and other necessary information as to excavation, etc., obtained.

The Common Council reserves the right to reject any or all bids.

H. B. COOK, City Clerk.

New Brunswick, N. J., July 3, 1980.

ARMORY, Poughkeepsie, N Y.—Proposals are wanted until July 16, for the erection of an armory at this place. Address Josiah Porter, Adjutant-General, Albany, N. Y.

PAVING, North Tonawonda, N. Y.—Proposals are wanted until July 14, for doing certain paving at this place. Address T. F. Warner, Village Clerk, as above.

WATER-WORKS, Imlay City, Mich.—Proposals are wanted until July 11, for the construction of a system of water-works Address Charles P. Marshall, as above.

SEWERS, Fremont, O.—Proposals are wanted until July 22, for the construction of certain sewers. Address the City Clerk, as above.

GRAVEL ROADS, Corinth, Miss.—Proposals are wanted until July 14, for building a gravel road here. Address J. A. Scully, as above.

PRISON, Ellisville, Miss.—Proposals are wanted until July 8, for the erection of a prison here. Address E. B. Sharp, City Clerk, as above.

PAVING AND SEWERS, Buffalo, N. Y.—Proposals are wanted until July 7, for paving certain streets and constructing certain sewers. Address George E. Mann, engineer, as above.

LIGHTING, Los Angeles, Cal. — Proposals are wanted until July 14, for constructing and maintaining an electric light plant for a period of two years. Address the City Clerk, as above.

WATER-WORKS, Watkins, N. Y.—Proposals are wanted until July 23, for the construction of a system of water-works at this place Address Daniel Beach, of the Board of Water Commissioners, as above.

SEWERS, Newark, N. J.—Proposals are wanted until July 8, for the construction of certain sewers. Address John Hunkele, Street Commissioner, as above.

SEWERS, Dayton, O.—Sealed proposals will be received at City Auditor's office until July 18, for constructing about 2,000 feet of pipe sewer according to plans on file at City Engineer's office.

WATER MAINS, Sioux City, Iowa.—Proposals are wanted until July 8, for furnishing, laying, etc., certain water mains. Address L. H. Drumm, No. 1411 Geneva Street, as above.

TUNNEL, Pittsburg, Pa.—Proposals are wanted until July 8, for doing certain tunnel work. Address M. J. Becker, Chief Engineer, P. C. & St. L. Ry., as above.

WATER-WORKS, The Dalles, Ore.—Proposals are wanted until July 17, for the construction of a system of water-works at this place. Address Mayor M. A. Moody, as above.

BRIDGES, Shawnee County, Kans.—Proposals are wanted until July 17, for the construction of numerous bridges. Address J. M. Brown, County Clerk, as above.

SEWERS, Providence, R. I.—Proposals are wanted until July 10, for the construction of certain sewers Address John A. Coleman, Commissioner, as above.

THE Editor of THE ENGINEERING AND BUILDING RECORD is always glad to receive items of news for the Contracting News Department. But such items are not considered news except when the prices and particulars of the award of a contract are given. The announcement that ——— has sold ——— to ——— without giving the *prices* and particulars concerns only the buyer and seller. Such notices are always excluded, except in the case where a certain firm is stated to have taken a certain contract, the execution of which would require that they should buy certain materials. Such an item would be used if deemed of more than local interest, because it would suggest to some readers the possibility of their making a sale or securing a sub-contract.

Building Intelligence.

We solicit from each and every one of our readers information relating to projected buildings in their locality, and should be glad to receive newspaper clippings and other items of interest.

CANTON, O.—Nothing over $7,000 in value to report.

DENNISON, O.—Nothing over $7,000 in value to report.

DAYTON, O.—Nothing over $7,000 in value to report.

HARRISBURG, PA.—Nothing over $7,000 in value to report.

LITTLE ROCK, ARK.—Nothing to report of $7,000 or over.

LEBANON, MO.—Plans have been prepared for the erection of a $65,000 hotel at this place. Address Architect L C Miller, Laclede Building, St Louis, Mo.

MADISON, WIS.—Nothing over $7,000 in value to report.

OIL CITY, PA.—Nothing over $7,000 in value to report.

POUGHKEEPSIE.—Nothing over $7,000 in value to report.

ROCHESTER, N. Y.—Nothing over $7,000 in value to report.

ST. LOUIS, MO.— N w cor Page and Prairie avs, br dwell; cost, $7,500; o, A & C Meglitsch; b, A Meglitsch.

S w cor Maple and Lindell avs, fr church; cost, $8,200; o, West Pres Church; b, J Coultas.

Leffingwell av and Walnut st, br dwell; cost, $15,000; o and b, Kiel & Danes Cont Co.

Washington and Newstead avs, 3 br dwells; total cost, $21,000; o and b, Costano & Martin

SAN LUIS POTOSI, MEXICO.—2 market houses; cost, $200,000; o, City; a, Alfred Giles; b, Alfred Giles & Co.

SIOUX CITY, IOWA.—Pierce st, cor of 13th st, 2 dwells; cost, $8,000; o, E E Selsmer; a, J W Martin; b, not let.

Pierce st, cor 13th st, block of br dwells; cost, $20,000; o and b, F F Beck; a, same as above.

SPRINGFIELD, MASS.—Maple st, granite retaining wall; cost, $35,000; o, D B Wesson; a, B H Seabury; b, Flynn Building and Construction Co, of Palmer.

Maple st, br stable, granite trimmings, fireproof construction; cost, $30,000; o and a, as above; b, Patrick Beston.

ST. PAUL, MINN.—Victoria, nr Laurel, 2-story fr dwell; cost, $8,000; o, L A Schak.

TACOMA, WASH.—The plans of Proctor & Dennis, architects, have been accepted for the $300,000 court house at this place.

TIFFIN, O.—A factory building will be erected here, at a cost of $20,000. Address A C Baldwin, as above.

TYLER, TEX.—Architect J H Bothwell has prepared plans for the erection of a $25,000 building at this place.

WALTHAM, MASS.—Lexington nr Main st, br court house and police station; cost, $27,000; o, City of Waltham; a, Hartwell & Richardson; contract not let.

WORCESTER, MASS.—Nothing over $7,000 to report.

WILCOX, NEB.—An opera house will be erected here at a cost of $15,000. Address Wilcox, Parker & Bradford.

YORK, PA.—South George st, br Sunday school bldg, with gallery to seat 1,200; cost, $12,000; o, Christ's Ev Lutheran Church; a, J A Dempwolf; b, contract not yet let.

WILKES BARRE, PA.—No Franklin, 2 semi-detached br and stone dwells; cost, $10,000; o, est B G Carpenter; a, Nipp & Podmore; b, P R Raife.

THE ENGINEERING & BUILDING RECORD
AND
THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22. NUMBER 6. PUBLISHED EVERY SATURDAY. 277 PEARL ST., NEW YORK.

NEW YORK, JULY 12, 1890.
LONDON, JULY 26, 1890.

SINGLE COPIES, TEN CENTS. Subscription, $4.00 per year in advance, post paid. IN AMERICA
SINGLE COPIES SIXPENCE. Subscription, 20*s*. per annum in advance, post paid. IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.
20*s*. in GREAT BRITAIN. Other Foreign Countries $5.
Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & CO., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $5; China, Japan, Sandwich Islands, Mexico and Cuba, $5; South America, $5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

LET THE SEWER SYSTEM FIT THE CITY.

A CORRESPONDENT calls our attention to an article in a contemporary laudatory of a system of sewerage which, as applied to a large Western city, had no main larger than 20 inches, while the house connections were but 4 inches in diameter, and remarks: "Such publications as this is are being distributed all over the country to the detriment of the cities contemplating building sewers."

We have no doubt that municipal authorities are often seriously misled in this way, and believing that what has proved good for one locality must be equally good for all spend much money on work that any well-informed engineer could have readily told them was not at all adapted to their special requirements.

Such conduct is about as sensible as taking another man's medicine because it cured him without waiting to find out whether he had the same complaint.

The officials of cities contemplating sewerage cannot be too careful to secure competent, disinterested advice before commencing work, and should remember that the "separate" and "combined" systems, so called, each have special advantages adapting them for special conditions, and that even in the same city one system may be best for one part and one for another.

FOOLISHNESS IN MUNICIPAL AFFAIRS.

THE Board of Public Improvements of Cincinnati has taken an extraordinary and indefensible course in its treatment of an engineer whom it had invited to take charge of the city water-works machinery. After the partial disabling of the machinery by the flood last spring a board of expert engineers was appointed to examine and report in regard to it, one member of the board being J. J. de Kinder, of Philadelphia. Some time after the report was made the Board of Public Improvements, which has full control of the water-works, invited Mr. de Kinder to go to Cincinnati and take charge for 90 days and put the machinery in order. The invitation was accepted and Mr. de Kinder went to Cincinnati, but his way was full of difficulties from the start and matters soon took such a shape that he gave up the work and returned to Philadelphia. There were many controversies, mostly personal or political, but with them we have nothing to do. Suffice it to say that after Mr. de Kinder had abandoned the work and left the city the Board of Public Improvements adopted a resolution as follows:

"*Whereas*, J. J. de Kinder, hydraulic engineer and disciplinarian, was engaged by this Board, with his right-hand man, to take charge of the machinery and repairs of the Front Street pumping house for a period of ninety (90) days; and,

"*Whereas*, The said J. J. de Kinder arrived in this city on the 19th of June, and from that date to the time of his departure, Monday, the 30th, he devoted the greater part of his energy and ability in endeavoring to get this Board to permit him to contract with Robert Wetherill & Co. for new pump ends for the Wetherill engines for the sum of $34,000, without submitting plans or specifications, and with the request that such contract be closed without receiving bids from others, all of which is contrary to law; and,

"*Whereas*, Said de Kinder, failing to secure authority from this Board to make such contract, proceeded to devote a portion of his energy and ability in another direction, without complaint of any kind to this Board, from the time of his taking charge. He sent his assistant to Philadelphia on Saturday, June 28, and on the same day he appeared in his chief rôle as the great disciplinarian. He announced to the public through the press, prior to any notice to this Board, the stumbling block thrown in his way, and his inability to secure entire control of the Water-Works Department, which he was determined to have, so that his methods of discipline should govern the entire department in its purchases, etc.; and,

"*Whereas*, Said J. J. de Kinder, in filing paper to the same effect to this Board, having failed to receive the indorsement and recognition he felt his due, he retired gracefully to the bar of the Gibson House, and with kindred spirits he dwelt on the miraculous ability of his favorite subject—de Kinder. He then cancelled his engagement and took the train to Philadelphia in search of his right-hand man, from whom it is presumed he kept all knowledge of what his left was doing.

"Now, therefore, be it *resolved*, That the thanks of this Board be and are hereby tendered to Mr. de Kinder for the entertainment he has afforded us in his great rôle as disciplinarian, and for the relief he has given by his voluntary retirement."

All the members of the Board present voted for this except one, and he did not vote at all. It goes without saying that such a demonstration cannot possibly harm Mr. de Kinder, but it is hard to believe that men charged with the administration of affairs in a great city could possibly commit themselves to such an expression, let the facts be what they might. It is an astounding exhibition of bad temper and bad taste and mental weakness. It is said that "politics" are responsible for the present lamentable condition of things in the Cincinnati water-works, but politics rarely makes men give such a public exhibition of silliness.

WOOD PAVEMENTS IN THE CITY OF MEXICO.

SOME time since the City of Mexico introduced what was hoped would be an improvement on the old cobblestone pavement in several of its streets, laying a Trinidad asphalt pavement on some and a wood pavement on others. Now the papers of that city object strongly to the wood pavement.

It has long been the custom in that city to wet the pavement thoroughly every morning, which makes the wood blocks slippery; besides, as the ground water is within 18 inches or 2 feet of the surface, the houses in the poorer part of the city are entirely without water closets or sinks of any kind, so that the population utilizes the center of the streets in the gray of the morning and throw slops there through the rest of the day. These conditions under a tropical sun, notwithstanding the altitude of the city, call for a monolithic pavement, as the wood pavement has become more offensive than the pavement it replaced

It has been suggested as a partial remedy that until a tunnel draining the valley is completed allowing of better sanitary arrangements, there be used disinfectants like sulphate of iron, and sanding the pavement when it is too slippery. Even in a temperate climate disinfectants could be used with advantage during the summer on wood pavements, and this practice would be a good one on Fifth Avenue, New York City, where the coal tar pitch has been worn out of the joints to a depth of over half an inch in many instances, so that shortly after sunrise on warm mornings a very fetid odor is given off from the animal and other refuse which has gathered in the cracks between the stones.

DEATH OF SIR EDWIN CHADWICK.

SIR EDWIN CHADWICK, K. C. B., died at Mortlake, near London, England, July 5, at the age of 90 years. He originated so much in regard to the healthfulness of human habitations and was so long a prominent figure in matters of the kind that he is often called the "Father of sanitary science," but still his work was primarily that of a philanthropist rather than of a man of science. He was not an engineer, and had professional education only for the law, but he saw the importance of what is now called sanitation, demonstrated the truth of his beliefs, and held them before the public with indefatigable persistence, and in the end exercised a great power.

Edwin Chadwick was born at Manchester, England, January 24, 1800. He studied law, entered as a student the Inner Temple in London, and became a barrister in 1830. While pursuing his studies, however, he supported himself by newspaper work, later he became a contributor to the reviews, and it was in this writing that his attention was turned to what became his life work. A statement made before a Parliamentary Committee in regard to the duration of life in the middle classes led Chadwick to investigate the subject, he finally wrote an article showing that the length of life had increased under the better conditions, and thereby touched the keynote of sanitary science, and that in a way to attract wide attention. Chadwick became associated with Jeremy Bentham, and assisted him in the great work on the administrative code of English law.

Chadwick's prospects in the legal profession were bright, but in 1832 a Government commission was created to examine the working of the poor law, Chadwick was offered a place as assistant commissioner, with the duty of making investigations from place to place, and, after some hesitation, accepted. He was from the first very active in the work of the commission, and in 1833 was made a chief commissioner. He was made a member of a Government factory commission the same year, and was active in urging much reform legislation. One of the first measures was the law prohibiting the employment of children in factories under a certain age, and the limiting the time of their work. Following this came an enactment called "the half-time system of education," which enabled factory operatives to have their children sent to primary schools. In 1838 Chadwick began the first movement looking to sanitary reform in London, the occasion being the breaking out of a fatal epidemic in the east end of the city adjoining some stagnant pools. He ordered an inquiry to be made as to the cause of the sickness, and the result was an exposure of existing evils as the cause of disease which led to the establishment of a sanitary commission whose duty it was to extend their inquiries throughout Great Britain. In 1848 Sir Edwin became the President of the first Board of Health. He had previously been honored by the title of Knight Commander of the Bath, by order of the Queen, for his exhaustive report on the sanitary condition of the laboring population of England presented to Parliament in 1842. The Board of Health broke up in 1854, and with it ended Chadwick's service in office. He repeatedly acted for the Government in regard to the health of the army, etc., in a semi-official way after that date. His last important public work was as President of the Association of Sanitary Inspectors.

Besides his work in the sanitary field Chadwick gave some attention to many political, economical and social subjects—taxation, civil service reform, temperance, education, etc.—and his writings were published in 1887 in two volumes, with the title of "The Health of Nations," the title being given by the editor, B. W. Richardson.

ACCORDING to John Richards experiments have shown that in rope transmissions more power is consumed in stripping the ropes from the grooves in the pulleys than was at first suspected. The incentive of a lower first cost led to making the angles more acute to secure traction, but the wear and loss of power increased accordingly. Modern practice tends to angles of 45 degrees and the pulleys should not be less than 30 times the diameter of the rope.

SMOKE ABATEMENT.

A correspondent of *Indian Engineering* suggests an original scheme for smoke abatement by asking whether it has ever been proposed to have a smoke duct running through a town connected up with the different furnaces. He suggests that such a duct might be carried outside of the city to a condensing station; an exhaust machine being employed to force the draught. At the condensing station the soot-laden air might be made to pass through water and thus deposit the solid matter, the air passing away comparatively pure, while the soot thus deposited might easily be collected, caked and sold as fuel. The size of the duct would have to vary, as in water and other mains, according to the work to be performed.

SOLID ORGANIC MATTER IN SURFACE WATER.

DR. DROWN, of the Massachusetts Institute of Technology, says that the amount of solid organic matter in a surface water which is fairly turbid with suspended plants is excessively minute. In the water of the Ludlow reservoir at Springfield, Mass., there is frequently an excessive growth of blue-green algæ, so that one would naturally suppose that the water contained a large amount of solid substance. But when this green mass is thoroughly dried the amount is less than one grain of solid, dry vegetable matter to the gallon. Whether, if taken in large quantities, it might have any appreciable effect has not been determined, but the dose is so minute, that even if it were a strong poison it would not do any particular harm.

TESTIMONIAL TO MAJOR MICHAELIS' FAMILY.

IT appears that Major O. E. Michaelis, of the United States Ordnance Corps, who died at Augusta, Me., in May, in consequence of injuries received in trying to save two of his children from drowning, left a family with almost no resources, and a move is made to raise a fund to assist them, to be invested in buying a house or otherwise. The widow has six children to provide for; she has taken steps toward assuming the burden and the fund was started without her knowledge. A circular, setting forth the facts in the case has been issued, signed by a number of engineers, to either of whom contributions can be sent, as follows:

William P. Shinn, 127 East Twenty-third Street, New York City; M. J. Becker, Chief Engineer P. C. and St. L. R. R., Pittsburg, Pa.; Charles B. Brush, 1 Newark Street, Hoboken, N. J.; F. Collingwood, Elizabeth, N. J.; John Bogart, 127 East Twenty-third Street, New York City; T. Comerford Martin, 150 Broadway, New York City; R. W. Pope, 12 West Thirty-first Street, New York City; S. S. Wheeler, 432 West Fourteenth Street, New York City, and George M. Phelps, 150 Broadway, New York City.

AMERICAN PUBLIC HEALTH ASSOCIATION MEETING.

THE Eighteenth Annual Meeting of the American Public Health Association will be held at Charleston, S. C., December 16, 17, 18 and 19, 1890. Topics for consideration are announced as follows:

1. Sanitary Construction in House Architecture.
    - (*a*) Heating.
    - (*b*) Lighting.
    - (*c*) Drainage.
    - (*d*) Ventilation.
2. Sewage Disposal.
3. Maritime Sanitation at Ports of Arrival.
4. The Prevention and Restriction of Tuberculosis.
5. Isolation Hospitals for Infectious and Contagious Diseases.
6. Establishments in Favorable Climates for persons having Tuberculous Predispositions.

Communications relating to local matters should be addressed to H. B. Horlbeck, M. D., chairman of the local committee of arrangements, Charleston, S. C. The address of the Secretary of the Association is Irving A. Watson, M. D., Concord, N. H.

JAPAN is making rapid progress in electric lighting. At present there are five companies having central stations, with a combined capacity of 22,300 lamps. Ten smaller companies, recently formed, are about to begin operations. They will supply 16,800 lamps.

NOTES.

THE Board of Health of New York City has formally declared the mains of the New York Steam Company in a down-town section of Broadway a nuisance, and ordered their use discontinued. This is the result of an inspection of a part of the company's street pipes.

A BOARD of the United States Engineers' Corps, consisting of Colonel W. P. Craighill, Colonel C. B. Comstock and Major C. W. Raymond, are at Philadelphia making an examination with regard to a new harbor line for the city in connection with the removal of the obstructing islands in the Delaware River.

A SCHEME is reported in St. Paul, Minn., for building an underground railroad from the Northern Pacific Railroad track through the alley between East Fifth and East Sixth Streets nine blocks to Broadway. The purpose is to deliver freight to wholesale stores along the route, and it is reported that Henry Villard and other influential railroad men are interested in the enterprise.

THE hydraulic valve described in the article entitled, "A New Method of Cleaning Reservoirs," in this journal, June 28, was designed by Capt. Edward Ruger, Chief Engineer of the American Water-Works Company.

A NEAT little pamphlet comes to hand with the title, which clearly indicates its contents, of "Recollections of General Grant; with an Account of the Presentation of the Portraits of Generals Grant, Sherman, and Sheridan at the U. S. Military Academy, West Point, by George W. Childs."

IT is reported that an electric railway company in Siam has been incorporated and that a road will be built at once from Bangkok to Paknam, a distance of 30 miles. This road is to cost $400,000, and Siamese capital will alone be used. An electric light company has also been organized and the plant ordered for Bangkok.

IT is announced that water will be temporarily turned on through the new Croton Aqueduct Tuesday next. The intention is to fill the Central Park Reservoirs and then shut the water off and complete some work about the Aqueduct.

OBITUARY.

WILLARD MARCY, President of the American Frost Meter Company, of Boston, died suddenly July 5.

PERSONAL.

J. A. STEWART was recently elected City Engineer of Cincinnati, O.

W. A. SOMERS has been appointed Engineer of the Water-works Department of St. Paul, Minn.

WILLIAM TAYLOR, Water-Works Superintendent of College Point, N. Y., has resigned his position.

JACOB J. RUECKERT, formerly with James W. McLaughlin, architect, of Cincinnati, has opened an office at the corner of Twelfth and Walnut Streets, of the above-named city.

GEORGE W. KITTREDGE has resigned his position as Engineer Maintenance of Way on the P. C. and St. L. Railroad to accept the position of Assistant Chief Engineer of the Big Four. F. T. Hatch will succeed Mr Kittredge.

CALVIN TOMPKINS, manufacturer and dealer in cement, stone, sand, etc., has just returned from Europe, where he has been investigating the methods of preparing and daily distributing ready mixed mortar from a central depot to buildings in construction throughout the city, and he is preparing to establish such a system in this city.

COL. JOHN MACLEOD, M. Am. Soc. C. E., has taken charge, as General Manager, of the construction of the Richmond, Nicholasville, Irvine and Beattyville Railroad from Versailles, 97 miles, to Beattyville, Ky. His office will be at Louisville, where he will continue his practice as consulting engineer. Colonel MacLeod is also building the New Albany Belt Railroad at New Albany, Ind.

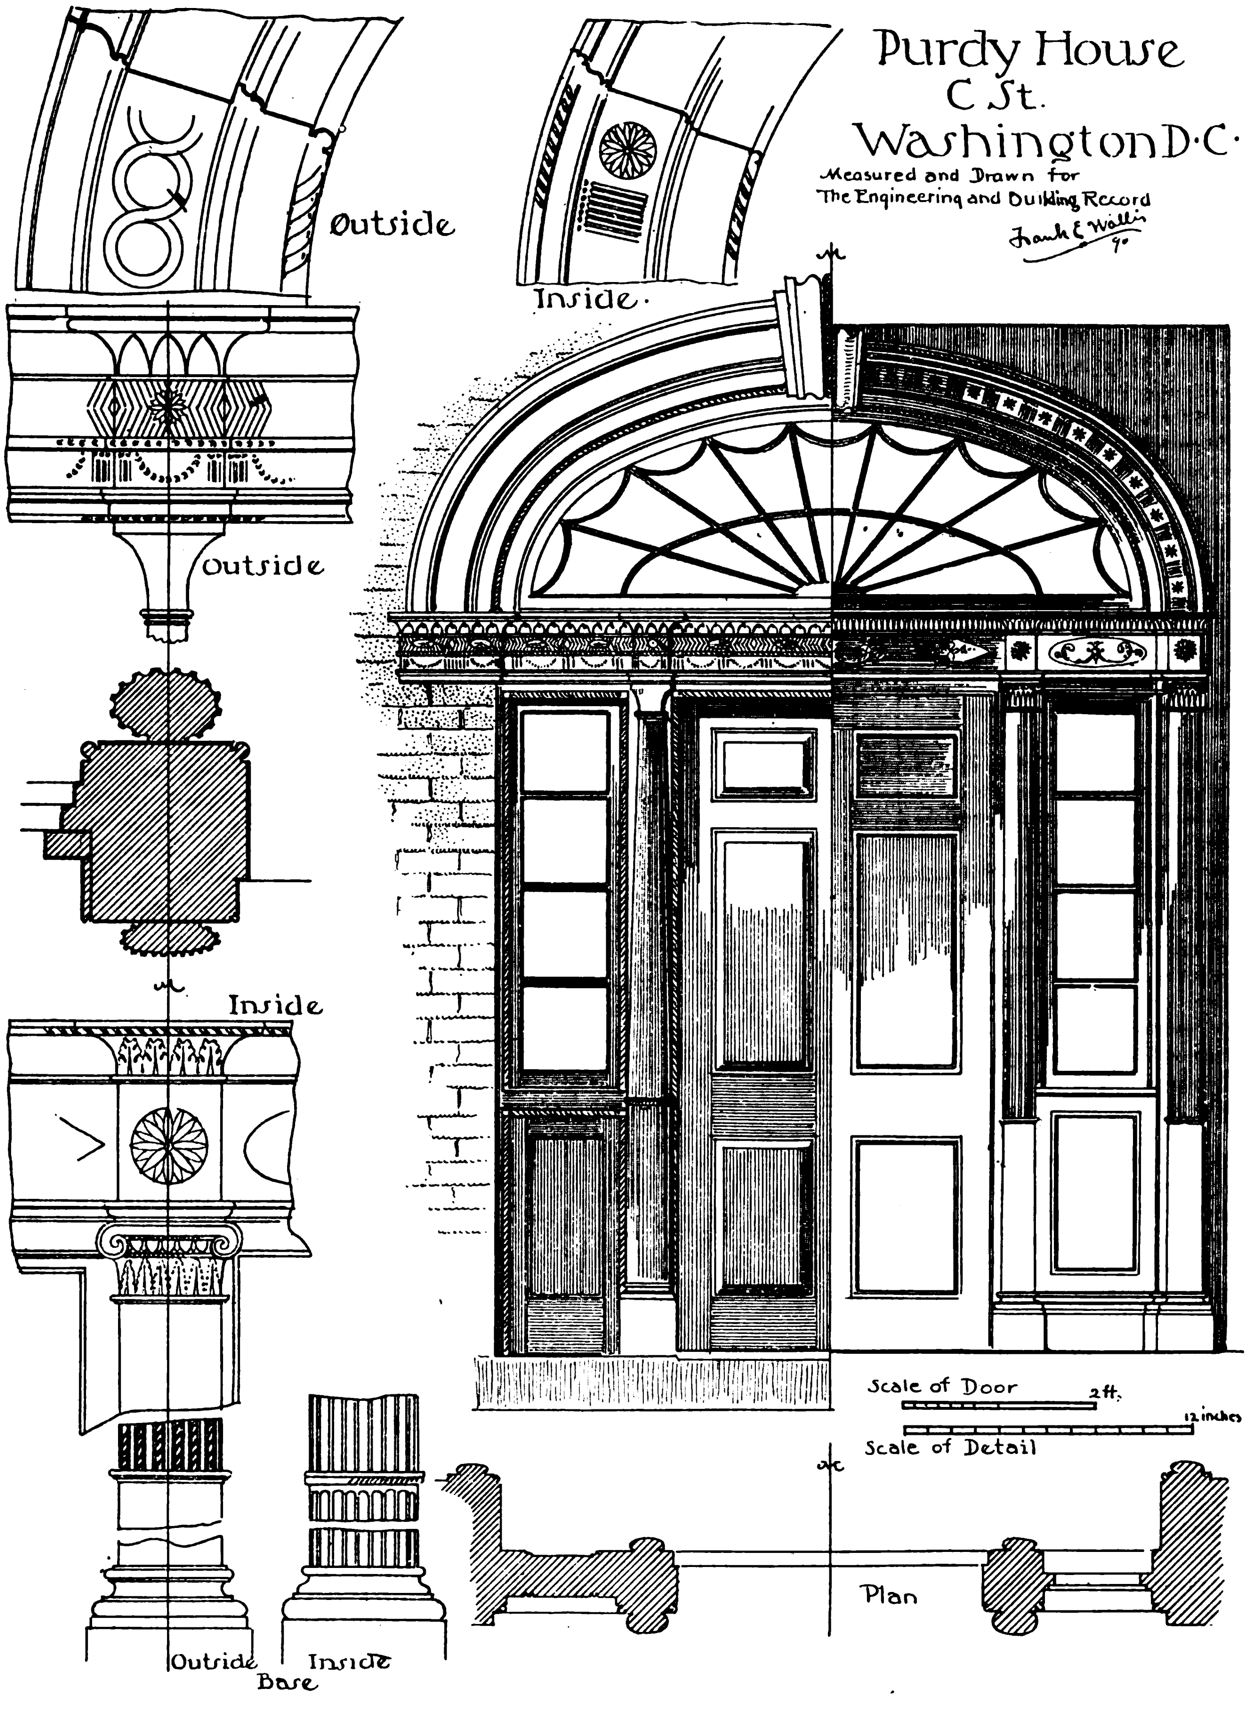
LETTER FROM ENGLAND.

LONDON, June 20, 1890.

THE Prince of Wales has exercised a wise discretion in expressing his opinion that an international exhibition should not be held in London before 1899 or 1900. This opinion has been criticised, but perhaps the best argument which can be advanced in its support is the fact that some manufacturers are actually using, as a recommendation for their goods, the statement that they have not been exhibited in certain exhibitions. The reason for such a statement is undoubtedly the very indiscriminate distribution of medals and certificates. Indeed it was openly said in connection with more than one exhibition that these medals and certificates were not available to those who did not go the right way to work to get them, while, on the other hand, the man who could afford to pay for them held a very great advantage.

In view of the approaching holiday season the authorities at Eastbourne are attempting to offer additional inducements and security to visitors. They have, therefore, decided that certificates of the sanitary condition of the various houses shall be issued where called for, and have appointed an additional staff of sanitary inspectors. These certificates are, of course, intended to affect the dwelling houses which are let out in lodgings during the season, but the optional nature of the certificate will undoubtedly defeat the objects of the scheme. While lodging houses, strictly and properly so termed, are obliged to have certificates from the health authorities, those dwelling houses which are, equally with the others, public lodging houses during the season have no such compulsion. It is not likely that in the scramble and competition which obtains throughout the height of the season, when householders are able to get their own exorbitant prices for their lodgings, the visitors will take the trouble to find out as a general rule whether the landlord's health certificate has been properly visèd.

The business of Oswald Mordaunt & Co., of Southampton, has been turned into a limited liability company trading as the Southampton Naval Works, Ltd., with J. H. Biles, lately with J. & G. Thomson, Clydebank, as General Manager, and Mr. Gearing, formerly Superintending Engineer to the Inman Line as engineer. The Southampton company proposes to turn out vessels of all tonnage, and claims to have additional facilities for that purpose.



THE PROPOSED SEWERAGE OF PART OF TRENTON.

A SYSTEM of sewerage proposed for that part of Trenton, N. J., known as Chambersburg, and lying south of the city along the Delaware River, is the subject of a report made by Rudolph Hering, of New York City, November 22, 1889, and recently published by the city authorities.

In recommending the adoption of Mr. Hering's plans, the Sanitary Committee call attention to the fact that "the problem to be solved was one of considerable intricacy, as the surface is so nearly level that it was impossible to apply the separate system except to small portions," and add, "no estimate of the cost of construction is presented for the reason that our people are becoming familiar with the expense necessarily entailed in the procurement of good sewer work."

It would appear that Mr. Hering had in 1885 reported a plan for the older part of the city, and the present report is therefore much in the nature of a supplement to the previous one, and the removal of sewage, surface and subsoil water have been "considered in the same light" as before.

The main outfall from the city, 5 feet 9 inches in diamter, passes through this new district, whose sewage it also receives, discharging it into the Delaware River a short distance below, although it is intended that ultimately the outfall shall be further down the river.

The laterals are designed for sewage only, the surface water being carried in the gutters for two or three blocks before entering the sewers, which thereafter carry everything until the main interceptors are reached, which are below the other sewers and consequently catch all their flow under ordinary circumstances, but when the flow is swollen by a storm then the greater part of it leaps over the interceptor into the overflow beyond, by which it is discharged directly into the river or into a creek leading to it, thus relieving the main outfall. This arrangement appears to give most of the advantages of the "combined" system, with much of the economy of the "separate" one.

The soil is gravel, loam and clay, and therefore easy to excavate, which is fortunate as, owing to the flatness of the ground and other reasons, some of the main sewers are over 20 feet deep for several blocks.

Much stress is laid upon the importance of thorough and competent inspection on the proposed work, and attention is called to the fact that when a contractor takes work at a price hardly sufficient to pay for its execution, it is almost impossible to prevent the slighting of some of it, and the recommendation is made "in the interest of good work," that contracts be awarded only to competent parties, and at prices which will allow them to do first-class work.

The report concludes with an acknowledgment of the conscientious care which W. L. Anderson, Engineer in Charge, has given to the work already built, by which, in spite of serious obstruction from water and quicksand and the consciousness on the part of the contractor that he was losing money, a fair piece of work was secured, better than is often obtained under similar conditions.

Two large colored sheets accompany the report, which reflect much credit upon those who had charge of its publication. One is a map of Chambersburg on a scale of 400 feet to the inch, and the other contains a set of profiles of all the main sewers.

ENLARGING THE EAST BOSTON DRY DOCK.

THE old Simpson Dry Dock at East Boston, Mass., originally completed in the fall of 1863, is being entirely rebuilt. While its general model will be retained the principal improvement contemplated is an increase in length of 100 feet, which will make the total length nearly 500 feet. On top the dock is 82 feet wide, and at the bottom 48 feet, and it will take in vessels of 19 feet 6 inches draught. While new gates will be built in the same position as the old ones, that is at about 400 feet from the inner end, the entrance to the dock, when extended, will be closed by a wooden caisson or floating gate similar to that in use at the Charleston Navy Yard. When it is necessary to use only a part of the dock the inner gates may be shut, which will give an inclosed space of 400 feet in length as heretofore, while in the case of large vessels when the entire length of the dock will be required these inner gates may be left open, and the caisson at the outer end put in position and there sunk by being filled with water when the dock can be pumped out. For this purpose centrifugal pumps will be used, having a capacity of 45,000 gallons per minute, and so arranged as to draw off water from the dock at any height and keep it entirely dry without the use of any supplementary pumping apparatus.

It is expected that it will take two months longer to finish work, the estimated cost of which is about $200,000. When completed this will be the largest dry dock in New England. M. M. Tidd, of Boston, is the consulting engineer, and James F. Fifield the engineer in charge of the work.

WATER DELIVERY FROM SERVICE PIPE.

AT the recent Portland, Me., meeting of the New England Water-Works Association, Mr. Dexter Brackett presented the appended table showing the quantity of water delivered by service pipes of various sizes, under various pressures. The table was taken from the annual report for 1877 of the Rochester, N. Y., Water Department. The results are given in gallons per minute. The different column headings show the proportion of head of water (H) to the length of pipe (L).

TABLE OF QUANTITY OF WATER DELIVERED BY SERVICE PIPES OF VARIOUS SIZES, UNDER VARIOUS PRESSURES.

Diam. of Pipe. Inches.	$H = 10 L$.	$H = 9 L$.	$H = 8 L$.	$H = 7 L$.	$H = 6 L$.	$H = 5 L$.	$H = 4 L$.	$H = 3 L$.	$H = 2 L$.	$H = 1\frac{3}{4} L$.	$H = 1\frac{1}{2} L$	$H = 1\frac{1}{4} L$.	$H = L$.	$H = \frac{3}{4} L$.	$H = \frac{1}{2} L$.	$H = \frac{1}{3} L$.	$H = \frac{1}{4} L$.	$H = \frac{1}{5} L$.	$H = \frac{1}{6} L$.	$H = \frac{1}{7} L$.	$H = \frac{1}{8} L$.	$H = \frac{1}{9} L$.	$H = \frac{1}{10} L$.

CORNELL'S COURSE IN ARCHITECTURE.

A CIRCULAR of information as to its course in architecture is issued by Cornell University, describing the conditions of admission and study for the four years. The purposes are summarized in a note, as follows: "The study is intended to cover the whole ground of education in architecture—practical, scientific, historical and æsthetic—as thoroughly as is possible in a four years' course. On its completion the student is qualified to take an advanced position in an architect's office. If he wishes to continue his studies he can return to the university as a post-graduate and, after a year's work, duly laid out, completed and approved, may receive the second degree, Master of Science in Architecture."

WATER-HAMMER AND CEMENT-LINED PIPE.

IN discussing the effect of water-hammer on cement-lined pipes at a recent meeting of the New England Water-Works Association, George E. Winslow, Superintendent of the Waltham, Mass., Water-Works, directed attention to the importance of having relief valves on large-supply branches. Among other things he said:

"I have but one elevator in Waltham connected with our mains, and that is from a cement pipe. It is connected with a 2-inch pipe; it was put in by a Worcester firm, and they showed me the valve they were going to use, and I told them I should require a relief valve on the service pipe close to the valve the elevator was worked with. The man in charge of it wanted to know why, and I told him because they could shut the valve so quick that they could create a water-hammer that would burst our main. He thought it was foolish; but I said: 'Our pipes are cement-lined pipes, the iron is thin, and it hasn't got the strength of cast-iron pipe; if it had, perhaps it would not be necessary to take this precaution.' Well, they finally put it on, and we have had no trouble from it, for there is no water-hammer; if there is pressure enough so that we might get a water-hammer the water escapes through the relief valve.

"We also have a stand-pipe in Waltham for the Fitchburg Railroad, and Mr. Turner, the chief engineer of the road, wanted to connect with our mains and put on a slow moving gate; that is, a gate with a fine thread, so they would shut the valve slowly, so they couldn't produce any water hammer. He wanted to get rid of a tank which was an eyesore in front of the depot. I told him I was afraid that, with the men who generally work valves on a railroad, they would burst our pipe by increasing the pressure rapidly by a sudden closing of the valve. He said they wouldn't do it, and he said, furthermore, 'I will put on a good, careful man, and he will be responsible.' But I saw one of those careful men operate a valve in Worcester at the Union depot one day when I was up there to see what kind of an arrangement they had—to see what I could do for the Fitchburg Railroad. The express train came through there along about 20 minutes past three in the afternoon, and I knew they would water up, and so I went to the depot to see them do it. The water was turned on, and the fireman didn't pay attention to his business as closely as he ought, and the consequence was the tank got pretty near full before he noticed it. 'Shut it down, you will overflow in a minute; hurry up, hurry up!' And they did hurry up, and that valve was shut just about as quick as it could be shut. That was the careful man who was taking care of that valve. Now I made up my mind that would be the case in Waltham, so I told Mr. Turner that if he would put on a relief valve which would be large enough I should be happy to put in a service for him. He didn't like that idea; and he is a pretty set man any way, as well as myself, and the consequence was we went through that fall and winter without any stand-pipe. In the spring he came to me one day and he asked me when I was going to put in the service for him. Said I, 'Just as soon as you can conclude to put in a relief valve. As I understand it you want a 6-inch pipe taken off from the street main, run through a 4-inch meter, and then a 4-inch pipe to your stand-pipe?' 'Yes.' Said I, 'As soon as you will put that in, and put in a relief valve close to the valve which operates the stand-pipe, and that shall be a 3-inch valve, and not be set at over 10 pounds above the standing pressure, just so soon we will put it in for you.' Said he, 'I will put in anything you want.' And the consequence was he put it it, and we never have had any trouble."

SHOULD PILES BE SHARPENED?

IN pile driving, it is said in the University of Michigan *Technic* to be held by many experienced engineers, both on the Atlantic Coast and on the Mississippi, that for ordinary ground the pile should not be sharpened. They say that the pile if sharpened rarely has its point in the neutral axis, and that the blows of the hammer are not applied so that the action line of the force passes through the point, and hence a couple is introduced tending to strain and weaken the timber. If, on the other hand, the pile is left blunt, the consolidated earth forms a point which, changing with each blow, keeps itself continually in the line of force and hence the straining couple is not introduced. In ordinary practice, however, the pile is tapered somewhat at the lower end, although not sharpened to a point.

NEW ENGLAND WATER-WORKS ASSOCIATION SKETCHES.

No. XIII.

(Continued from page 230, Vol. XX.)

COAL CAR FOR WATER-WORKS USE.

AMONG the sketches contributed to the recent Portland meeting of the New England Water-Works Association in response to a request which had been sent out for diagrams of any tools or devices of practical water-works interest, was that shown in the annexed illustration, submitted by Rudolph Hering, of New York. The illustration explains itself, the special advantage of the car being that it admits of readily shoveling the coal directly from it into the furnace. The car shown is used at the Toronto Water-Works.

COST OF AN ELECTRIC RAILROAD PLANT.

IN discussing a paper on "Working of Railroads by Electricity," presented by W. E. Hall at the last meeting of the American Society of Mechanical Engineers, F. A. Scheffler, of the Westinghouse Company, Pittsburg, Pa., gave some points on the cost of installing an electric railroad plant.

The ordinary locomotive of to-day when running at the average rate of speed and hauling the average load, does work of not less than 300 horse-power. Supposing the station to be built to have a capacity, to each 30 miles of section, of not more than one locomotive, the capacity of the generating station would, according to Mr. Scheffler, necessarily have to be about 360 horse-power, as the best forms of motors at present have an efficiency of only about 80 and 85 per cent. It will require, therefore, for the generating station a 360 horse-power engine and sufficient boilers for operating the same. The cost of the station can be summed up about as follows:

One 360 horse-power engine	$10,000
Battery of 360 horse-power boiler	7,000
Station building	5,000
Steam connections, pumps, feed-water heaters, etc.	2 coo
Generating dynamo	12,000
Electrical station appliances, etc	1,000
Making a total of	$37,000

The foregoing station outfit will not permit of having an auxiliary plant of engine, dynamos and boilers, which ought really to be included in the outfit, so that in case the engine or dynamos or boilers should at any time become inoperative there would be another set of appliances to operate the railroad with. An auxiliary set of appliances would almost double the total cost of the station.

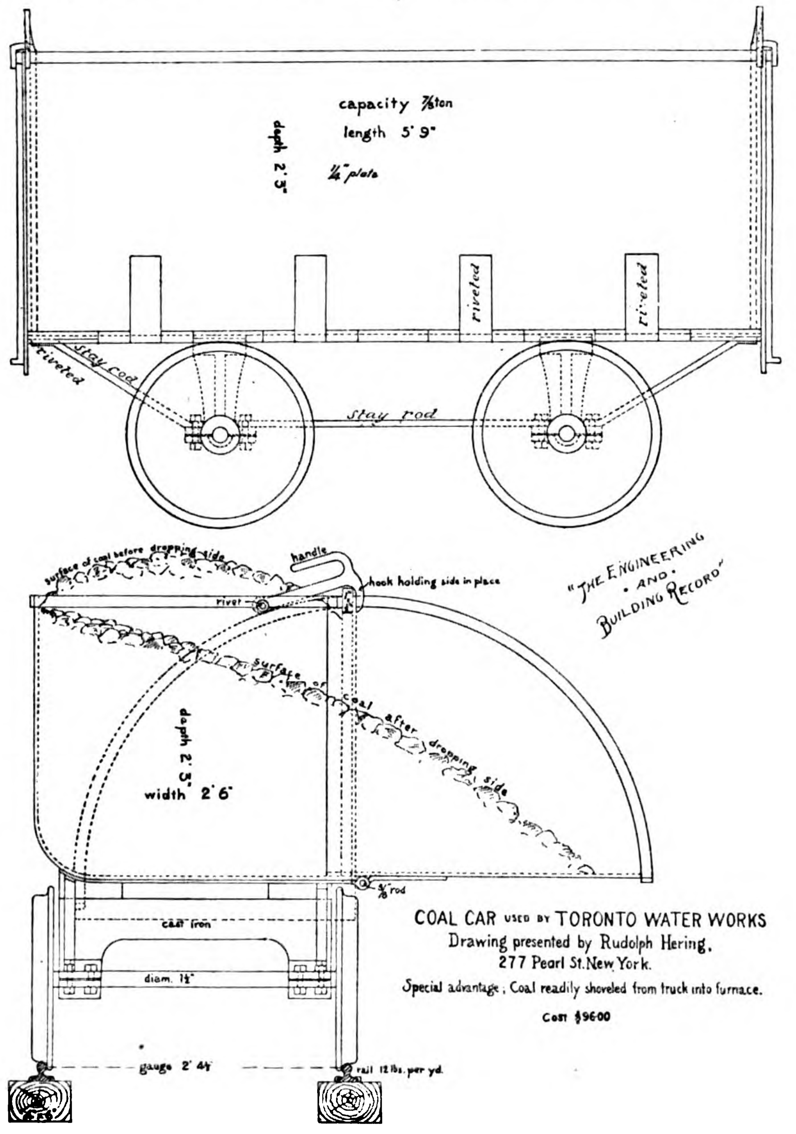
For operating expenses of the station we have the following:

5 per cent. depreciation on engine and boilers	$835
4 per cent. depreciation on dynamo	480
6 per cent. interest on station plant	2,220
Two firemen, night and day	1,440
Two engineers, night and day	2,000
Two laborers, night and day	1,080
Maintenance, such as oil, waste, etc	300
Making a total of	$8,355

per year, not including the cost of coal.

In order to ascertain what the cost of coal would be, we will suppose that the total power is required only for one-half the time, and one-quarter the power for the balance. This will give us 2,774 tons of coal per year required. This assumption is based on the supposition that the engine will require three pounds of coal per horse-power hour. If it was a condensing engine, of course the assumed rate of coal per horse-power would be too high, but the speaker should not think it advisable to use a condensing engine where the power would be so largely variable, and water along railroad plants is not always available for condensing purposes. Basing the cost of coal at $3 per net ton, the expense per year for same will be $8,322; adding this to the operating expenses of the plant at the station, we have a total of $16,677.

So far we have only taken into consideration the necessary cost of operating expenses of the station plant. We have now to consider the erection of the necessary electrical circuits along the line, the depreciation of same and the interest on the cost of same. Suppose that the pressure of the terminals was fixed at 2,000 volts, in order to deliver 300 horse-power to the motor it would be necessary to carry 112 amperes on the line, and allowing 20 per cent. drop in the pressure, by simple matter of calculation we find that the conductors will have to be of an area equal to a copper rod one inch in diameter. The pressure of 2,000 volts is altogether too high to think of using in a safe manner the rails for the return circuit, and a copper conductor would also have to be used for this circuit, making two lines of copper conductors one inch in diameter for the outgoing and return circuits. If the circuit is 30 miles long, it would require the enormous quantity of 476,784 pounds for each conductor, and the cost of copper wire at the present time being 17 cents per pound, the amount required to pay for the copper wire would be $162,106. The interest on this outlay at 6 per cent. would be $9,726. As an overhead circuit would be the cheapest possible way of conveying the current to the motor, and as the wire is of such an enormous weight, it would not be well to have the poles more than 50 feet apart. This would require 6,300 poles. Basing the cost of the poles and erecting same at $2.50 each, we have a total of $15,750. Erecting the line would be charged at $150 per mile, and this is a very low figure; this would give us $4,500, making a total cost of for the line of $20,250. The interest on this at 6 per cent. would be $1,215. Continuing the statement of operating expenses, it will be necessary to add the interest just given to same, and also the depreciation of the line. Putting this latter at about 2 per cent. (which is very low), which would be $3,627, we have a sum total of $31,245 as the actual total annual cost of operating expenses of the station plant, and interest, depreciation, etc., on each section of 30 miles.



COAL CAR USED BY TORONTO WATER WORKS
Drawing presented by Rudolph Hering,
277 Pearl St. New York.
Special advantage; Coal readily shoveled from truck into furnace.
Cost $96.00

It will not be necessary to take into consideration the cost of operating the motor, as this would be about the same as the cost of operating the steam locomotive, and the first cost of same would be about the cost of a first-class locomotive. The only comparison which should be made between the operating expenses of the steam locomotive and the electrical plant would be that of the difference of coal consumed between the station and the steam locomotive, and possibly the cost of repairs of the motor compared with that of the locomotive. The coal consumed by the ordinary locomotive is probably not less than eight pounds of coal per horse-power hour. This being the case, and the locomotive develops 300 horse-power for 12 hours, and one-quarter of this horse-power for the balance of the day, we would have per year a consumption of 6,570 tons. This, at $3 per ton, is equivalent to $18,710. Deducting the same from the cost of total operating expenses of the electrical station, we find that the difference is in favor of the steam locomotive to the extent of $12,475 per year. There would probably not be any difference in cost of repairs between the electrical and steam locomotive. The total cost of the station, copper wire and pole line complete would be $219,356. This amount of money would buy about 20 new locomotives.

The foregoing estimates are all based on inside figures, and if the railroad was 600 miles long it can be readily seen what an enormous expenditure for electrical purposes would be necessary, and comparing this with the cost of the present steam railroad, would be sufficient to upset any calculations in the line of electrical railroads.

A voltage of 2,000 has been taken as a basis for estimating the cost of the line, simply because it would require extraordinary care in insulation for a higher potential where the bare conductors, connections, insulating material, etc., would be subjected to all kinds of rough weather. If it were found that 4,000 volts could be satisfactorily insulated (and this has been done with covered wires in a few special cases), the first cost of line equipment would be very largely reduced to, say about one-half the above estimated cost, thereby reducing the yearly expense of operating by decreasing the interest and depreciation of the plant. As far as safety to human life is concerned, it is not likely that 4,000 would annihilate more completely than 2,000 would, but the chances for leakage of current at the higher voltage would be much greater. This would mean greater coal consumption and reduced efficiency of the electrical apparatus.

The operation of the plant at full power for one-half of the time involves, of course, the use of several motors, which has not been considered in the matter of operating expenses. Such consideration would not make any appreciable difference in cost of operating expenses, because there would necessarily be the same amount of expenses in the line of engineers, firemen and depreciation, etc., on the locomotives as there would be upon an equivalent number of motors.

It is safe to say that unless there are some radical changes made from the ordinary design of electric generators, and in the method of transmission of the current to the motor, as well as a motor of greater efficiency, that we will never see electric railroads operated in this or any other country.

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

(Continued from page 75.)

REPAIRING A CHURCH ROOF TRUSS.

The Warren Avenue Baptist Church in Boston, Mass., is a brick structure built in 1864. Figure 1 shows the general plan, with a tower at Z and entrance wings at Q Q.

Figure 2 is a cross-section showing the roof construction. S and S' are longitudinal trusses that support the "scissors" trusses O O, etc., over the main part, and the inner ends of the lean-to rafters P P, etc., over the side parts. U U, etc., are purlins and R R are 1-inch diagonal rods for wind bracing in the end panels of the roof only.

Figure 3 is an elevation of the longitudinal truss S, whose details are shown enlarged in Fig. 4, which also gives a section at Z Z. The angle blocks and plates W and V were each cut 3 inches into the chords across their entire width, and as the diagonal rods E cut out at least one of the boards which composed the chord the maximum loss of section was over 57 per cent. The trusses were entirely without vertical struts, and the top and bottom chords were only kept from approaching each other when strained by the resistance of the clere-story studding and boarding shown by vertical lines in Fig. 3.

T T, etc., are windows. When first erected the trusses S and S' were found too weak, and were each reinforced by four 1¾-inch rods F F, etc., with nut bearings on iron plates across the ends of the lower chords. The different sections of these rods were simply hooked into each other, and the hooks tied down with strap iron as shown in Fig. 4. The rods were sprung down to the bottom of the chord at the center, and held there by occasional staples driven into the wood.

The scissors trusses O O, etc., were double and their two parts were not fastened together, the cross pieces being put on with 5 by ⅜-inch spikes, three at a joint, that only pierced two pieces and did not connect the twin members.

The roof existed in this condition about ten years, when the longitudinal trusses S and S' were noticed to be spreading at the top, and the adjustable tie rods W (Fig. 2) were put in through their top chords at the foot of each cross truss O. About 12 years later it was accidentally noticed that the trusses S and S' were sprung and canted out of their vertical planes. The boarding was removed to expose them, and their bottom chords were found broken and the roof in the position indicated in Fig. 5, where the center lines of the trusses are shown by full lines for the proper position and by dotted lines for the position which they had assumed, drawn somewhat exaggerated for distinctness. The south truss S was in the worst condition, and, deflecting a certain amount D, had been pushed at the bottom 6 inches towards the center by the side rafters P, which acted as struts pivoted at Y where they were fixed to the wall.

The scissors trusses C C, not having enough rigidity in the spiked joints to resist the strain, became distorted, the top of the truss S carried 4½ inches outward, and by the rods W brought the top of the north truss S' with it. The deflection of S and S' was so great as to throw heavy strains on the rods R R (Fig. 1), and there was danger that they would break, and that the trusses S and S' would capsize and the roof and perhaps the walls fall.

It was decided to immediately reconstruct the trusses. Piers were built under the floor, and above it, on 8x12-inch blocking, a heavy working platform was made and extended to protect all the pews. The weight of the roof was then transferred by jack screws to the main and intermediate piers, and the trusses S S' were rebuilt

In Fig. 6, C C is the center line of the trusses. At the left, half of the south truss S, is shown as reconstructed, and at the right, half of the north truss S' is shown as it was reconstructed.

Figure 7 is a section at Z Z, Fig. 6.

Figure 8 is an elevation of the new connection details, with sections at Y Y and Z Z. The trusses O O, etc., are indicated in Fig. 6, but the rafters P P, etc., are omitted for clearness. In the truss S the top chord was so much twisted that it was turned flatwise, and seven of the eight 2x14-inch plank composing it were bolted to the new 8x8-inch reinforcing pieces M, which overreached it 2 inches, and in this space inclined pieces G were set under the lowest purlins.

In the truss S' the old top chord was not changed, except to add the 8x12-inch reinforcing piece L, and the 2x14-inch plank N to bolt to, and to cut into the face of the old chord to set the braces G.

All the old inclined posts were removed except those marked D D, etc., and were replaced by new ones H H, etc., 8x12 inches in pairs and set in lighter angle blocks, V, Fig. 8, with web pieces to secure the post instead of the 1-inch wooden pins, which, in the old posts, had in some cases been compressed to ⅝ inch in one direction.

The tops of the posts H H were mortised into the pieces L and M, and secured by iron side plates U and cross bolts. The vertical posts and ties I and J were added at every panel, and pieces K were notched on 2 inches at the center of every panel.

Both chords were thoroughly bolted throughout, the lower chord being secured by clamps B B, etc., and having additional hooks A A', etc., to secure the rods F F, etc. The pieces Z Z (Fig. 2) were also added to the trusses O, whose joints were secured by bolts shown by the small circles.

The weight of new castings was about 2,800 pounds less than that of the ones they replaced in each of the longitudinal trusses.

These repairs were estimated to cost $3,000 or $4,000, and were executed by J. Purdy French, of Boston. I. C. Blair, also of Boston, who discovered the distortion of the trusses, erected the staging and had general oversight of the repairs.

NOTES ON THE CARE OF SEWERS.*

Assuming first that the sewer or system of sewers has been well designed for the work it is to do, and properly located, the care given to the sewer or system should begin when the first brick or pipe is laid, and should continue so long as the sewer is in use. The average "city father" of the average city is not educated up to the point of believing that anything more is necessary to the procuring of a sewer than the employment of some one to build it. He thinks, in brief, that a sewer is an elongated hole in the ground, surrounded by brick or pipe, laid in some shape by somebody, and that any special oversight or skilled labor used in behalf of the city during construction is an unnecessary refinement of engineering, and any money spent afterwards for supervision or care of the work is so much additional and useless tax upon the citizens. Such is about the belief of the average city father, but I am happy to say that my lot has been usually cast among those of a better belief. We, as engineers, know that almost any man can lay pipes in the ground or pile up bricks and mortar; that it takes a skillful man and a mechanic to make a good sewer of the same materials.

The first great care of the engineer in building a sewer is to see that his alignment and grade are true, and the second is to see that the materials are of the best description and properly placed. In the matter of alignment and grade, it seems almost imperative that each pipe should be laid to a line in order to get the best results. It is the practice in some places to give a stake on the side of the proposed trench, from which to measure for both line and grade, and in other places the line is marked out in advance by stakes, and the grade afterwards given in the bottom of the trench. In still other places the approximate line is worked on the ground in advance, and the grade is given as about so much below the surface here, and about so much there, leaving the sewer builder to regulate affairs in between points as suits him best, regardless of results. Any method which will secure a straight and true line of sewer is a good one; the one of placing grade points on line and at an even number of feet above and parallel to the water line seems to be the best. From these points a line can be stretched, and from this line each length of pipe should be set by a plumb line and a measured pole or steel tape. In case of very large or deep sewers the details may be varied to suit the case in hand. The grade line having been established and the contractor ready to begin, the engineer (unless he has no other employment) will need a competent and reliable inspector to see that the sewer is actually laid as it should be, and to see that the materials are what have been agreed upon. And upon this same inspector rests a large part of the burden of securing an excellent piece of work. He must be ever present and ever watchful, or something may go wrong, and after lying buried for years, perhaps, that wrong spot will show itself in some way to bring discredit upon both engineer and inspector. He must see that each pipe is sound and true before it is lowered to the bottom. He must know that the pipe to follow will fit well to make a true and smooth water line, even if the two pipes are not exactly concentric. He must see that the cement is good and properly mixed. He must see that each pipe is laid to line and grade, the joint carefully made with cement all around the pipe, and not disturbed until it is well filled around and over. He must tell the pipe layer at least a hundred times a day to tamp well around the pipe and to wipe it out so as to remove loose cement or sand which may be inside, and finally cleared of all rubbish. He must measure to locate each Y branch or house connection from the nearest manhole. He must look to it that the manholes are built true in form, smooth in inside finish, well plastered on the outside, steps built in at the proper distance. He must see that the trench is filled, tamped or puddled, and left in good condition for travel. So much care at least must be given to the pipe sewer to insure anything like a good job. In building a brick sewer even more details are to be looked after and greater skill required on the part of builder and overseer than in the case of a pipe sewer. Some one must be on the work to note the character of the foundation as the digging progresses, for a good piece of brickwork, built on a poor foundation, is no better than a poor one, and there is no better time to see what may be needed in the foundation than when the excavation is going forward. Some one must be on hand to see that the timber foundation, or whatever may be used, is properly placed and secured. Then there is care to be taken in setting the profiles or forms for the brickwork; in noting the quality and mixture of the cement; in selecting the hardest, smoothest and best bricks for the invert; in watching the masons to see that they lay each brick to the line with a full mortar joint, and without unnecessary pounding or pushing after it is in place to break the bond of the cement; in having the bricks wet in dry weather and not too wet in wet weather; for cement hates a dry brick and will not cling to it, nor can it hold a soaked one to its place. Then care must be taken in setting the slants for house connections, lest they have insufficient support at the back and are not able to stand the weight of earth on top. The arch must be turned on a good and true center in lines parallel to the axis of the sewer, and so spaced that a full number of courses will make the arch without splitting a course. The earth must be filled in and tamped solidly at the haunches to keep the arch from cracking, and at the same time so placed as not to tear off the plastering on the outside. If there is inside or second sheeting, some one must see that it is drawn above the crown of the arch before filling, for there will most likely be a crack in the brickwork if it is left to be drawn afterwards. In case of water in the trench great care must be used to keep it away from the brickwork until the cement is thoroughly set. I never yet saw a contractor who would voluntarily keep water from flowing over the freshly laid invert, even if the water could easily be taken care of, and would be a nuisance to the masons if allowed to run, and would make him more expense in repairs and delays than the cost of pumping or bailing.

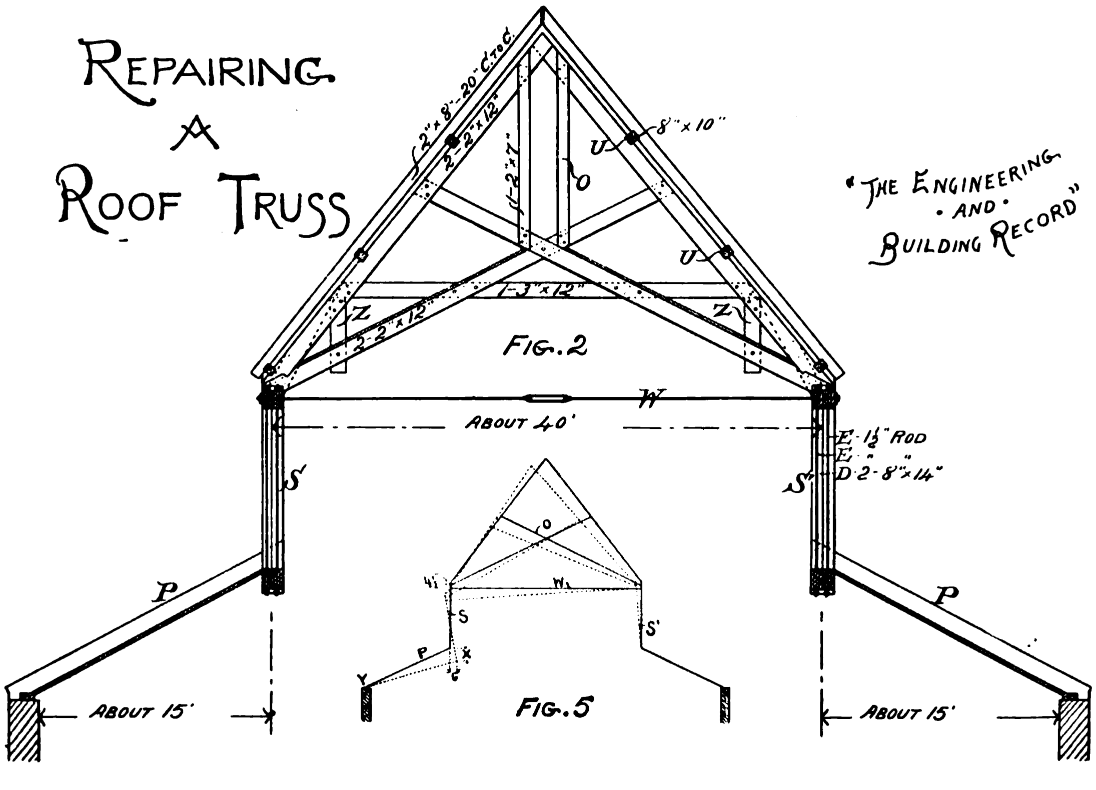
---

*A paper read by F. Floyd Weld, President of the Connecticut Association of Civil Engineers and Surveyors, published in the Transactions of the Association.

Manholes must be laid out with care to have the foundation firm and substantial, the junctions for lateral sewers built in a smooth and workmanlike manner, the head of the sewer cut in good shape, and the walls carried up to the surface in a symmetrical and smooth piece of work. Finally the sewer should be left clean, free from all rubbish, loose cement, brick chips, sand, mud or other accumulations. And now, having built our sewers with some considerable care and attention, shall we consider the duty of the engineer done, his occupation gone so far as these particular sewers are concerned, and the sewers no longer in need of supervision from anyone for all time to come? I think not. The work of building is over, but the work of running the machine is to come. It would be as reasonable to expect a complicated piece of machinery to care for and run itself as to expect a system of sewers to do their duty without some intelligent oversight. A perfect sewer, used always with the utmost care, with a stream of water of constant and ample volume flowing through it, might need no care for a number of years, but perfection in this world of sewers is rarely attained, and a steady flow of water is not always to be had.

As with persons, "Cleanliness is next to Godliness," so with sewers, cleanliness is next to success. A dirty sewer is an abomination, and if allowed to continue dirty is a failure. It all depends upon the care and oversight given to sewers whether they shall be clean or dirty, whether they shall do in a regular and continuous way the work they were designed to do, without offense or danger to the people, or shall fail to carry off promptly the refuse from our homes, and so become a receptacle for filth, disgusting to clean out and a menace to health.

There is nothing like water to keep sewers clean. If there is a lack of it the heavier parts of the sewage settle to the bottom, and cling there to decompose and send off noxious gases. This trouble is most often found in the separate system on lateral sewers, or on the ends of main lines where but few houses are connected. A flush tank at the end of such lines, arranged to discharge several hundred gallons at intervals of 4, 6, or even 12 hours, will usually keep the pipe clear. If an automatic tank is not used, frequent flushings from a hydrant or from a portable tank on wheels is very effective. Sometimes, on light grades, even where there is a good flow, it becomes necessary to clean out the sediment, and oftentimes a flush of water is not sufficient. In such cases scrapers or brushes have to be employed. I have used, with very good results, a scraper made of two wooden disks, between which a flange of rubber is bolted. This rubber fits the pipes and is drawn from one manhole to another by a rope, the rubber being flexible enough to easily pass any inequalities in the pipe. Where street water is admitted to the sewers the cleaning is sometimes quite an item; for in spite of traps on catch basins, some sediment will be carried over by the rush of water in heavy storms, and will settle at the light grades. To remove this, something more than water is necessary at times. I have used on large pipes and small brick sewers a metal scraper, made of galvanized iron, shaped like a tube, with one end funnel shape, and the other pointed. This is drawn from manhole to manhole by a rope, and raised to the surface by a small derrick. Where the sewers are large enough to admit a man, the cleaning of sand or heavy sediment can best be done by using a wheeled truck, adjusted to fit the bottom and sides of the sewer. This truck carries buckets, which, when filled, are lifted to the surface.



In making connections with sewers care should be taken to see that the pipe is properly fitted and jointed with the branch left for such use. Neglect in this respect makes much trouble for those in charge of sewers. Mud and sand often come in from an opening made to connect with a house, because it is easier to let it run into the sewer than to bail it out. Unless there is some system of license and permit for connections, and inspection of work, there will be frequent tapping of sewers at places other than the proper branches, with the attending results of broken sewer pipes, mutilated brick sewers, and pipes projecting inside to make stoppages. Careless work of this kind has been known to almost ruin a system of sewers. It has happened where it was thought no one was needed to look out for sewers after they were once built.

The best of care on the part of those in charge of sewers will not prevent misuse of them by others, and a complete choking of small pipes may result from the admission of sand or improper articles to the sewer from occupied houses or cellars in process of construction. In case of stoppage, prompt action is imperative to prevent damage to adjoining property. A useful implement to have is a rod for cleaning. Water pipe, 1 inch in diameter, cut into lengths short enough to be handled in a manhole, may be cut with a screw thread on each end, to be joined together with a union. These pieces, fitted together, will make a good rod for forcing an opening through the obstruction, and will usually start a flow of water which will gradually enlarge the opening until the sewer is cleared.

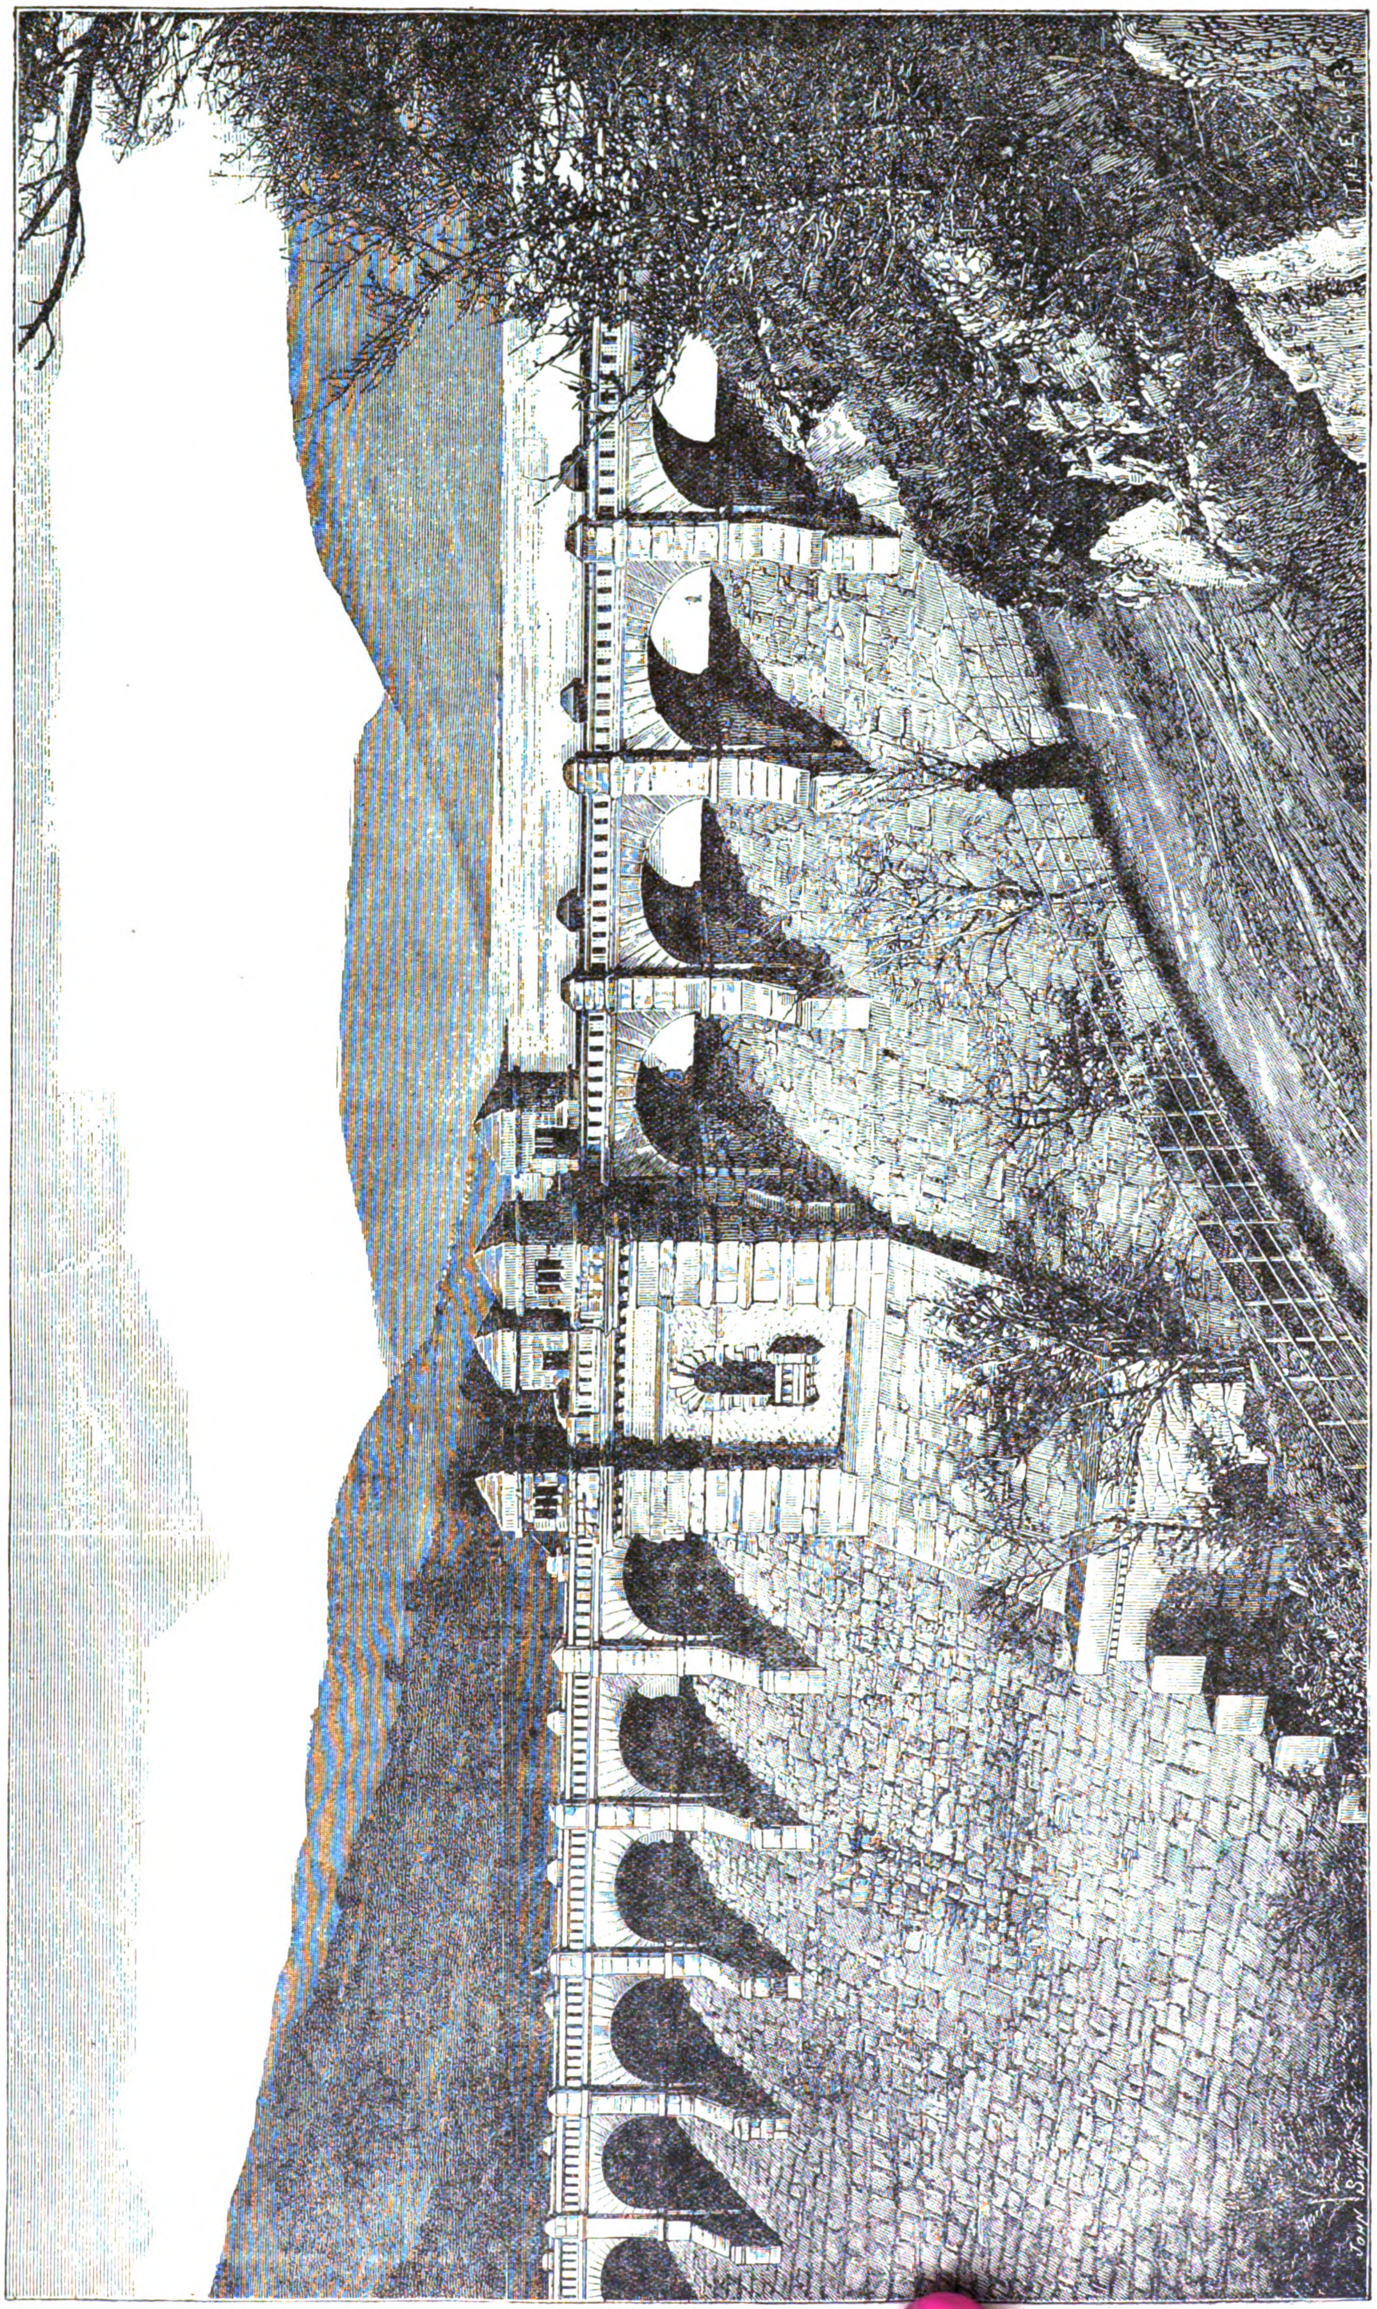
Where storm water is taken into the sewers, the catch basins need attention from the same person who has the care of the sewers; for the basins are a part of the sewer system, and should be cleaned frequently and with care, to work in harmony with the whole. The less sand found in basins at the beginning of a storm the less sediment found in the sewers at the end.

Sewers will wear out in time; but a careful inspection of all weak and hard-used places, with a little work here and there, will prevent a break, perhaps, and save many times the cost of such inspection and work.

EXCAVATING IN QUICKSAND.

An interesting experience in excavating in quicksand was recently related to the New England Water-Works Association by Albert F. Noyes, City Engineer of West Newton, Mass.

Having had occasion to make an excavation some 15 feet deep in quicksand, near buildings, it was found that if the work was conducted in the ordinary way a settlement of the foundations would be likely to occur. Mr. Noyes, therefore, adopted the following method which proved successful: The excavation, as stated, was about 15 feet deep, about 60 feet in length, and 8 feet wide. Usually below these veins of quicksand there are veins of a coarse material which form ready conductors for the water, and the vertical distance through the quicksand is usually less than the horizontal distance; the ground water has the least resistance in the vertical direction, and tends to soften and take up the quicksand with it. If the water is drawn out, or the water level lowered below the bottom of the trench, this fine material becomes compact, very much like clay, and excavations can be easily made with perfect safety, and the use of a light sheeting. In the case referred to fourteen 1½-inch pipes were used and were driven equidistant about the excavation to be made with the ordinary perforated well point, having attached outside a fine-mesh brass screen. They were driven into a stratum of coarse material from 35 to 50 feet below the surface of the ground. The pipes were ganged together, and attached to a common plunger pump, and the water was drawn down. The normal level of the ground water was within some three or four feet of the surface of the ground, so that the ground water had to be drawn down some 10 or 11 feet It was found by test tubes outside of the gang that the water could be readily held to a level, which insured the excavation being made without any difficulty. In fact, the banks were dry, and the lower portion of the excavation was very firm. In this case the well points, after use, were sold at nearly the first cost. The pipes, which were taken from the stock at the pipe yard, were returned and used again, so that there was little loss in that way; and the whole cost of driving the pipe was about $18, so that the expense of that method was really less than sinking a well outside of the excavation in the usual manner.



THE VYRNWY DAM.

THE VYRNWY DAM.

THE accompanying illustrations showing the dam which converts the Vyrnwy Valley into a lake for the Liverpool water supply are reproduced from the London *Engineer*, being intended to show the architectural rather than the engineering features of the structure. In the larger illustration is seen the upper part of a sluice valve culvert through the dam. The similar culvert on the other side passes the water which is allowed to pass down the Vyrnwy River as compensation water. The smaller illustration, from a photograph, shows the character and size of these openings. Other illustrations of the dam, with descriptions, will be found on page 202, Vol. XIII., and page 85, Vol. XV., of this journal.

IRRIGATION IN ITS RELATION TO THE PASTORAL INDUSTRY OF NEW SOUTH WALES.*

THE total area of land in New South Wales is estimated at 196,000,000 acres, and of this area 168,000,000 acres are devoted to pastoral purposes, with very precarious results owing to frequent droughts. Only 1,042,000 acres are under cultivation. These figures show the importance of the consideration whether irrigation cannot be made to assist in developing the pastoral resources of the colony. As an instance, the author mentions a case where unirrigated land on the Lower Darling, which could scarcely support one sheep to every ten acres was found, when laid down in lucerne and irrigated, became capable of supporting more than 20 sheep to one acre. In order to reduce the losses entailed by drought, sheep are frequently sent to the mountains, or to other localities where pasture is obtainable; but this course involves considerable expense and much risk, and frequently results in the loss of a serious proportion of the sheep. The total production of wool in New South Wales in 1888, an unfavorable year, was 205,000,000 pounds, and assuming that on an average for the whole quantity the diminution in value, owing to the nature of the season, amounted to ½*d.* per pound, the loss would amount under this head to £427,000. Besides the prejudicial effects of drought, wool is seriously diminished in value by the break which is caused by a sudden change in the character of the season. The alteration in the quality of wool which takes place immediately after the break-up of a protracted drought is at once apparent, even to the unpracticed eye.

In New South Wales the best rivers for irrigation purposes are the Murray and the Murrumbidgee. The district commanded by them includes only the plains between them, and a moderate area to the north and west of the Murrumbidgee. The only portion of the colony in which irrigation can be carried on with regularity, and on an extensive scale, is in the part of southern Riverina commanded by these rivers, although the author believes that the country west of the Dividing Range is, under favorable circumstances, susceptible of remunerative irrigation. The methods recommended are: 1st, the irrigation of extensive areas of the native grasses; 2d, the irrigation of limited areas of lucerne, or other crops for fodder.

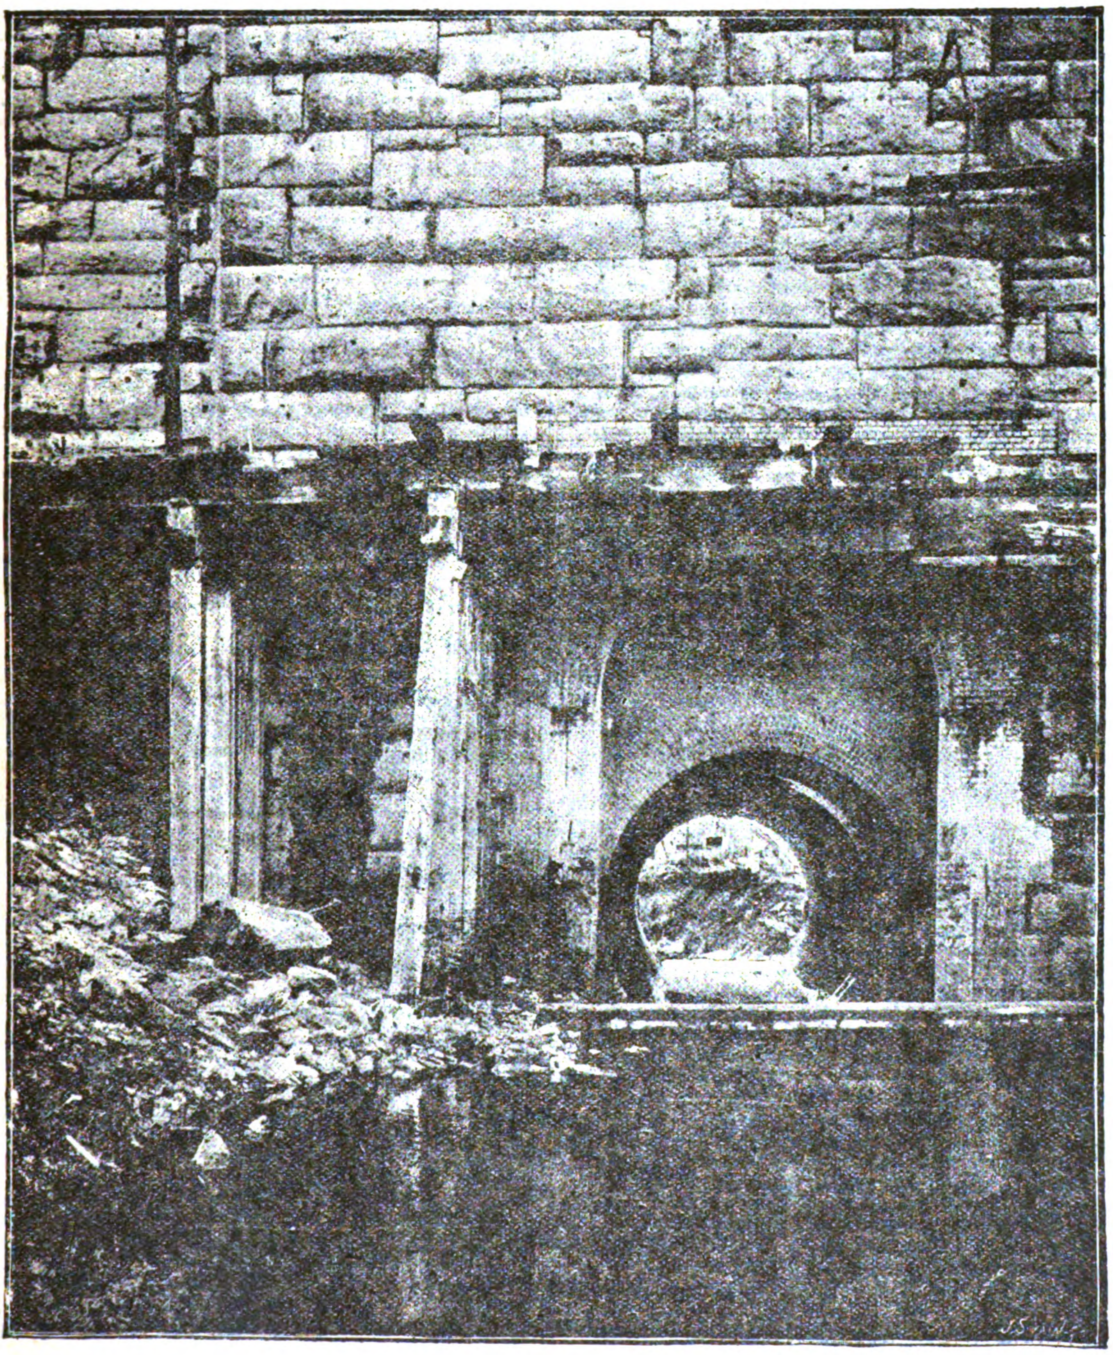
The former system is in natural operation on a large scale on the Lower Murrumbidgee, as well as on a moderate scale on the lower parts of several others of the western rivers of New South Wales. This is precisely the same process which irrigates and fertilizes the valley of the Nile. In some of the cases in which the process is exemplified in New South Wales, the inundations due to flood waters form the chief security of the "pastoralists" whose lands are thus naturally irrigated. As generally happens in the case of rivers flowing through alluvial plains, the banks of the lower parts of the rivers mentioned are higher than the land adjoining. Hence, in order to divert supplies of flood water so as to irrigate by gravitation, it is only necessary to make cuttings from the rivers with a moderate rate of fall, and extend them till they run out at the level of the natural surface. Several cuttings of this kind were made on the Jaunbung Run by Mr. Tyson, and one of them alone is stated to have cost £14,000. How profitable irrigation of the native grasses can be made under such favorable circumstances is very clearly shown in the case of Mr. J. L. Gwydir's experience. In the Corrong Run, with an expenditure of very little over £1,200, Mr. Gwydir succeeded in irrigating over 17,000 acres of grass land during every flood in the Lachlan. Taking interest and cost of maintenance together at £150 per annum, the cost of irrigating an acre amounted to only $\frac{3}{17}$*s.*, or slightly over 2*d.* In this case the profits of the first year's operations more than covered the entire outlay. Before irrigation the land referred to barely sufficed for 4,000 sheep; after the system of watering was adopted it supported 12,000 sheep and 200 horses, besides fattening 150 head of cattle.

Irrigation of the native grasses by pumping, at a gross cost of about 2*s.* 6*d.* per acre, has given a very satisfactory return under favorable circumstances in Victoria. The pumping plant in such cases was erected primarily for the irrigation of crops, but at such times as water was not required for the crops the supply was turned on to the grass lands. Under these circumstances the author maintains that the profitable irrigation of the native grasses is therefore not a question for debate, but an accomplished fact; and the only point for consideration in connection with it is the nature of the circumstances under which it is practicable.

After some remarks on the rates of water for irrigation, the process of flooding pasture land, and the production of fodder by irrigation, the author proceeds to consider the case of the River Darling. He states that the most important functions of that river are threefold—namely: 1st, the provision of reserves of fodder for the western district; 2d, the flooding of large areas of pasture; and, 3d, the provision of a permanent highway for navigation. To effect the last of these objects, a series of weirs and locks is indispensable, and the raising of the water level by this means will materially lessen the cost of pumping for the irrigation of crops. The circumstances of the Darling are extremely favorable in some important points to the construction of works for the purposes referred to. With a series of weirs at suitable intervals, the river at ordinary heights would consist of a succession of reaches of almost still water. The same weirs would also hold up the water in the river to such heights that flooding the land by gravitation could be carried out in the manner already adopted on the Lower Lachlan. The conservation of the waters of the Macquarie is stated to afford "remarkably favorable conditions for the diversion and storage of floodwater," and the author gives at length the conclusions of the second report of the New South Wales Water Commission, which advocates the judicious expenditure of £300,000 in diverting supplies from the Macquarie, and distributing them between that river and the Bogan.

The paper concludes with some general remarks on the progress of water conservation in Victoria, the principal irrigable areas in New South Wales, water legislation, the examination of engineers, the causes of the backward state of water conservation, and statistics relating to losses therefrom.

In the discussion following the paper the importance of the subject was generally admitted. In regard to the suggested interference with navigation which might result from the removal of so large a quantity of water from the rivers, it was stated that in Victoria people were quite reconciled to the idea of navigation being seriously interfered with, believing that much greater good would result from irrigation.



THE VYRNWY DAM—CULVERT AT NORTHERN END.

LAYING SUBMERGED PIPE AT GREENVILLE.

G. S. WILLIAMS says, in the University of Michigan *Technic*, that in the construction of the water-works at Greenville, Mich., during the summer of 1888, it was necessary to lay a line of 12-inch pipe across Flat River, some 200 feet, in water about 4 feet deep. By manipulating dams above and below the point we were able to get the water down to about 2 feet in depth. Eighteen lengths of 12 inch pipe were laid in place in the water and then raised by means of jack-screws placed on horses above, from which the pipe was suspended, until the joints were out of water. The pipe was then set to the proper curve and caulked with lead in the usual manner, after which it was lowered by means of the screws worked simultaneously, until parts of it bore on the bottom. The steam fire engine was then brought to the crossing and two lines of hose taken out with 1⅛-inch nozzles, streams from which at a pressure of about 140 pounds at the engine were played upon the bottom underneath the pipe and the earth was scoured away until the pipe came to a bearing for its entire length. The pipe was then released from the screws and the jets were worked along the pipe until it was buried its full depth in the river bottom, which consisted of sand and gravel. The jets worked better in the gravel than in the sand. This method of laying the pipe was found to be much more economical than by means of a coffer dam, and was in every way successful. The pipe was tested, before being covered, at a pressure of 160 pounds per square inch, and but one joint was found to leak at all, and this leak was immediately stopped by a few strokes of the caulking iron. It appeared, however, that in sinking the pipe further, a nozzle or pipe that was bent to a curve would be preferable to a straight one. In some places the pipe was sunk to a depth of 18 inches.

From the river to the pump house the line extended about 450 feet across a flat where quicksand was encount[illegible] a depth of less than 2 feet. The pipe was laid at the top of the quicksand in a line parallel to grade as nearly as possible and the entire length caulked. It was then lowered to grade very successfully by putting a man on each side of each length and having them dig on both sides of the pipe along the entire line at the same time. In this way we succeeded in lowering the pipe in some places as much as four feet, and none of the joints were sprung so as to leak in an open ditch under 160 pounds pressure. Three hundred feet of 16 inch suction was laid in the same way.

---

*A paper by H. G. McKinney, M. Inst. C. E., in Journal and Proceedings of the Royal Society of New South Wales, abstracted in Excerpt Minutes of Proceedings of the Institution of Civil Engineers.

On these works it was not infrequently the case that a joint had to be run when half or two-thirds of it was under water. In such cases we used the ordinary clay-rolls making two openings at the top. We next poured in a small quantity of oil, kerosene will do, but a thicker oil is better, and then slowly poured in the lead at one of the holes. The water would be forced out, the layer of oil apparently keeping it away from the lead and as perfect a run would be obtained as in a thoroughly dry joint. This method was used on all sides from 16-inch to 6-inch and was found uniformly successful, there being neither explosion nor spattering.

THE AIR OF THE ST. GOTHARD TUNNEL.*

DURING the early days of the working of the Saint Gothard Railway, when it was uncertain whether the natural circulation of the air would be sufficient for the removal of the smoke, or whether artificial ventilation might be necessary, a system of temperature observations was organized by placing thermometers in the 15 refuge chambers in the tunnel, which were observed and recorded at intervals of eight hours by the tunnel watchmen, who noted at the same time the strength and direction of the air currents and the density of the smoke in the air, the external atmospheric conditions being simultaneously recorded at the meteorological stations at the Göschenen and Airolo ends of the tunnel. These observation sheets were sent into the engineer's office monthly and at the end of the year the results were plotted as curves for the Swiss Railway Department. The present paper contains an abstract of the results of six years' observations — 1883–1888—from which it appears that the maximum temperature in chamber No. 8, in the middle of the tunnel, has been practically constant 22.8° to 23.4° Cent., while the annual minimum shows a small continuous diminution from—

16.4° ....in March, 1883 to
16.0 ....in February, 1884
15.0 ....in February, 1885-6
14.8 ....in December, 1887
14.5 ....in January, 1888

During the driving of the tunnel the average annual temperature observed in the headings was as follows :

	1876.	1877.	1878	1879.	1880.
Göschenen end—					
During boring	19.4°	21.1°	24.0°	26.4°	30.3°
After firing	20.8	23.4	26.0	29.3	31.2
Airolo end—					
During boring.... ...	23.1	25.0	25.8	28.2	29.3
After firing	26 6	28.5	29.3	30.7	31.0

Before the joining of the headings on the 29th February, 1880, the mean temperatures in the Göschenen end were 26.6 and 29.6 degrees, and in that of Airolo 29.2 and 31.6 degrees, respectively, as during the last month the amount of air delivered in the ends was largely increased, but this only reduced the air temperature to about 1.7 degrees below that of the rock. The latter was in February, 1880 :

At 7,635 meters in on the north side under 1,704 meters of cover, 30.6°
7,041 " " south " 1,480 " " 29.4

The mean rock temperature of the entire length of the tunnel was originally 23.43 degrees, the mean air temperature February 29. 1880. 21.60 degrees ; on February 11, 1881, 19.3 degrees, and on February 11, 1882, 14.2 degrees. These figures show very clearly the diminution in the mean natural temperature of the whole tunnel.

Later determinations of the rock temperature made since the opening of the line gave the following results :

Date.	7,300 meters N. in bore-hole 1 meter deep.		7,050 meters S in. boring 1.1 meter deep.	
	Air.	Rock.	Air.	Rock.
July, 1882............. ..	20.10°	23.9°	21.0°	24.5°
July-August, 1885.. ..	19.65	22.2	20.6	23.0
Diminution.......	....	1.7	....	1.5

As regards the movement of the air, the observations were confined to noting the direction of the current and estimating its strength, which was noted as strong, moderate, weak, or calm. The natural draught in the tunnel results from differences of air pressure at the two ends, the wind blowing from the side of highest pressure, and its strength being proportional to the square root of the difference of the two pressures; the column of 36 meters due to the difference in the relative level of the two ends being sometimes in favor and sometimes against the prevailing wind, according as it is lighter or heavier than the external air. The combined effects of differences of temperature and moisture at the two ends resulted, during the five years' observations, in the following average distribution of the air currents, the draught being either continuously north or south for some time, or changing from one to the other direction at short intervals. In the latter case there are of course periods of calm, but none of them have ever lasted for more than half a day.

Year.	Days of Prevailing North Wind.		Days of Prevailing South Wind.		Days with Alternating North and South Winds.	
	Winter.	Summer	Winter.	Summer	Winter.	Summer
1883	70	75	45	29	66	80
1884	60	82	56	42	67	59
1885	51	80	61	33	67	68
1886	55	70	60	54	67	59
1887	65	79	45	40	72	64

Winter signifies the period October to March, and summer April to September, inclusive.

From these figures it appears that northerly wind is most prevalent in the summer, while in the winter months the draught is tolerably equally divided between north and south. The days on which rapid changes in direction are observed differ but slightly with the season.

The prevailing external wind at the tunnel stations appears to have no effect upon either the duration or the strength of the current in the tunnel, neither is the distributing influence of a passing train acting as a piston more than local and insignificant.

The smoke observations were classified into whole and half days of smoky air; transitory smoke and air free from smoke. These are plotted upon curves, but given without numerical data. From these figures it appears that continuous smoky days are more prevalent at the south than at the north end, and in summer than in winter; and that the number of clear days is similarly larger at the north than the south end, although the difference is but slight. The middle of the tunnel is completely free from smoke for only a very small number of days in the year; but, on the other hand, the number of entirely smoky days is much less than at the ends, while the effect of the transitory smoke is most constant at that point. The most unfavorable conditions are observed on days when the wind is only slight or unsteady in direction. The work necessary for the maintenance of the way, etc., is, as far as possible, confined to days of strong prevailing winds in one direction, or the night hours when the traffic is confined to two express trains and the smoke is at the lowest. Passengers traveling through with the carriage-windows shut suffer no inconvenience from smoke. The six years of observation having proved that the ventilation of the tunnel is practically continuous in one direction or other, the practice of recording the smoke has been discontinued, and the author considers that there will be little further utility in continuing those on temperature and air-movement.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

THE VALUE OF TRITURATION IN REPAIRING MACADAM ROADS.

NEW YORK, July 7. 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: When I read in Mr. Owen's article on Repairs to Macadam Roads, "the constant trituration, if I may so call it (and it is a good word), being of far more efficiency than the dead weight occasionally applied," it occurs to me to ask, if this trituration is so efficient an element in road repairing, screenings being discarded, why should Mr. Owen insist on wearing out the hoofs and shoes of New Jersey horses in an effort to triturate off the hard and strong angles of his admirable Orange Mountain trap when the many mountain streams and glacial moraines of his State afford him such a store of well triturated and thoroughly rounded material?

I ask this question knowing, as every one does who has seen his roads and read his essays on the subject, that Mr. Owen's roads are very much better than his theories. They are very good roads, with the single exception that they are a little soft during a prolonged spell of wet weather or when they are alternately freezing or thawing. They, however, are not strong, homogeneous roads, and through their method of construction they must be thicker than if they were strong and homogeneous.

Quoting what I have before said in your columns: The points which should have emphasis in building macadam roads are—a strong and tough stone being obtained, if possible:

First.—Thoroughly compacting the soil by rolling before the broken stone is applied.

Second.—Clean binding, which, if possible, should offer as great or greater resistance to crushing as the stone used in forming the wearing surface; in contradistinction to either filling or lubricating material.

Third.—The use of a steam road roller of competent weight.

Fourth.—The combination of these two in connection with sufficient skill, resulting in a wheelway that is without voids in its lower surface, inviting the percolation of mud from below, that is sufficiently compact to shed rain and has some cohesive strength; while the clean binding, which is strenuously insisted on, prevents movement of the stones among themselves and keeps their angles from wearing off.

Such a road may be safely made four inches thick on nearly all soils, even when designed for the heaviest traffic. A road, on the contrary, of that thickness, filled with clay, the angles triturated by the trampling of horses' feet and the whole loosely compacted by a horse roller will, if laid on clay or a clay loam, break to pieces in the spring or a wet time, and the stones, like plums in an over-fluid porridge, will sink, and the porridge will be on top. Long continued experience of the fact last above stated has made Mr. Owen a strenuous advocate of Telford foundations. And the man who is going to build such a road and does not put it on a foot or more of carefully placed and thoroughly wedged Telford foundation, or on at least four inches of properly made macadam road, is not doing justice to his employer. On either of the above-mentioned foundations a clay-filled road will not break through, but the stones will wear upon one another.

It is painful, also, to differ as to "the only real argument to be used in favor of a steam roller." No one, I think, can watch the action of the driving wheels of a steam roller without noticing that on uncompacted stones the wheels draw the stones, so that those passed over by the driving wheels present a different appearance from those passed over by the steering wheel, which has only a rolling motion. I think this drawing action of a driving wheel is very effective in reducing the volume of void spaces which should be filled with binding material. Mr. Owen's contention that a patch on a macadam road shows premeditated negligence or ignorance may be a slightly extreme statement, but with trap roads patching is not as necessary as when softer stone is used. When softer stone or gravel is used, however, patching is an economical and almost necessary mode of keeping the road in good surface, and it should not be neglected with the hardest road when depressions of comparatively small area appear from any cause. EDWARD P. NORTH.

THE PROPOSED WATER-WORKS CRIB IN CHICAGO.

BOSTON, MASS., July 7, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: The Chicago Water Works system is at present being extended by the building of an additional tunnel four miles into Lake Michigan. At its terminus, in 40 feet of water, a huge crib, estimated to cost about $300,000, is to be built up to above the water surface, and provided with a lighthouse and keeper's residence. Public reports do not state the reasons for having such a structure, built simply for the purpose of guarding the intake. It would be of much interest to know why this large expense is being incurred. Other cities are dependent upon lake water for their domestic supply, and if such artificial islands are really necessary in every case, the reason should be well known. Are any of the readers of your valuable paper able to throw some light thereon? B. W. H.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department.* Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

PUBLICATION ON CONSTRUCTION OF CANAL LOCKS AND GATES.

WILLIAM J. SILVER, of Salt Lake City, Utah, writes: "In regard to the inquiry (page 346, Vol. XXI.) on the construction of lock and waste gates, the past files of the *Engineer*, London, have quite a number of examples of large size and recent construction. Last year there was a description of some large sluice gates raised by water power at the Lough Erne drainage, Ireland, and in the issue of May 9, 1890, is a description of sluice gates 30 feet wide, 10 feet lift, raised by hand gear, on the Manchester ship canal. Given the fall available, and the weight of the gate it is a plain matter to arrange gearing for a turbine to lift it."

DOMESTIC PLUMBING HEATING LIGHTING & VENTILATION ENGINEERING

PLUMBING IN THE UNION TRUST COMPANY'S BUILDING, NEW YORK.

PART II.*—DISTRIBUTION DRUMS, SEWER VENTILATION AND PIPE SUPPORTS.

THE supply of hot and cold water to all parts of the building is controlled entirely from the distribution drums in the cellar, shown in Fig. 5. They are of galvanized steel, about five feet long. *v* is for hot water under tank pressure and *b* and *c* for cold water under tank and street pressure, respectively. Tank water is received through the 4-inch pipe *n* and its 2-inch branch *o*. Water under street pressure is received through a 2-inch branch *q* from a 4-inch pipe *p* to the suction tank C, Fig. 2 (page 77). Live or exhaust steam is delivered through a ¾-inch pipe I to the 2½-inch pipe *a*† and, after heating the water in the drum *v*, escapes through a ½-inch pipe *s*.

The pipe A is a hot water 1-inch supply to two slop sinks and B is a 1½-inch supply to all other slop sinks. C and D are 1-inch supply pipes to the president's and directors' rooms. F is a ¾-inch and E and G are ½-inch hot-water return-circulation pipes from the tops of the lines B, C and D and connect above its valve with the sediment pipe *m* of the drum *v*. The pipes H J K and L are 1-inch tank cold water supplies to different lines of wash basins. M is a 1½-inch supply pipe to a group of wash basins and urinals, N is a 1½-inch supply pipe to a group of basins, urinals and slop sinks, and O P Q and R are 1-inch supply pipes to lines of wash basins. S is a 1-inch supply pipe to the directors' room. T is a 1-inch supply pipe to the president's room. U. is a 1½-inch cold-water supply pipe under street pressure to a basement toilet room and V is a 1-inch supply pipe to the same. W is a 1½-inch supply to another basement toilet room. Y is a 1½-inch supply pipe to the elevator tank. Z and *d* are 1-inch supply pipes to front and rear cellar sinks; *j* is a 1½-inch by-pass connecting the drums *b* and *c*, the valve (*k*) of which is usually closed to keep the two systems separate, but may be opened to admit tank water to the drum *c* if the street water is turned off. The lines of pipe, W and U, are generally supplied by street pressure, the valves *w* and *u* being open and the valves *x* and *y* closed. By reversing these valves, however, the supply is under tank pressure.

All the rising lines may be emptied through their valves *i i*, etc., into the drip pipe *g g* that discharges into the trap of a 5-inch rain water leader *z*. The drums *v*, *b* and *c* may also be emptied by branches *m m m*, through the pipe *g*; *t t*, etc., are pipe legs supporting the drums; *f f*, etc., are pipe hangers supporting the horizontal lines from the iron floor beams; *p* is the 4-inch pump delivery pipe to the roof tank.

Figure 6 shows the method of supporting stacks of cast-iron pipes from the iron floor beams by the welded iron strap S, carefully fitted just under the hubs.

Figure 7 shows the special fresh-air inlet at the main sewer trap. Each of the main house sewers C C has a branch A to a double Y connection D at the sidewalk grating and any dirt or other obstruction can be very readily removed through its cleaning hole at B and another at E in the double Y connection F with the main sewer.

The plumbing in this building was done by Byrne & Tucker, of New York City.

---

* Part I., Roof, Suction and Drip Tanks and Pump Connections were illustrated in the issue of July 5.

† The pipe *a* and connections are similar to pipe *a* of Fig. 1, page 11, in the description of "Plumbing in the Mechanics' Bank Building."

WATER HAMMER IN STEAM PIPES.

WHAT is known as water hammer action is familiar to every one who has had to do with the use of steam for heating purposes. The astounding noise, the violent shocks, the excessive vibrations which are set up if a little steam is formed and is then condensed in the pipes, are well known. Striking instances of water hammer action are supplied when marine boilers are blown off or when scumming takes place, so that steam passes into the sea. It is common for a large ship to shake from stem to stern at such times. Cabin doors will open and shut, crockery will go adrift, and the noise made by the water fighting its way into the vacuum and the steam trying to get out, being condensed in the act, echoes through the ship. Scumming is known to sometimes be positively dangerous from the way in which it shakes the boilers, bringing the scale off the tubes in flakes upon the furnace crowns where it adheres in such quantity that the sheets are liable to become red hot and come down.

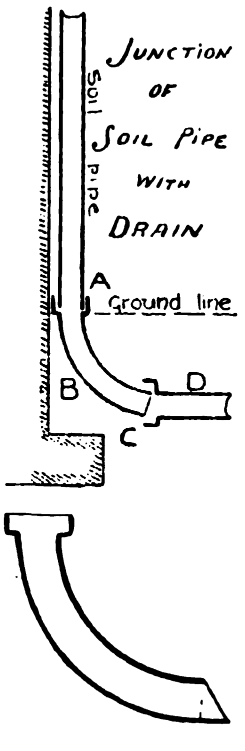
According to an article in the London *Engineer*, a curious experiment was tried several years since by an English engineer. He took a large funnel fitted with a stop-cock and screwed the pipe into the top of a boiler containing steam of about 40 pounds pressure. He then filled up the funnel with cold water and opened the stop-cock. It would naturally have been predicted that the steam would have blown all the water out of the funnel. It did nothing of the kind. On the contrary, the water rushed into the boiler. As a result of this and several other experiments a boiler feeder was designed and patented and worked with tolerable success. It was found, however, that it was not certain in its action, and, the injector coming into high favor at the time, the inventor spent no more money on his ingenious idea. The inrush of the water was due to the fact that the steam condensed in the long pipe of the funnel and "water hammer" action then drove the water into the boiler. Practically just below the cold water there was always a vacuum, into which the water was driven by its own weight and the pressure of the air.

JUNCTION OF SOIL-PIPE WITH EARTHEN DRAIN.

A CORRESPONDENT of the London *Builder*, in a recent communication to that journal, says:

"Vertical soil pipes frequently discharge their fluid from great heights. At the foot of the soil-pipe the vertical stream is diverted to a nearly horizontal direction by means of the earthenware *bend* which unites the vertical soil-pipe with the underground drain-pipe.

"Great care is generally exercised by the architect, clerk of works, and builder, to make a good joint where the plumber's soil-pipe joins the earthenware bend. But the danger of leakage is much greater at the joint of this earthenware bend with the drain into which it discharges. I believe in the vast majority of cases if this last-named joint were examined a few years after the pipes have been in use, it would be found to be discharging a large percentage of the sewage into the foundations; and in this way converting the sites of single dwellings and of whole towns into concealed cesspools!



"I speak from experience, many cases having come under my own observation.

"This evil is not necessarily due to downright carelessness, though the more carefully drains are laid, the less they will settle and shift afterwards. Let it be assumed the drain has been so well bedded that the pipe, D, remains stationary without settling in the least degree, and let the pipe-bend be bedded on clay, at B, with considerable care. Still the impact of the continually-repeated discharges of fluid, descending from a considerable height upon B, compresses the bedding of clay, and eventually forces the bend so far backward as to dislocate the joint of bend with D, discharging a large percentage of each flush from the water-closet through the joint at C into the foundations.

"I have seen gable walls split from foundation to coping from having their foundations sapped in this filthy fashion.

"Thanks to this heel of Achilles-Sanitarius, now, in 1890, in every large town, I believe there are thousands of dwellings, including those of the higher classes, standing thus on their own cesspools.

"How can this be remedied?

"I suggest the absolute necessity for bedding the upper end of pipe D, and the whole of the bend, *on solid concrete of considerable horizontal spread or area*. I also suggest that drain-pipe makers form the outfall ends of bends, not *square*, as usual and as here dotted, but to a slight *bevel*, as per firm line on sketch, giving the pipe, so to speak, a slightly longer underlip than is now customary. And I also suggest that the architect or clerk of works and the surveyor for the local sanitary authority should henceforth personally *examine* the joint C of *old as well as new* drains; and I think if a general examination of such joints were instituted a vast danger to public health would be exposed in such hideous repulsiveness as to hasten a general overhaul and repair of such open joints as are

now secretly vomiting death and corruption wholesale amongst us."

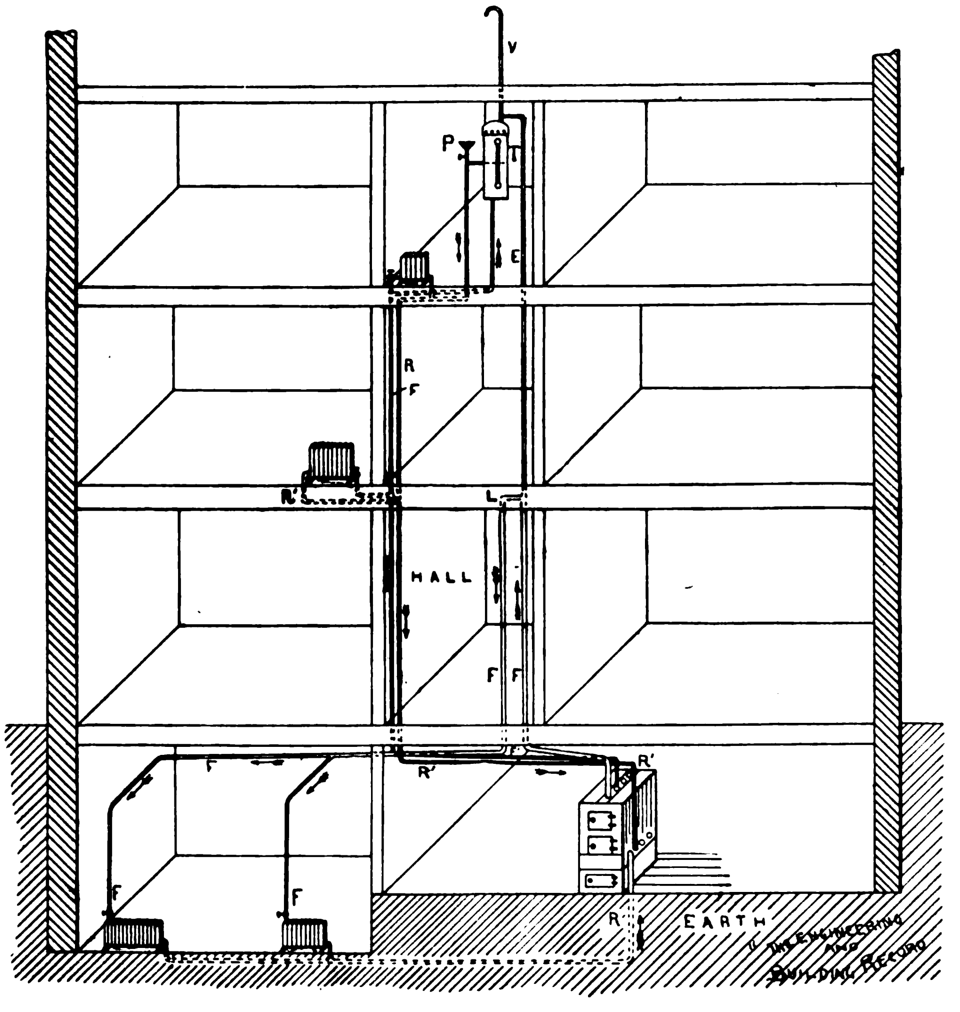
[Such work as is here referred to is not permitted in cities of the United States which enforce their plumbing regulations, though it often exists elsewhere. Iron bends should be insisted on, properly calked and supported, and exposed to view and readily accessible.]

HOT-WATER RADIATORS BELOW BOILER LEVEL.

AS SHOWING how to get circulation in hot-water radiators placed below the level of the boiler, the accompanying diagram illustrating the method by which the problem was solved in a large building recently fitted up in New York City, applied to one of the Boynton Furnace Company's hot-water boilers, will be interesting. The illustration represents a sectional perspective.

It will be noted that the cellar floor is considerably lower at the left than at the right, and in that portion it was desired to place several radiators, though it was necessary that the boiler should be on the higher level. The flow pipe F from the boiler was, therefore, first carried up to the top of the first story, and then down again, forming the loop or syphon F L F, connection with the cellar floor radiators being made as shown. The flow pipe branches enter the radiators at the top and the returns R are taken off at the bottoms, the layout of the piping being readily understood. From the highest point of the loop or syphon F L F an escape pipe E was led, connecting, on the uppermost floor, with the pipe V which comes from the expansion tank T. The vent pipe V leads to the roof. Where indirect hot water heating is used, the indirect radiators being but slightly above the level of the top of the boiler, the plan of first running up some distance and then coming down with the flow pipe, as in this case, has been well recommended.

In the published diagram the pipe connections are shown, also to one of the radiators on each of the highest two floors the pipes, both flow and return, F^1 and R^1, being shown full black to avoid confusion. These pipes, as will be noted, form an independent circuit by themselves, and the expansion tank connections are so made that even with the radiators shut off there will be a steady circulation. The arrows indicate the directions of flow and make the diagram clearer. To avoid the confusion resulting from several lines of pipe running together no first-floor radiator connections have been shown. For this floor also, however, an independent circuit is used, better results being claimed for this arrangement. Water may be supplied to the system through the funnel P. The radiators in the plant under consideration have valves on the inlets only, the valve disks, moreover, being perforated so that even when the valves are screwed down tightly circulation is not entirely stopped.



HOT WATER RADIATORS BELOW BOILER LEVEL.

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

RUSTING PIPE AND SEWER GAS.

A NEW YORK architect writes: "A galvanized iron leader pipe from a piazza connects with a drain to the sewer. After about three years' use it has rusted or been eaten through from the inside. The plumber says 'sewer gas.' The opening to the pipe in the gutter is about eight feet away from a bedroom window opening on to the piazza roof and always open at night, but as no ill effects have resulted to the occupant of the room, may not the destruction of the pipe be attributed to some other cause than sewer gas, and what? If not, is there in sewer gas an element of danger to galvanized iron leader pipes not harmful to human beings? The pipe has been ordered disconnected and the opening in the drain closed."

[Though not so stated, we infer that there was no trap on the rain leader, and that the air from the drain had free passage through the leader. The mixture of gases, commonly termed "sewer gas," more properly sewer air, produced by the decomposition of sewage, is made up, chemically, of some or all of the following gases, mixed with air in varying quantities and proportions dependent on the nature of the sewage and its rate of decomposition: Nitrogen, some hydro carbons (marsh gas, etc.), sulphuretted hydrogen, ammonia, sulphide of ammonia, carbonic acid, carbonic oxide, and complex organic vapors and vapor of water.

In addition to its chemical constituents the sewer air contains microbes or bacteria floating in suspension, the presence of which, from a sanitary or hygienic standpoint, far outweighs all consideration of the chemical constituents of the "sewer gas." Among the gases enumerated two or three are positive poisons if inhaled in quantity, and one or two would suffocate if breathed in large amounts. The conditions stated in the query make it improbable that the chemical constituents alone of the drain air could have seriously affected the health of the occupants of the neighboring bed-rooms or produced disease; from this cause alone the effect to be expected at most would be a general loss of vitality and a lowering of what physicians call "tone." The chemical constituents, on the other hand, would alone be active in corroding the metal of the leader pipe, the sulphur compounds offering especial advantages in this way. The microbes or bacteria carried by the drain air might be harmless to health or might be fatal according to the kind of bacteria present. If the varieties producing disease were present a single night's exposure to the air from the leader might prove fatal. If, on the other hand, the disease variety were absent no harm might result from years of exposure other than would come from air diluted with inert or comparatively weak impurities. It is apparent, therefore, that the health of the bed-room occupants and the "life" of the metal of the pipe are affected by entirely different causes, and causes not necessarily related.

The question is reduced, therefore, to determining whether the metal of the leader is affected by any of the chemical constituents of the drain air, and as to this there is no reason to doubt that the sulphur compounds would materially hasten corrosion if present in even comparatively small quantities. It is with a view, in part, to the prevention of the corrosive action of "drain air" that the avoidance of all "dead ends" in house plumbing is insisted upon, and that provision for the free circulation of air through all mains and lateral and branches is demanded. The plumber is therefore probably right in attributing the corrosion of the pipe to "sewer gas." As bearing upon this matter in a practical way there may be mentioned a statement made by J. P. Gallagher, of St. Louis, at the recent meeting of the Master Plumbers' Association in Denver. Mr. Gallagher presented a photograph of what was probably the first soil-pipe carried through a roof in his city. The pipe was put in by Mr. Gallagher himself in 1871, there being about 30 feet of it above the highest fixture, all of which was found perforated like a sieve when taken out in the spring of 1889. The pipe when put in was about ¼-inch thick. The pipe below the fixtures was of the same quality, sinks and water-closets being connected on each of four floors. This portion was intact, tending to show that the pipe through which the water passes will last much longer than the pipe carrying off the vapors.]

BATH WATER HEATER WANTED.

MORTIMER C. MERRITT, architect, of New York City writes: "Can you send me the address of the maker of a small water heater, using gas, to be placed in a bath room to heat the water for a bath?"

[In response to a similar inquiry published in this journal some months ago, correspondents wrote that the Sheldon Manufacturing Company, 14 West Twenty-third Street, New York City, or the Detroit Heating and Lighting Company, Detroit, Mich., would furnish the heater indicated.]

TRADE PUBLICATIONS.

CHAIN BLOCKS.

A REPORT on the efficiency of chain blocks, made by Prof. Robert H. Thurston for the Yale and Towne Manufacturing Company, of Stamford, Conn., has just been issued in pamphlet form. In connection with it are given, also, descriptions and illustrations of Weston's "Triplex" spur gear block, and of the "Direct" differential pulley block made by the above company. Tables of prices, capacities, weights, etc., are added.

IRON ROOF TRUSSES AND IRON BUILDINGS.

Owing to the increasing demand for information regarding iron roof trusses and iron buildings the Indiana Bridge Company, of Muncie, Ind., have prepared and issued a special catalogue devoted to this branch of structural iron work. It is profusely illustrated, showing various types of roof trusses and designs for building frames, and gives explanatory particulars with each set of illustrations.

CORRUGATED SHEET METAL.

Corrugated and other sheet metal building material is treated of in an interesting manner in the latest catalogue of the Cincinnati Corrugating Company, of Cincinnati, O. The various applications of corrugated sheet metal are illustrated by numerous engravings, and data of general and trade interest are given.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

CONTRACTING INTELLIGENCE

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." *Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.*

For works for which proposals are requested see also the "Proposal Columns," pages i-ii-x-95.

WATER.

For Additional Water Items see Proposal Columns

Hempstead, L. I.—The Hempstead Township Water Company has been incorporated. The capital stock is $20,000. The trustees are John Lockwood, John C. Lockwood and George W. Lockwood, of Jamaica; D. D. Williams, of Haverstraw; Frank G. Lockwood and Paul Campaignac, of Brooklyn, and Samuel A. Souther, of Bay Shore.

Springfield, Mass.—On July 7 the Common Council voted to issue bonds for $125,000 for improving the water supply.

Norwich, Conn.—At a special Corporation meeting, held on July 7, a resolution was passed directing the trustees to employ a competent engineer to make survey and submit estimate of cost for repairing the bank of the Canaswacta Creek, so as to prevent another overflow. The report is to be submitted at an adjourned meeting to be held on July 28.

Toledo, O.—A number of water main extensions have been ordered in this city.

Sioux City, Iowa.—A press report from this place says that "steps have been taken toward the building of new water-works that will draw the supply from the Missouri River."

Wheeling, W. Va.—There is talk of erecting a fountain on Chapline Street, in this city, to be supplied by running a pipe to a spring at the head of Fourteenth Street.

Cleveland, O.—At a meeting of the Board of Water-Works Trustees, held July 7, bids for wrought-iron pipe to be used in the tunnel at the foot of St. Clair Street, were received from the Cleveland Steam Boiler Works for $24,940, Smith & Teachout $22,498, and the Variety Iron Works for $19,522, to whom the contract was awarded.

Yoakum, Tex.—It is proposed to construct a system of water works at this place. Address M. G Ranney, City Clerk, as above.

Chicago, Ill.—The Common Council has authorized the Union Stock Company to construct a water tunnel not exceeding six feet in internal diameter, from a point in Lake Michigan not more than a mile from the west shore of the lake to the stockyard, for the purpose of supplying water to the stockyard and Transit Company

Brooklyn, N. Y.—The Board of Aldermen has authorized an expenditure of $65,000, or so much of this sum as may be necessary, for the construction of a water standpipe on the ground of the Prospect Height Reservoir; also an appropriation of $19,000 to defray the cost of the new water-works extension.

Boston, Mass.—At a meeting of the Board of Aldermen, held on July 7, a petition was received from the Water Board asking for an appropriation of from $100,000 to $150,000 for the extension of its water mains. The communication stated that unless this sum was appropriated the Board would be compelled to stop necessary work.

Gouverneur, N. Y.—Plans are being prepared for the construction of a system of water-works at this place. Address C. N. Reynolds, City Clerk, as above.

Muskegon, Mich.—For information concerning work here in charge of Chester B. Davis, of Chicago, see our Proposal Columns.

Madison, N. J.—The Common Council has decided to locate the water-works at Union Hill, and $60,000 in bonds will be issued for that purpose.

Ludington, Mich.—C. G. Wing, President The Ludington Water Supply Company, writes: "We are about to project an intake pipe 20 inches in size into Lake Michigan as a source of water supply."

Bar Harbor, Me.—The Eden Water Company has consulted with M. M. Tidd, the Boston engineer, in the matter of constructing a new system of water-works for this place.

Washington, R. I.—The contract for furnishing 50 car loads of 18-inch pipe for water-works at this place, and for about 15,000 feet of sewers at Valley Falls and Lonsdale, has been awarded to Henry A. Warner, of New Haven, Conn.

Water-Works.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Coshockton, O.; Somerset, Ky; Hinton, W. Va.; Mohawk, N. Y.; Saulte Ste Marie, Ontario, Can.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

Boston, Mass.—The Common Council of this place has authorized the appointment of a special committee and employment of an expert engineer to locate a sewage pumping station and irrigation field.

Galion, Ohio.—J. B. Weddell, City Civil Engineer, writes that proposals will shortly be advertised for constructing about 9,000 feet of pipe sewers.

Chicago, Ill.—The Drainage Commission of this city has authorized Chief Engineer Cooley to employ a number of assistants, and it is expected that work on the new scheme will begin at once.

Syracuse, N. Y.—The following bids for furnishing cement sewer pipe for Burnet Park have been opened: Martin V. Sullivan, $878.95; Elson J. Stearns, $857.25. The contract was awarded to Elson J. Stearns.

New Orleans, La.—A bill likely to become a law of Louisiana seeks to create a drainage system for this city by establishing a Commission of Public Works, with the Mayor at the head, which shall have power to adopt and carry out a comprehensive sewerage scheme, levying a tax of one mill on the dollar for two years for the purpose and borrowing not more than $100,000. The City Engineer is to be chief engineer of the commission.

Davenport, Iowa.—A considerable number of gutters are ordered constructed in this city.

Sewers.—See our Proposal Columns for information regarding sewers and sewer construction at the following places: Key West, Fla.; Gardner, Mass.; Brookline, Mass.; Fredonia, N. Y.; Pittsburg, Pa.; Albany, N. Y.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

Granby, Conn.—The contract for the new bridge at Craig Mills, with abutments, has been let to John Forsayth, of Mechanicsville.

Toronto, Can.—The Grand Trunk Railway has agreed to build two 18-foot culverts over the conduit pipes at the Beach. Chief Engineer Hobson and City Engineer Haskins have held a conference regarding same.

Atlanta, Ga.—The County Commissioners have adopted a resolution looking to the bridging of the railroad crossings at Bellwood and Collins.

Foreman, N. D.—The following bids for building a bridge over Wild Rice River were received by Charles Afdem, County Auditor July 7: Charles Watkins, Ransom City, N. D., $145; F. H. Skaarer, Cayuga, N. D., $115; Gilbert Thompson, Ransom City, $161.

New York City.—The Secretary of War has notified Mayor Grant, of this city, that the Third Avenue bridge over Harlem River must be removed or altered by January 1, 1892.

Mt. Vernon, O.—The following bids for the construction of numerous iron bridges were received by the Board of County Commissioners, June 30: Milwaukee Bridge Co., Milwaukee, Wis., west end High Street, Mt. Vernon, $9,625; Jackson Ford, Morris Township, $2,075; Brackit Bridge Co., Cincinnati, O., $9,426, $2,088; King Bridge Co., Cleveland, O., $9,957, $2,233; Youngstown Bridge Co., Youngstown, O., $9,600, $2,125; Variety Iron Works, Cleveland, O., $9,763, $2,100; Vermont Construction Co., St. Albans, Vt., $9,750, $2,150; Chicago Bridge Co., Chicago, Ill., $9,670, $2,120; Columbus Bridge Co., Columbus, O., $9,900; Penn Bridge Co., Beaver Falls, Pa., $9,900, $2,250; Mt. Vernon Bridge Co., Mt. Vernon, O., $9,550, $2,050; Queen City Bridge Co., Cincinnati, O., $9,933, $2,400; Berlin Iron Bridge Co., East Berlin, Conn., $9,673, $2,063; Lane Bridge Works, Chicago, Ill., $9,700, $2,200; Massillon Bridge Co., Massillon, O., $9,973, $2,180; Wrought Iron Bridge Co., Canton, O., $9,700, $2,100; Missouri Valley Bridge Co., Attica, Ind., $9,773, $2,000.

Hackensack, N. J.—The Board of Freeholders of Bergen County have ordered a new bridge built across the Passaic River at Paterson and the rebuilding of another. The building of several other bridges in the county is under consideration.

Brooklyn, N. Y.—The Board of Supervisors on July 3 awarded the contract for the construction of the Meeker Avenue bridge to the King Iron Bridge Company, Cleveland (the lowest bidders), at $25,250.

Salinas City, Cal.—The following bids for the construction of a bridge over the Carmelo River, were received by T. J. Riodan, County Clerk, July 1: San Francisco Bridge Co., San Francisco, Cal., $7,400; Pacific Bridge Co., San Francisco, Cal., two bids, $8,565 and $9,195; Healey, Tibbett & Co., San Francisco., Cal., three bids, $8,092, $8,200, $6,995; King Iron Bridge Co., Cleveland, Ohio, four bids, $7,040, $6,330, $4,870, $3,400; Randell, Hunt & Co., San Francisco, Cal., four bids, $8,171, $8,620, $8,808, $9,180; San Jose Imp. Co., San Jose, Cal., two bids, $8,160, $6,675.

There is a project on hand to build a railroad bridge across Behring Strait.

Bridges.—See our Proposal Columns for information regarding bridge construction at the following places: St. Louis, Mo.; Boston, Mass.; Wheeling, W. Va.; Marietta, Ga.

The Contracting News Department of **THE ENGINEERING AND BUILDING RECORD** is edited with a view of giving space to no item that does not indicate where professional services or supplies may be needed in the near future, the prices bid for work or supplies, and the correction of false or misleading reports in some papers, that may subject readers to needless trouble and expense in going after something that does not exist.

STREET-WORK AND PAVING.

Utica, N. Y.—The contract to pave Gilbert Street with Sicilian rock asphalt was awarded to Patrick Griffin for $2.25 per yard.

Trenton, N. J.—The controversy in regard to paying for the Olden Avenue bridge in this city has been ended by the Board of Freeholders voting to issue $60,000 of county bonds to meet the claim.

Brooklyn, N. Y.—The following bids for paving Hamburg Avenue with cobblestone pavement, were opened July 3 by John P. Adams: Thomas McDonald, per running foot, $3.27; Henry Mogk, per running foot, $3.19; Dennis Norton, per running foot, $2.70; John Hickey, per running foot, $2.65.

New Brunswick, N. J.—The City Council of this place has voted to invite bids for macadamizing Hamilton Street.

Omaha, Neb.—Petitions have been presented to the Common Council of this place for paving a large number of streets.

Memphis, Tenn.—Several streets have been ordered paved in this city. J. G. Fogarty has been given the contract for paving Manassas Street at the following figures: Tishomingo gravel, 59½ cents per yard; grading, 25 cents per yard; guttering, $1.69½ per yard.

Davenport, Iowa.—The City Council of this place has adopted a resolution reciting that the streets of this city, especially such as have thereon street railway tracks, are in unusually bad order and can be readily put into passable condition, and giving the Street Committee general directions "to at once better the condition of such streets." There are also a number of specific improvements ordered.

Brooklyn, N. Y.—The following bids for paving various streets with granite blocks, were opened July 2 by John P. Adams Commissioner City Works: Charles Hart, per square yard, $2.50; improvement, linear feet, 18c.; new curb, linear feet, 50c.; new bridge, square feet, granite, 75c.; new bridge, square feet, cobble, 50c.; reflagging, square feet, 4c.; widening Warren Street, per running foot, 60c.; widening Water Street, per running foot, 60c.

William Kelly, per square yard, $2.49; improvement, linear feet, 18c.; new curb, linear feet, 45c.; new bridge, square feet, granite, 70c.; new bridge, square feet, cobble, 45c.; reflagging, square feet, 3c.; widening Warren Street, per running foot, 55c.; widening Water Street, per running foot, 55c.

Thomas Monahan, per square yard, $2.47; improvement, linear feet, 15c.; new curb, linear feet, 45c.; new bridge, square feet, granite, 73c.; new bridge, square feet, cobble, 43c.; reflagging, square feet, 3c.; widening Warren Street, per running foot, 45c.; widening Water Street, per running foot, 45c.

John H. O'Rourke, per square yard, $2.39; improvement, linear feet, 33c.; new curb, linear feet, 55c.; new bridge, square feet, granite, 70c.; new bridge, square feet, cobble, 50c.; reflagging, square feet, 5c.; widening Warren Street, per running foot, 35c.; widening Water Street, per running foot, 50c.

Toledo, O.—The following bids were opened at the engineer's office. The lowest bidder on Bancroft Street paving, from Ashland Avenue to Cherry, is on the Medina stone, Medina curb, H. P. Streicher, $36,415.50; Berea curb, $35,692.50; the same bidder is lowest on cedar block, $20,768, and fire brick, $28,628.02. On asphalt the Warren Scharf Co. is lowest, being $42,133.10. On Bancroft, from Monroe to Ashland Avenue, the Warren Scharf Co. bids, asphalt, $51,621.50; Medina stone, Claflin & Miller, $45,583.19; fire brick, H. P. Streicher, $36,213.15; cedar block, same, $27,227.15; Page Street, turnpiking, Leith Bros., $212.70; Monroe Street, grading, M. M. Goulden, $47.49; French Street, turnpiking, M. T. Ryan, $135; Ash Street, paving, Claflin & Miller, $265; Woodville Street, planking, Leith Bros., $5,528.42; Mulberry Street, boulder, Miller, $843.38; macadam, Ryan, $586.85; Parkwood, Medina curb, cedar block paving, H. P. Streicher, $4,029.24; Berea curb, Wm. McMahon, $3,877.46.

Norfolk, Va.—The following bids for furnishing 3,000 tons (2,000 pounds), more or less, of second-class granite paving blocks, were received by Adam Tredwell, Chairman Board of Street Commissioners, June 25: Greystone Granite and Construction Co., Greystone, N. C., $3.85 per ton; P Linehan, Raleigh, N. C., $3.94 per ton; Winnsboro Granite Co., Charleston, S. C., $7.15 per ton. Contract awarded Greystone Granite and Construction Co.

Amsterdam, N. Y.—The following bids for the construction of about 3,000 yards of brick pavement on concrete foundation were received by F. E. Crane, City Engineer: John C. Miller, $2.49½ per square yard; Hotaling & Brate, $2.50 per square yard. The contract was awarded to John C. Miller.

DES MOINES, IOWA.—Contracts for paving in this city have been let as follows: J. B. McGorrisk, paving with brick, Grand Avenue, $1.49; Fourth Street, $1.50; Fourteanth Street, $1.50; Fifteenth Street, $1.51. Cement curbing, King & Kennedy, 45½ cents; Fred Stehm, 46½ cents. Extra grading, J. A. Bryan, at 19 cents per yard.

PINE BLUFF, ARK.—There is a project on hand to pave certain streets at this place with vitrified brick.

FLUSHING, L. I.—The question of bonding this place in the sum of $40,000 for the purpose of paving the streets with macadam is being discussed by the Board of Trustees. Particulars can be had by addressing Judge Clinton B. Smith, Village Clerk, as above.

RAILROADS, CANALS, ETC.

ALBANY, N. Y.—The following bids for doing work on certain State canals were received by Edward Hannan, Superintendent of Public Works, July 8:

FOR LENGTHENING LOCKS ON ERIE, OSWEGO AND BLACK RIVER CANALS.

For Fultonville Bridge. — Substructure: Joseph P. Montz, Sandy Hill, $4,037.25; Flood & Sherrill, Sandy Hill, $3,701.75; Shanahan Bros. & Co., Tribes Hill, $3,760.25; Isaac Thomas, Fultonville, $3,532.25; P. J. McCaffrey, Utica, $4,955.25; Hughes Bros., Syracuse, $4,298.75. Superstructure: Rochester Bridge Works, Rochester, $4,359; Groton Bridge Manufacturing Co., Groton, $5,468; W. H. Shepard & Sons, Havana, $5,410; King Iron Bridge Co., Cleveland, O., $4,600.

Dredging Round Shoals.—E. M. Payne, Albany, 29 3/10c.; P. J. Brummelkamp, Syracuse, 13c.; P. W. Myers, Albany, 16¾c.

Dredging Van Buren Bar.—E. M. Payne, Albany, 31⅜c.; P. J. Brummelkamp, Syracuse, 20c.; P. W. Myers, Albany, 17c.

Machinery for Locks Nos. 40, 41, 42 and 43, Erie Canal.—N. and W. H. Wemple, Fultonville, $1,100 per lock.

THE Pottstown Passenger Railway Company of this city has been chartered, with a capital of $18,000. The company will construct a railway the entire length of High Street, a distance of nearly three miles. The officers are George N. Malsberger, President; Calvin Fegely, Secretary; William S. Ellis, Livingston Taylor, J. Allen Healy, Jacob C. Sotter and George N. Malsberger. It is understood that the company will build an electric railway.

BROOKLYN, N. Y.—It is reported that a syndicate has been formed to build a cable road in this city through Montague Street from Wall Street ferry to Court Street, and that work will begin at once. The men named as interested in the scheme are William H. Male, Henry J. Cullen, E. G. Blackford, ex-Assemblyman Hotchkiss, R. A. C. Smith and George H. Prentice.

THE Chicago and St. Louis Railway has been incorporated; capital, $3,000,000. The company will build a line between Chicago and East St. Louis.

NEWARK, N. J.—The Passaic River Extension Railroad Co. has been incorporated, with a capital of $20,000. The object of the company is to construct an extension of the Manufacturers' Extension Railroad to a point in the line of the Newark and New York Railroad branch of the Jersey Central Railroad.

STROUDSBURG, PA. — The Pennsylvania Mutual Railroad Company has been incorporated; capital, $3,000,000. The company will construct a road through Monroe and Lackawanna Counties, a distance of 50 miles. The line will be opened at the Delaware River near this city.

MADISON, WIS.—The North Wisconsin and Lake Superior Company has been incorporated. It is organized with a capital of $2,500,000 for the purpose of building a line of road from Oshkosh to Keweenaw Bay, Barago County, Mich. The length of the road is to be 200 miles. The incorporators are George Beyer, O. A. Ellis, W. P. Cook, W. H. Young, W. K. Smith, E. G. Murden and F. F. Wheeler, all of Oconto.

The Menominee River, Oconto and Southern has also been organized. It proposes to build a line 65 miles long from Marinette to a junction with the above mentioned road at Seymour, Wis. The capital is $750,000. The incorporators are identical with those of the North Wisconsin and Lake Superior.

ASBURY PARK, N. J.—The Ocean Grove and Shark River R. R. Co. has been incorporated; capital, $75,000. The company will construct a two mile street railway from Main Street and Cookman Avenue to the Public Road from Asbury Park to Belmar. The incorporators are Howard L. Chandler, of Philadelphia; W. L. G. Thomas, of Wilmington; James Middledith, of Plainfield; Edward M. Fielder, of Ocean Grove, and others.

DULUTH, MINN.—It is reported that the Duluth and Iron Range will build a branch from Tower to sections 10, 9 and 8, township 62, range 14, in which they have very valuable iron properties. The road will start at Soudan and skirt Stuntz and Armstrong Bays.

AUGUSTA, GA.—The City Council of this place has authorized the substitution of electricity for horses on the Augusta and Louisville Railroad lines.

ELECTRIC RAILWAYS.—New electric railways will be established and improvements will be made to those already built at the following places: Youngstown, O.; Troy, N. Y.; Saratoga, N. Y.; Williamsport, Pa.; Ottawa, Can.; Boston, Mass.; Albia, N. Y.; Grand Rapids, Mich.

GAS AND ELECTRIC-LIGHTING.

DAVENPORT, IA.—The City Council of this place has directed its Committee on Light to advertise for "the most practicable and cheapest plan to light the city with arc lights, and to offer a premium of $100 for the best and $50 for the next best plan received.

CHICAGO, ILL.—A press report in regard to natural gas for this city says, that contracts have been let for laying the pipe through Indiana, and that the work will be done by November 1.

PITTSBURG, PA.—It is reported that the stockholders of the Westinghouse Electric Company have voted to transfer their stock to the Westinghouse Electric and Manufacturing Company, and that the stock of the latter company has been increased from $5,000,000 to $10,000,000.

BIDS OPENED.

ALBERT LEA, MINN.—The bids for the building of the Albert Lea Lutheran High School have been opened, but were so much higher than the estimates of the architect that none were accepted.

NEW YORK CITY.—Bids were opened by the Department of Docks July 9, for building wooden pier, with appurtenances, including sewer boxes and a dumping board at the foot of East 110th Street: W. W. Hegeman, class 1, for pier, $24,400; class 2, for dumping board, $3,700; Terron & Jenks, class 1, for pier, $31,440; class 2, for dumping board, $5,500; J. Gielier, class 1, for pier, $27,300; class 2, for dumping board, $2,400.

MILWAUKEE, WIS.—The following bids for constructing a tunnel 3,000 feet long were received June 30, as follows: Shailer & Schinglau, Chicago, Ill., $121,643; W. Forristal, $128,667.50; J. O'Neill, $132,876; Thomas R. Bentley, $141,989; John J. Crilley, $191,200. The contract was awarded to Shailer & Schinglau. The contract for the crib was awarded to John O'Neill, for $34,000. The other bidders were: C. H. Sharke, $38,000; William Forristal, $34,500; Shailer & Schinglau, $40,000.

MINNEAPOLIS, MINN.—The contract for the superstructure of the Y. M. C. A. building has been let to James Carlisle & Sons, for $79,884.

WATERBURY, CONN.—The bids for erecting the new Bank Street school house were as follows: Carpenter work, Henry A. Lawlor, $22,490; Tracy Bros., $15,675; Charles O'Connor, $16,150; William M. Hurlburt, $17,729. Mason work, A. I. & G. S. Chatfield, $26,055; James F. Gaffney, $25,900; John W. Gaffney, $30,250; Patrick Thompson, $28,000. H. A. Lawlor bid for the whole contract $50,350, James F. Gaffney, $42,430, Patrick Thompson, $50,500. The contracts have been awarded to Tracy Bros. and James F. Gaffney.

ZANESVILLE, O.—Rocket & Sons have received the contract for heating by hot water the residence of Henry Werner.

MILWAUKEE, WIS.—The Board of Public Works have awarded to Messrs. Rundle, Spence & Co. the contract for furnishing 1,000 feet of iron pipe at 20½ cents per foot.

THE Editor of THE ENGINEERING AND BUILDING RECORD is always glad to receive items of news for the Contracting News Department. But such items are not considered news except when the prices and particulars of the award of a contract **are** given.

The announcement that —— has sold —— to —— without giving the *prices* and particulars concerns only the buyer and seller. Such notices are always excluded, except in the case where a certain firm is stated to have taken a certain contract, the execution of which would require that they should buy certain materials. Such an item would be used if deemed of more than local interest, because it would suggest to some readers the possibility of their making a sale or securing a subcontract.

GOVERNMENT WORK.

WASHINGTON, D. C.—The following proposals for furnishing and delivering iron girders and beams were received June 20: A. & P. Roberts & Co., Philadelphia, riveted trussed girders, per pound, 3.55c.; riveted plate girders, per pound, 3.55c.; connected beams, per pound, 3.55c.; Dearborn Foundry Co., Chicago, Ill., 3.65c., 3.3c., 3.8c.; New Jersey Steel and Iron Co., Trenton, N. J., 3.31c., 3.23c., 3.45c.; Pottsville Iron and Steel Co., Pottsville, Pa., 3.15c., 3.15c., 3.38c.; Carnegie, Phipps & Co. Limited, Pittsburg, Pa., 3.45c., 3.18c., 3.45c.; King Iron Bridge and M'f'g Co., Cleveland, O., 3.25c., 3.25c.; The Phœnix Iron Co., Philadelphia, Pa., 3.19c., 3.15c., 3.45c.; John M. Cornell, New York, N. Y., 3.8c., 3.4c., 3.4c. The contract was awarded to The Phœnix Iron Co.

EVANSVILLE, IND.—Charles Pearce & Co., of Indiana, have been awarded the contract, at $79,660, for the construction of the U. S. Marine Hospital Building.

DETROIT, MICH.—Patrick Dee was the lowest bidder for the construction of the basement and area walls of the new U. S. Court House and Post Office building. His bid was $111,573.

BROOKLYN, N. Y.—The following bids for dredging work at the Navy Yard were received at this city at the Navy Department: W. H. Beard, $20,700; P. S. Ross, Jersey City, $23,850; Atlantic Dredging Company, $21,600. Mr. Beard's bid being the lowest, his bid has been accepted.

WASHINGTON, D. C.—The following proposals for furnishing and delivering rolled iron beams were received June 20 by Bernard R. Green, Superintendent: A. & P. Roberts & Co., 3.45c. per pound; J. M. Cornell, 3.39c.; Pottsville Iron and Steel Company, 3.45c.; New Jersey Steel and Iron Company, 3.42c.; Carnegie, Phipps & Co., 3.45c., beveled ends; 3.15c., square ends; 2.25c., angles; Phœnix Iron Company, 3.45c., beveled ends; 3.15c., square ends; 2.05c., angles. The contract was awarded to John M. Cornell.

NEW CORPORATIONS.

THE A. J. McDonald Manufacturing Company at Chicago, to manufacture railway safety gates; capital stock, $50,000. Incorporators: A. J. McDonald, O. S. Dickson and Isaac T. Dyer.

THE Naperville Stone Company at Naperville, Ill., to quarry stone; capital stock, $50,000. Incorporators: B. B. Bocker, Alvin Scott, Jr., and H. H. Goodrich.

THE Electro Speaking Tube Construction Company at Chicago, to manufacture electrical goods, introduce speaking tubes, etc.; capital stock, $80,000. Incorporators: E. T. Orne, Warren Oral and Richard Robins.

SPRINGFIELD, ILL.—The following articles of incorporation were taken out July 7: United States Filter Manufacturing Company, Chicago; to manufacture filters; capital stock, $100,000; incorporators, Herman Vollmer, Horace L. Brand, William H. Bullen. Cyclone Crusher Company, Chicago; to manufacture mining machinery; capital, $200,000; incorporators, Henry W. Hinsdale, Henry Colberg, Horace J. Clark. Pan-American Engineering and Construction Company, Chicago; to promote engineering and agricultural works and projects; capital, $500,000; incorporators, William A. Stiles, Harry B. Waterman, I. J. Gill. Grand Marais Copper Mining Company; to mine minerals; capital, $2,000,000; incorporators, Phillip D. Armour, Jr., Henry P. Darlington, and Alfred R. Crion.

SPRINGFIELD, ILL.—Columbia White Lead Company, Chicago, to manufacture white lead, paints and colors; capital, $1,000,000; incorporators, James Warner Middleton, Milton A. Fair, William Brace.

Mississippi Valley Development Company, East Cape Girardeau, to operate water-works and electric light plants, for construction and operation of tramways and horse power and dummy roads, and to do mining business; capital stock, $50,000; incorporators, George H. Crumb, Lawson H. Watts, Dennis W. Wilson Copeland.

MIDDLETOWN, N. Y.—The Middletown and Port Jervis Bluestone Company has been incorporated, with a capital of $50,000. The company's quarries are at Oakland, Sullivan County.

INDUSTRIAL.

SYRACUSE, N. Y.—The Pierce, Butler & Pierce Manufacturing Company, Steam and Mechanical Engineers and Contractors, 118 Clinton Street, Syracuse, N. Y. (main office), has opened offices at New York City, 60 Barclay Street, and at Boston, 237 Franklin Street; Chicago, 96 Lake Street.

SAN FRANCISCO, CAL.—The new City Hall Commissioners, at a meeting held July 4, authorized the secretary to advertise for bids for building the city prison; also for cement stone pavements and granite curbs around the City Hall reservation.

SPARTA, MICH.—At a meeting held on July 7, to vote on the question of bonding the village for $4,000 for a public building, 127 votes were cast in favor of, and 5 against, the proposed building.

PROPOSALS.

(Continued from page x.)

CITY OF NEW BRUNSWICK, N. J.

Notice to Contractors.

SEALED PROPOSALS WILL BE RECEIVED by the undersigned, Clerk of the Common Council of the City of New Brunswick, N. J., until 12 o'clock noon, WEDNESDAY, July 23, 1890, for laying a 12-inch **MACADAMIZED PAVEMENT** on Livingston Avenue, in said city, from George Street to Comstock Street (about 20,000 square yards of pavement). The work to be done under the authority of and in conformity with Chapter No. 148 of the Public Laws of the State of New Jersey, passed 1889.

All bids must be made upon the blank forms furnished by the City Surveyor, at whose office, No. 1 Paterson Block, the form of contract and specifications may be seen, and other necessary information as to excavation, etc., obtained.

The Common Council reserves the right to reject any or all bids.

H. B. COOK, City Clerk.

New Brunswick, N. J., July 3, 1980.

Notice to Sewer Contractors.

GLOVERSVILLE, N. Y., June 26, 1890.

SEALED PROPOSALS FOR THE CONstruction of **SEWER EXTENSIONS** and sewer appurtenances, and for furnishing material for the same in the CITY OF GLOVERSVILLE, N. Y., will be received at the office of the City Clerk, and shall be addressed to Chairman of Committee on Sewers, and marked "Bids for Sewer Extensions."

No bids will be received after 6 o'clock P. M. July 21, 1890.

The work will comprise in general the following quantities:

10-inch vitrified pipe, about	1,050 feet.
8 " " " "	7,290 "
6 " " " "	1,750 "
4 " " " "	4,800 "
Manholes .... "	26
Lampholes .... "	33

Every proposal shall be signed by the bidder, and accompanied by cash or a certified check to the amount of two hundred dollars ($200), made payable to the City Chamberlain of the City of Gloversville, N. Y., conditioned upon the execution of the required contract and required bond for the faithful performance of the terms of the contract in case of award. The checks of unsuccessful bidders will be returned to them immediately after the contract is awarded or all bids are rejected.

Specifications can be had on application to F. H. WILMARTH, City Clerk. Plans can be seen at the office of the City Engineer.

The Common Council reserves the right to reject any or all bids.

EUGENE MEAD,
Chairman Committee on Sewers.
F. E. ABBOTT,
City Engineer. 6

JULY 10, 1890.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M. on the 6th day of August, 1890, for all the **LABOR AND MATERIALS** required in the erection and completion of the U. S. Post-Office building at LOWELL, MASS., (approaches and heating apparatus not included) in accordance with the drawings and specification copies of which may be had on application at this office or the office of the Superintendent. Each bid must be accompanied by a certified check for $500. The Department will reject all bids received after the time fixed for opening the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be sealed and indorsed "Proposals for the Erection and Completion (except Heating Apparatus and Approaches) of the U. S. Post-Office building at Lowell, Mass.," and addressed to JAS. H. WINDRIM, Supervising Architect. 7

JUNE 28, 1890.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M. on the 23d day of July, 1890, for the Iron Stairways and **IRON WORK** of Interior Finish for the U. S. Court-House and Post-Office building at PITTSBURG, PA., in accordance with drawings and specification, copies of which may be had on application at this office or the office of the Superintendent. Each bid must be accompanied by a certified check for $300. The Department will reject all bids received after the time fixed for opening the same; also, all bids which do not comply strictly with the requirements of this invitation. Proposals must be sealed and indorsed "Proposal for Iron Stairways and Iron Work of Interior Finish for the U. S. Court-House and Post-Office building at Pittsburg, Pa.," and addressed to JAS. H. WINDRIM, Supervising Architect. 6

PROPOSALS FOR MILITARY SUPPLIES. Office of the Quartermaster, U. S. Military Academy, West Point, N. Y., July 9, 1890. Sealed proposals, in duplicate, subject to the usual conditions, will be received at this office until 12 o'clock, noon, on the 8th day of August, 1890, for Gas Coal, Anthracite Coal, Hardwood, Charcoal, Building Materials, Paints, Plumbing Materials, Gas and Steam Fittings, Pulleys, Belting, Arch Plates for Steam Boilers, Fire Brick, Fire Clay, Stationery, Printing Materials, Office Furniture, Brooms, Soap, Brushes, Range Parts, and other miscellaneous stores specified on schedules to be had upon application here. Preference will be given to articles of domestic production or manufacture, conditions of quality and price (including in the price of foreign productions or manufactures the duty thereon) being equal. Inclose proposals in envelope marked "Proposals for Military Supplies," and addressed to the undersigned, CHAS. W. WILLIAMS, Captain and A. Q. M., U. S. A. 9

PROPOSALS.

PROPOSALS FOR PLUMBING, ETC.— Depot Quartermaster's Office, David's Island, N. Y. H., July 1, 1890.—Sealed proposals, in triplicate, will be received until 11.30 A. M., WEDNESDAY, July 30, 1890, and opened immediately thereafter, for supplying and fitting up **BATH-TUBS, WATER-CLOSETS** and **URINALS** in basement of 1888 Brick Barrack at this place. Plans, specifications, general instructions to bidders and blank forms of proposals will be furnished to bidders on application to this office. The right to reject any or all bids is reserved to the United States. Captain J. McE. HYDE, Assistant Quartermaster, U. S. Army, Depot Quartermaster. 8

PROPOSALS FOR SERVICE CONNECtions.—Office of Post Quartermaster, Fort Keogh, Mont., July 5, 1890. Sealed proposals in triplicate, subject to the usual conditions, will be received at this office until 12 o'clock noon, on the 5th day of August, 1890, and then opened, for furnishing all the labor required in making **SERVICE CONNECTIONS** with water mains at this post. Specifications, instructions to bidders, and blank forms of proposals will be furnished on application to this office. M. C. MARTIN, 1st Lieut. & R. Q. M. 22d Infantry; A. A. Q. M., U. S. A. 9

NOTICE TO BIDDERS.

SEALED PROPOSALS ADDRESSED TO the Board of Public Works, MUSKEGON, MICH., will be received up to 5 o'clock P. M. MONDAY, the 21st day of July, 1890, for furnishing materials and labor, and constructing the following works:

A. An inlet crib, a 30-inch inlet pipe, about 3,600 feet long and a 24-inch inlet pipe, about 750 feet long, in and under Lake Michigan, together with their connections.

B. Constructing shore receiving wells.

C. Grading about the pumping station and constructing docks.

D. Furnishing and erecting pumping engines, boilers, their appurtenances and connections.

E. Constructing a pumping station and suction pipe tunnel.

F. Furnishing about 2,300 feet 24-inch, 5,000 feet 16-inch, 800 feet 6-inch, iron pipe with special castings.

G. Furnishing valves and hydrants.

H. Laying pipes and setting valves and hydrants.

Proposals will be received for doing the whole or any part of the above work, and the right is reserved to reject any or all of them.

Accompanying each bid, must be a certified check payable to the city of Muskegon, Mich., as a guarantee to be forfeited if the bidder fails to enter into and complete the contract awarded to him; the amount to be $500 except for the bid on the lake work, in which case it will be $2,500.

Plans and specifications may be seen at the office of the Board of Public Works, Muskegon, or of the Engineer.

By order of the Board of Public Works.

A. V. MANN,
Prest. B. of P. Works.
CHESTER B. DAVIS, Engineer,
Rookery Building, Chicago, Ill.

SEWERS, Albany, N. Y.—Proposals are wanted, no date specified, for laying vitrified stoneware pipe sewers in certain streets at this place. Address the Street Commissioner, as above.

Cranston and High sts, bus block; cost, $30,000; o, C E Souther and others; b, Whitaker & Smith.

Broadway, 2 fr dwells; cost, $8,000, o, Jane and Isabella Dewsnap; a, John Davidson.

Potters av, bus block; cost, $20,000; o, Hearn & Braikch; a, Geo W Cady; b, N B Horton.

POTTSVILLE, PA.—Pike st, Pt Carbon, remodeling; cost, $8,700; o, Robt Allison; a, W D Hill; b, D Gellinger.

760 Mahntongo, remodeling; cost, $7,500; o, G J Wadlinger; a, Bertolet; b, Sailor.

SALT LAKE CITY, UTAH.—12th, East and 3d sts, 2-story br dwell; cost, $8,000; o, Chas Baldwin; a, W E Ware.

SIOUX FALLS, S. D.—Architect W L Dow has prepared plans for the erection of a $25,000 bank and office building at this place.

SPRINGFIELD, O.—Nothing over $7,000 in value to report.

ST. LOUIS, MO.—Bell and Vandeventer avs; br dwell; cost, $11,000; o, I De Figuaredo and others; b, Goesse & Remmerse.

Lewis Park and Taylor av, br dwell; cost, $7,000; o, Dr Whipple; b, W E Clayton.

Bell and Grand avs, br dwell; cost, $17,000; o and b, J Bizant.

12th st and Clark av, br city hall; cost, $1,150,000; o, City of St Louis; a, Eckel & Mann; b, sub-let.

S w cor 4th and Morgan sts, br store; cost, $30,000; o, Jno Meier; b, sub-let.

The contract for the foundation, excavation and pile driving for the new City Hall in this city has been awarded to W F Hopkins, at $79,732.

ST. PAUL, MINN.—Rice nr Front, 2 story br dwell; cost, $7,000; o, Frank Heines.

Dayton nr Kent, 2-story br dwell; cost, $8,000; o, J W Miller.

Mound nr Thorn 2-story br dwell; cost, $28,000; o, J F Eisinmenger.

Iglehart nr Mackubin, 2 2-story s dwells; cost, $16,000; o, Deeks & Witbeck.

12th nr Cedar, 2-story br dwell; cost, $10,000; o, J A Berkey.

Victoria nr Dayton, 2-story br dwell; cost, $10,000; o, A S Phinney.

SALT LAKE CITY, UTAH.—6 West st, 2 story br warehouse; cost, $40,000; a, Carroll & Kern.

TOPEKA, KAN.—Nothing over $7,000 in value to report.

WORCESTER, MASS.—Br factory for envelopes; cost, $15,000; o, W H Hill; a, Fuller & Delano.

Cambridge, br factory for carpets; cost, $20,000; o, Chas Compton; a, same as above; b, J G Vandrencil.

Wachusett, fr dwell; cost, $7,000; o, F E Williamson; a, Barker & Nourse; b, not let.

BUILDING INTELLIGENCE.

WASHINGTON, D. C.—1341–43 F st, 2 br dwells; cost, $8,000; o and b, Jos Robbins.

2231–41 I st, 6 br dwells; cost, $40,000; o, Albert Gleason; a, O Von Nerta; b, Bright, Humphreys & Co.

2021 H st, br dwell; cost, $10,500; o, A R S Foote; a, A B Bibb; b, Alex Miller.

1501 11th st, br dwell; cost $8,000; o and b, Robt L Warring; a, B S Simmons.

1219 16th st, 3-story br bldg; cost, $18,000; o, T O Evans; a, Chas E Emonston.

1333 R I av, 3-story br bldg; cost, $7,000; o, J Tourney; a, Louis Leibhart.

607–11 Mass av, 3 2-story br bldgs; cost, $10,500; o, Carrier & Koman.

1114 14th st, 3-story br bldg; cost, $12,000; o, A K Humphrey; a, R I Fleming; b, C C Martin.

1423–37 W st, 7 2-story br bldgs; cost, $30,000; o, A T Varnell; a, W L Conley; b, Ward & Co.

1702 16th st, 3-story br bldg; cost, $9,000; o, M N Shafer; a, Jos B Williamson.

1815–19 14th st, 3 2-story br bldgs; cost, $7,000; o and a, Rorse & Baker.

307–19 F st, 7 2-story br bldgs; cost, $7,000; o, C F Smithson; a, P N Dwyer; b, C F Evenston.

825–27–29 C st, 3 2-story bldgs; o, Mary Atkins; a, Jos Johnson; b, O Donnelly.

2418–20 K st, 2 2–story br bldgs; cost, $7,000; o and b, J H Grant; a, N R Grimm.

2d, bet D and E sts, 9 2–story br bldgs; cost, $26,000; o, A J Fisher; a, as above.

920 Massachusetts av, 3-story br bldg; cost, $10,000; o, W B Downing; a, as above.

Water, bet 32d and 33d sts, 3-story br bldg; cost, $14,000; o, Weaver Kingla & Co; a, as above.

1417 G st, 3-story br bldg; cost, $16,000; o, I S Kimball; a, C C Martin.

923–25–27 20th st, 3 2-story br bldgs; cost, $10,000; o, A P Fardon; a, as above.

Trinidad av, 13 2-story br bldgs; cost, $7,800; o, E E Ramy; a, G R Arrington.

Florida av, 10 2-story br bldgs; cost, $25,000; o, G S Wormley; a, C S Bunt.

N Capitol and N st, 5 2–story br bldgs; cost, $15,000; o, Ed Waltz; a, as above.

1436 to 42 V st, 4 2–story br bldgs; cost, $7,500; o, Theo Frebus; a, Gus Frebus; b, E T Jones.

247 permits less than $7,000 in value.

1228 22d st, 4 story br bldg; cost, $15,000; o, W B Moses & Son; a, Jno H Howlett.

1626 Rhode Island av, 3-story br bldg; cost, $45,000; o, A C Barney; a, Barry, Simpson & Andrews; b, C A Langley.

2023 H st, 3-story br bldg; cost, $8,000; o, Jos Hunter; a, Jos H Byram.

804–8 6th st, 3 2-story br bldgs; cost, $7,000; o and b, J F Cullinan; a, P N Dwyer.

1525 P st, 3-story br bldg; cost, $9,700; o and a, J R Brooks.

Pennsylvania av bet 3d and 4th sts, 3-story br bldg; cost, $30,000; o, National Cap. Bank; a, A P Clark; b, Jas Parsons.

Wyoming av, 3-story br bldg; cost, $12,000; o, L M Saunders; a, R Stead; b, F Pelling.

1701 2d st, 3-story br bldg; cost, $75,000; o, G S Fraser; a, Hornblower & Marshall,

2123–29 L st, 4 2-story br bldgs; cost, $12,000; o and a, G Dearing.

1916 N st, 3-story br bldg; cost, $11,000; o, Wm Wall; a, T F Schneider; b, Emmet & Co.

Jackson and Pierce st, 3-story br bldg; cost, $12,000; o and b, W F Kirby; a, A P Clark.

WIKES BARRE, PA.—Nothing over $7,000 in value to report.

YONKERS, N. Y.—A $30,000 church will be erected here. Address Architect E A Quick, as above.

A brick and stone building will be erected here at a cost of $10,000. Address Architect E A Quick, as above.

A $12,000 building will be erected here. Address E A Quick, architect, as above.

YOUNGSTOWN, O.—Nothing over $7,000 in value to report.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22. NUMBER 7. | PUBLISHED EVERY SATURDAY. 277 PEARL ST., NEW YORK.

NEW YORK, JULY 19, 1890.
LONDON, AUGUST 2, 1890.

SINGLE COPIES, TEN CENTS. Subscription, $4.00 per year in advance, post paid. } IN AMERICA.
SINGLE COPIES SIXPENCE. Subscription, 20s. per annum in advance, post paid. } IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.
20*s*. in GREAT BRITAIN. Other Foreign Countries $5.
Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $5; China, Japan, Sandwich Islands, Mexico and Cuba, $5; South America, $5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

TABLE OF CONTENTS.

EDITORIALS:

THE VENTILATION OF STEAMSHIP FIREROOMS.

EXTRAORDINARILY high temperatures in steamship firerooms—going considerably beyond 100° Fahr.—have come to be looked upon so much as matters of course that they have apparently ceased to attract general attention, and little effort seems to be made by those in authority to bring about a better state of affairs. It is fair to say that the conditions under which the firemen work in the stoke-holes of some of the fast Atlantic steamers pass altogether beyond popular appreciation, the mere statement of temperatures, ranging from 120 to 140 degrees, affording no adequate measure of the suffering which these men go through.

On one of the latest steamers of an Atlantic coast line, a temperature of 138 degrees is said to have been recorded in the fireroom by a thermometer held directly underneath the ventilator. On another one 140 degrees are said to have been noted, and the average for a large number is placed at 125 degrees. During the summer time the heat of the tropics is sometimes added to that of the firerooms, making the conditions almost unendurable.

Short fireroom watches, with comparatively long intermissions,. seem to be about the only expedients which have been tried to any extent to relieve the hard-worked men. One notable exception is found in the new steamer Majestic, of the White Star Line, which is said to have such excellent arrangements for ventilating the fireroom that the temperature rarely rises above 105 degrees, and is often lower. The whole secret of the success in maintaining a fairly comfortable temperature in this case is found in the rational application of blowers, which have been put in, and could be used with equal success in other vessels, at comparatively trifling expense. Figures ranging from $500 to $600 have been given as the price of making life seem worth living, by these means, in the stoke-hole of almost any steamer, and these should commend themselves to the attention of those having the power to act. It has been well pointed out that, with the now available means of driving air about, there ought to be no difficulty in keeping up a mild tornado in every stoke-hole, and in subjecting a stoker to no more risk than a farm laborer is exposed to on a warm day in summer. It is to be hoped that the good example set in the case of the Majestic will not be without a generally beneficial influence. The problem to be solved is not a difficult one, and the question of expense is so trifling that it should scarcely call for consideration.

SMOKE NUISANCE IN WESTERN CITIES.

EVERY now and then the question of smoke prevention comes up for discussion in some of the larger western cities like Chicago, St. Louis and Cincinnati, and suggestions are offered designed to bring about an abatement of the smoke nuisance. Thus far, however, all the remedies proposed have proved ineffectual. Quite recently the subject was discussed at length by the Chicago Commercial Club, and the conclusion apparently was reached that the establishment of a large central plant for generating steam, like that of the New York Steam Company, would prove a satisfactory partial solution of the problem, since, after all, manufacturing establishments using steam for various purposes were responsible for a large portion of the smoke. The situation, briefly stated, was about this:

Each building in the manufacturing and business district has its own boiler and chimney belching forth unconsumed carbon. Each uses soft coal because it costs but about half of what anthracite costs. It is hopeless, it was held, to try to force the whole business community with the weak machinery of an ordinance and an irresolute administration to substitute an expensive for a cheap fuel. If the generation of steam were concentrated at a few points in great steam producing batteries; if instead of a large number of scattered boilers there were half a dozen batteries of boilers of from 10,000 to 20,000 horse-power, each generating steam and distributing it through pipes, the smoke nuisance would cease. Where the works were on so large a scale self-feeding furnaces could be profitably used. Small boilers could not stand the expense. The quantity of steam now used could be produced with about half the present amount of coal, and this saving would enable a company to sell steam much cheaper than people could produce it for themselves by the present methods.

All this sounds very well. As a matter of fact, however, high-pressure steam distribution in cities from central stations is not an unqualified success. The steam produced at such stations, as experience has well shown, is not sold at such low figures as seems to be taken for granted; and, finally, it is not likely that steam users would, or could, be forced to buy their steam supply from such steam companies. The solution of the difficulty is to be found simply in strengthening what has been characterized above as the weak machinery of an ordinance, specifying smoke prevention. If the smoke rules were made sufficiently stringent, and their enforcement looked after, ways and means to avert the evil would be forthcoming. Even if there were no attempt at enforcing the substitution of an expensive fuel for a cheap one good results might be attained.

Careless and unskillful firing lies at the root of much of the smoke evil. Conscientious management in fire-rooms and the adoption of rationally-designed furnaces—not one of the many quack devices with which the market is now flooded and for which all sorts of impossible things are claimed—would accomplish much in overcoming the constantly increasing smoke trouble. Central steam distribution, however, would not prove an unalloyed blessing, if indeed a blessing at all. Rather, if we may judge by New York's experience, it would be the greater nuisance.

STEAM AS A FIRE EXTINGUISHER.

THE use of steam as a means of extinguishing fire is not new, and its advantages in point of convenience and, for that matter, of efficiency over many other commonly practiced methods have frequently been given prominence. There have, however, been cases where the method has failed completely, and much damage and disappointment has resulted, leading eventually to serious questioning whether steam really deserved all the praises bestowed upon it as a fire extinguisher. It will, therefore, not be amiss to direct attention to the very important circumstance that the conditions essential to the success of the method are occasionally wholly ignored, and, in cases of failure to act efficiently, the causes are generally not difficult to find.

The prime requisite of success is that the space in which the fire is burning should be inclosed so that free access of air is cut off, and steam under pressure and in ample quantity can be let into the apartment. It must be borne in mind that the efficiency of the steam in extinguishing fire is due simply to the fact that the vapor displaces the air and, with it, the supporter of combustion, atmospheric oxygen. If this circumstance were given due thought there would be less disappointment and fewer heavy losses where steam jets are depended upon for fire protection. A few years ago, we believe, reports of experience in Germany with the steam jet method recorded decidedly unsatisfactory results, and inquiries were frequent as to the exact conditions under which it was practiced in mills in this country where it was known to have rendered excellent service. The whole secret of success, however, if such it can be called, is in the correct application of the simple principle we have stated.

OPENING OF THE NEW CROTON AQUEDUCT.

The new Croton Aqueduct began to discharge water into the Central Park reservoir, New York, at some time between 5 and 6 o'clock Tuesday morning, July 15, at the rate of about 40,000,000 gallons per day, which was afterward largely increased. There was no formal ceremony attending the opening of the gates at the One Hundred and Thirty-fifth Street gate-house, though the operation virtually marked the completion of one of the great engineering works of the age. It was generally expected that Mayor Grant would open the gates in the Central Park gate-house at about 2 o'clock in the afternoon, but there was a misunderstanding somewhere. As a matter of fact the Central Park reservoir gates have been opened for the last few months, and when Mayor Grant arrived he found the water from the new source already rushing out of the pipes.

The Central Park reservoir holds 1,000,000,000 gallons of water. The dividing wall of masonry which separates the east basin from the west will be three feet under the surface when this capacity is reached. That partition has not been out of sight since 1877.

On Wednesday there was a break at Shaft No. 24, just above the Harlem River, allowing a daily escape of water of about 250,000 gallons. This, however, will not seriously interfere with the filling of the reservoirs. When this has been accomplished the flow of water will be shut off and the necessary repairs carried out. The place where the break occurred was known to be weak, and was in any event to have been strengthened before permanent use.

There appears no reason to doubt that the aqueduct will furnish the supply as had been expected from this time on. The progress of work on the aqueduct for the five years occupied by it, as well as its engineering and construction features, have been fully described in this journal.

NEW YORK DEPARTMENT OF PUBLIC WORKS.

The report of Commissioner Gilroy, of the Department of Public Works of New York City, for the quarter ending June 30, shows that during the three months the rainfall in the Croton and Bronx watersheds was 12.9 inches and that no stored water was drawn, and that the Croton Aqueduct furnished a steady supply of 95,000,000 and the Bronx River conduit one of 18,000,000 gallons of water per day. Water mains were laid in new streets 37,321 feet, and 64 stop cocks and 103 fire hydrants were put in. There were 705 new water meters placed, making 21,053 in use in all.

There were 106,367 square yards of new granite block pavement laid on up-town streets and in replacing old pavement, with 1,500 yards of trap blocks and 11,206 yards of asphalt pavement. Work is now in progress on 13 repaving contracts, covering 456,000 square yards.

There were 7,256 excavations made in the streets by individuals and private corporations for laying and repairing gas and steam mains and electric subways. The total expenditures of the Department for the quarter were $1,189,563.

OCEAN STEAMER LANDING AT LIVERPOOL.

A plan is proposed by Joseph Boult, C. E., to enable passengers on ocean steamers to disembark at Liverpool without the inconvenience of going ashore on tenders or waiting for the vessel to get into its dock. The proposal, as summarized by the London *Architect*, is to form a new harbor at the extreme north end of the Liverpool dock estate by projecting a breakwater from a point near the Seaforth Battery to a point about 300 yards from the Canada entrance. The greatest width of the harbor inclosed by the breakwater would be 400 yards, while the entrance at the south end would be 250 yards wide. Inside the breakwater Mr. Boult would moor a pontoon stage of sufficient length for four steamers, each 600 feet long, to lie alongside. On the top of the breakwater he proposes that a railway shall run in connection with the London and Northwestern, the Midland and the Lancashire and Yorkshire lines, which run down to the docks. With the help of floating shields he would provide comparatively smooth water, even in stormy weather; while, if necessary, the present depth of 25 feet at low-water spring tides might be increased at moderate expense. Thus steamships could disembark their passengers at any state of the tide, and the passengers could, by means of floating roadways, reach the trains awaiting them at the breakwater, and the vessels, having landed passengers and mails, would be in good position for being taken into the Langton, Alexander, or other north docks, which are just behind the proposed new harbor.

THE VYRNWY AQUEDUCT UNDER THE WEAVER.

According to the *Journal of Gas Lighting* one of the heaviest undertakings in main laying ever accomplished is the line of pipe aqueduct from the Vyrnwy to Liverpool. This is ultimately to comprise a triple line of 42-inch pipe, but only one line is actually being laid, except at the Weaver crossing, where all three have been laid at one operation to save future interference with the channel. The river is crossed by three 32-inch riveted steel pipes ⅝-inch thick; the flange joints being made with an india rubber ring and a washer of seven pound milled lead, secured with 1¼-inch compressed fluid steel bolts. At the point where the mains cross the channel is 100 feet wide and 15 feet deep, and the pipes had to be laid at a depth of 21 feet. Accordingly a trench was excavated, chiefly by grabs worked by steam cranes on barges, and the ends sheet-piled so as to receive the ends of the pipes in little docks. The three lines of piping, 108 feet long, were connected together with collars and plates; and, in addition, a rectangular cast-iron frame was fastened near to each end for a temporary purpose to be presently described. The trench being ready and the pipes floated into position over it, their ends covered by temporary blank flanges, and slung by chains over four winches, water was admitted in sufficient quantity to slowly sink them into their final place. The process of sinking only occupied 15 minutes. The pipes being thus laid, the next step was to drive sheet piling against the temporary cast-iron frames already mentioned, cover the pipes with concrete, and generally make good the river bed and bank. The sheet piling thus kept out the water of the river, and enabled the little docks in which the ends of the pipes lay to be pumped clear for making the shore connections.

The faculty of the new architectural department of the University of Pennsylvania will consist of William Pepper, M. D., LL. D., Provost, *ex-officio* President; Horace Jayne, M. D., Dean; Theophilus P. Chandler, Jr., architect, Director; Thomas W. Richards, A. M., Professor of Architecture, and Charles E. Dana, Professor of Art. The architects who will be regular lecturers are: Theophilus P. Chandler, Jr., Frank Furness, Wilson Eyre, Jr., Frank Miles Day, Joseph M. Wilson, Addison Hutton, John Stewardson, and J. Barr Ferree.

The American Society of Swedish Engineers has been incorporated under the general incorporation law of New York, with Henry Sellman and Gustave P. Wern, Brooklyn; Arvid Sandgren, New York, and Gustaf Leonard Backstrom and Carl Sundstrom, Philadelphia, as trustees.

It is reported that enough money has been subscribed toward building the Paris ship canal so that the Government will probably sanction the scheme.

The London County Council has abandoned the bill providing for improving the Strand. The action followed the rejection by the Parliamentary Committee of the "betterment," or special assessment feature of the measure.

OBITUARY.

James Keary, contractor and builder, died in Jersey City, N. J., July 13. He built several of the larger Catholic churches in the city.

William B. Fitch died at Kingston, N. Y., July 14, aged 67 years. He was one of the pioneers in the bluestone business, in which he was engaged nearly all his working life.

General Silas Seymour died in New York City, Wednesday, aged 73 years. He was born in Saratoga County, N. Y., and gave nearly his whole life to civil engineering. He was professionally connected with the Erie Railroad and built for it the Portage bridge over the Genessee River. He was elected State Engineer of New York in 1855, and while in office had charge of the work of enlarging the Erie Canal. During the Civil War he aided in organizing the military railroad service. Having helped General Sickles organize the Excelsior Brigade, he served for a time on his staff. After completing the Washington aqueduct and building a railroad bridge across the Potomac at Washington, he became in 1864 consulting engineer of the Union Pacific Railroad and served as such until the completion of the road in 1869. After having professional connection with other railways, in Canada as well as this country, he was again elected State Engineer of New York in 1881. He continued to practice his profession until his death and was connected with a long list of important engineering structures.

Brigadier-General Daniel T. Van Buren died suddenly Thursday at his home in Plainfield, N. J., in the 65th year of his age. He was born in Kingston, N. Y., and graduated at the West Point Military Academy in 1847. He served in the army until after the Mexican war, was professor of natural and experimental philosophy at West Point for a short time, and was assigned to duty on the coast survey in 1852, where he remained until 1855 when he resigned, studied law and was admitted to the bar in his native village, and also practiced as a civil engineer. He was Colonel of Engineers in the National Guard from 1858 to 1866. At the beginning of the war of the rebellion he became attached to the Engineer Corps, Twentieth New York, and afterward was chief of staff of Major-General Dix, successively commanding the Department of Pennsylvania, Division of the Army of the Potomac, Middle Department at Baltimore, Seventh Army Corps at Fortress Monroe, and Department of the East. From July 16, 1865, to February 9, 1866, he served as Assistant Adjutant-General on the staff of Major-General Hooker, commanding the Department of the East. March 13, 1865, he received the brevet of Brigadier-General of the United States Volunteers for faithful and meritorious services during the rebellion. He was mustered out of the service March 20, 1886, and for a time was a surveyor and engineer at Kingston. Since then he has lived at Plainfield. General Van Buren had for some time suffered from heart trouble, which had been rendered more serious by the death of his son about a year ago, and finally caused his death.

PERSONAL.

W. S. Bacot has been appointed County Engineer of Richmond County, N. J.

Julius Fix has been appointed Engineer and Superintendent of the Water-Works at Stoughton, Wis.

H. H. Cloud has resigned his position as Chief Engineer of the Pecos Valley Railroad.

K. Emil Hilgard, M. Am. Soc. C. E., of Cincinnati, O., leaves for Europe next month, to be absent six months.

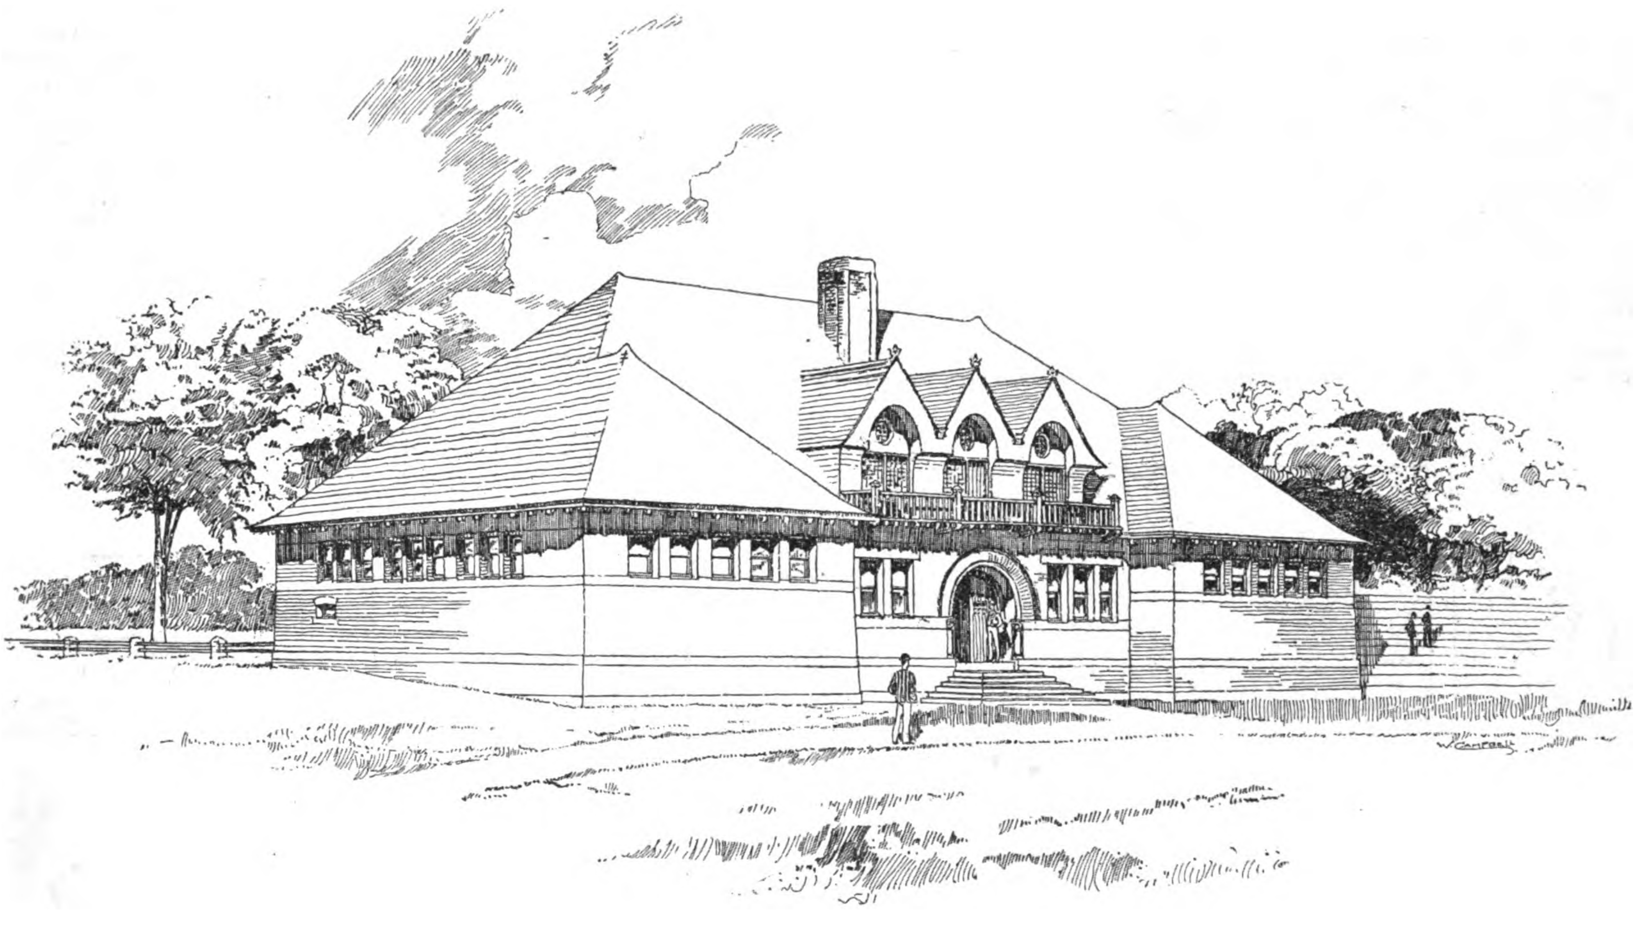
ENGINEERING SOCIETIES.

The Civil Engineers' Club of Cleveland held a meeting July 8, with President Searles in the chair, A. H. Porter Secretary, and 18 members and 3 visitors present. James Morris Wright was elected an active member.

Mr. Mordecai reported for the Committee on Affiliation of Engineering Societies that he had heard from Mr. Holloway, who had attended the meeting appointed in New York for conference, and that the attendance was very small and nothing was accomplished at that time.

The president read a letter from C. Kirchhoff, Jr., Secretary of the American Reception Committee, stating that, owing to a change in the programme, the party of foreign iron masters and engineers will not visit Cleveland, although some individuals may be able to do so.

The amendments to the constitution of the Association of Engineering Societies, proposed by the Board of Managers and published in the December number of the *Journal*, were presented for consideration. The first and second amendments were separately discussed and finally adopted.



CAREY ATHLETIC BUILDING, FOR HARVARD COLLEGE, CAMBRIDGE, MASS.—LONGFELLOW, ALDEN & HARLOW, ARCHITECTS, BOSTON, MASS.

The paper of the evening, on "Methods of Wall Decoration," was read by C. O Arey. After noting the objections to oil colors and calcimining process he narrated his experience with other methods. The encaustic process as practiced by the ancient Greeks was found too expensive. The fresco practiced in the early renaissance was found satisfactory, with the exception that the work was liable to be injured or broken after completion by the finishing carpenters. He then tried many experiments to find a method similar to this fresco which could be applied on a dry wall, and this was accomplished by a chemical union of alum and lime, providing only mineral colors were used. This method allows one to apply on the wall a permanent finish unaffected by water, at a very moderate expense. The paper was discussed by Messrs. Barber, Hermann, Richardson, Porter and others.

LETTER FROM ENGLAND.

London, July 4, 1889.

The committee appointed by the London County Council to go into the question of water supply and the charges of the water companies in connection with the metropolis had a further meeting yesterday. Allen Stoneham, auditor of the metropolitan water companies and Assistant Secretary to the Board of Trade, pointed out that a meter system, if adopted in the city, would result in a very considerable curtailment of the rates of the New River Company, and that the adoption of such a system would work disadvantageously in the poorer neighborhoods. The opinion of this witness is unquestionably worth serious consideration. It is evident that a landlord who is of the sweater persuasion will immediately bring pressure to bear upon his tenants should the meter system be adopted with a view to reducing the consumption, thereby prejudicing the cause of sanitation and cleanliness.

The proceedings in the inauguration of public baths at Newport, Monmouth, by the municipal authorities were certainly uncommon. The occasion was a public ceremony when the Mayor and corporation, in robes of office, attended and made speeches to a mixed audience of ladies and gentlemen. No sooner, however, had the Mayor made his speech than he, without waiting to listen to replies, and accompanied in a surreptitious manner by the members of his corporation, disappeared, only to return in the course of a few minutes lightly attired in a costume which was suggestive of the Turkish bath. When the speeches had been concluded, to the astonishment of the audience, his worship, the Mayor, took a dive into the baths, being followed by the members of the corporation, as also by the constables on duty, the latter not having the opportunity of divesting themselves of tunics, helmets, or clothing generally. The scene must have been a very funny one, and the Mayor of Newport is to be congratulated on making a spectacle that is probably unequalled.

The urban sanitary authority at Sutton, Surrey, has just put in hand new drainage works similar to those carried out at Norwood some time since under the direction of the same engineer, John Anstie, of Westminster. The cost of the scheme, inclusive of sewering for private roads, is estimated at £30,000 ($1,240,000); the present population to be provided for 20,000 to 25,000. The system is a separate one, and the sewage is received at the outfall in tanks where it is precipitated by the International Company's system, the effluent filtered through Polarite filters and the sludge treated by filter presses. The effluent from the filters thence finds its way over about 20 acres of ground to the Pyl Brook. The gradients obtainable are very favorable owing to the natural fall in the roads.

In connection with the post office jubilee celebration, just held at Kensington, a new instrument with the by no means euphonious title of "electro-phonoscope" was exhibited. The feature of this instrument is a telephone with receivers and reflectors whereby a speaker can see the representation of the individual with whom he is communicating. A cone disk situated in the room is strongly illuminatud with incandescent lamps, and it is on this disk that the representation of the correspondent is seen. Professor Hughes, W. H. Preece, Mr. Stroh, and Martin Roberts, are the inventors and adaptors of this system.

As a memorial of his son, Henry O. Avery, the young architect who died in New York April 30, S. P. Avery will give the Avery Architectural Library to Columbia College. This will include the books collected by Henry O. Avery relating to architecture, archæology and the decorative arts, about 200 in number, and $30,000 in money, one-half to buy more books and the other as a fund to provide for rebinding, etc. The books are to be used for reference only.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

THE PROPOSED WATER-WORKS CRIB IN CHICAGO.

New York, July 12, 1890.

To the Editor of The Engineering and Building Record:

Sir: In reference to the letter of "B. W. H.," in your issue of to-day concerning the proposed water-works crib for Chicago, I send you herewith drawings and description of the lake crib used by the Toronto water-works, thinking that as an example of a submerged water intake they may be of interest. For the purpose of making a comparison I also inclose drawings and description of the lake crib in use at Cleveland.

The Toronto crib is built of white pine, is 40 feet square, 11 feet high, and is divided by inner walls into eight compartments for stone, and a center well in which the 6 foot wooden conduit B terminates. The outer and inner walls are of 12-inch by 12-inch timbers and laid with 3-inch spaces between each course. A bottom course of six 12-inch by 12-inch mudsills was laid, and upon this a close flooring of 6 inches thickness was put down. The timbers are all 40 feet long, no splicing being allowed. The water enters the center well from the top at a distance of 11 feet above the bottom and about 15 feet below the surface of the lake. The well is 9 feet 9 inches square, is protected at the top by an oak grating A, and the sides and bottom are lined with 1¼-inch tongued and grooved sheeting, carefully calked, while the outer sides next to the stone filling are closely boarded with 2-inch plank, all fastened with ⅜-inch by 6-inch wrought-iron spikes. The grating is made of strips of oak 2 inches thick and 4 inches deep, laid on edge, with 3-inch spaces between each, blocked at the ends and all fastened together with iron rods and spiked to the crib. A piece of 6-foot pipe, about 19 feet long and fitted with flanged castings at each end, is built into the north side of the crib, projecting 3 feet beyond its outer face. The courses are secured to one another by rock elm tree-nails at the angles and where the timbers intersect, and 36 bolts of 1¼-inch diameter are carried up from the bottom to the top of the crib.

This crib is free from danger of damage by storms or fire and of obstruction by ice and drift. It is not an impediment to navigation and its durability is practically unlimited. It was built in 1882 and has since been in constant, satisfactory use.

Its cost was $1,500. The water being admitted at a point above the bottom and below the surface is alike free from floating scum, drift, etc., on the surface, and from sediment or other matter sometimes found at the bottom.

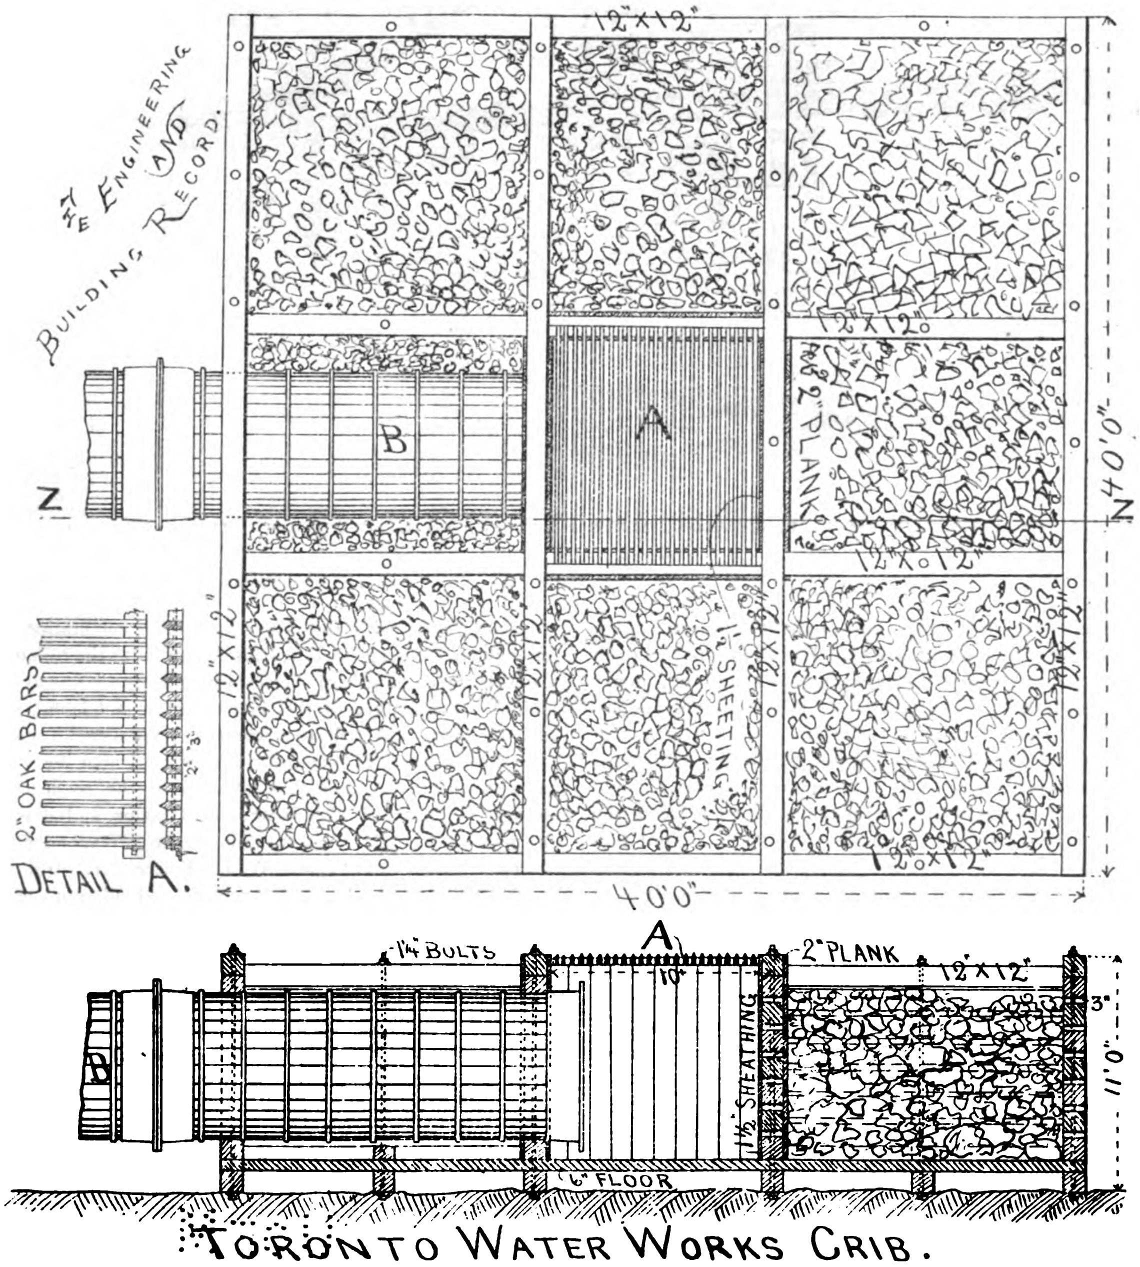
The Cleveland crib, built in 1874, at a cost of about $109,700, has a total height of 61 feet, and is pentagonal in form, each outer side measuring 54 feet. The crib is of ordinary construction, ballasted, faced with 2-inch oak plank, decked over and surmounted by a lightkeeper's dwelling and a lighthouse, 50 feet above the water. The deck is protected by a heavy wall and roof. C and D are wells to the existing and a proposed tunnel, A A A are gate wells, and O O are inlet ports. At E a section of sheeting is removed to show the crib construction. About 400 cords of stone (not shown on the drawing) are piled against the outside of the crib. A concrete mass extending to a depth of 5 feet below low water was provided for the purpose of forming a foundation for a permanent structure. to be built whenever the present one becomes unsafe from decay of the timber.

Yours respectfully,

T. J. McMinn.

Samuel Spencer, C. W. Buckholz, and G. W. Plympton, the engineering board appointed in the matter of the Brooklyn Bridge terminals, had a meeting Tuesday and organized by electing Mr. Spencer President, and Mr. Buckholz, Secretary. After a general discussion of the subject before them a resolution was adopted to the effect that they would proceed to examine such plans as had been proposed, and others that might be presented before September 1, and would give notice of hearing to all parties interested. It is announced that plans will soon be advertised for.

Paris has in the last few weeks suffered considerably from scarcity of water, and manufacturing in some sections has been seriously interfered with.



TORONTO WATER WORKS CRIB.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department.* Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

WIND VELOCITIES AND PRESSURES.

W. J. Fields New York, writes: "Can you refer me to any published table of, or data on, wind pressures for different velocities?"

[In an interesting article on the stability of chimneys, published in *The Locomotive* several years ago, is a convenient table of wind velocities and pressures, which is appended. It is proper to remark here that the relation between the velocity of the wind and its pressure against flat or curved surfaces opposed to it, is not very well understood. Proper experiments to exactly determine it have never been made. The pressure is generally supposed to increase as the square of the velocity when the opposing surface is at right angles to the direction of the wind. In such cases Smeaton's rule is to divide the square of the velocity in miles per hour, by 200; the quotient will be the pressure in pounds per square foot.

Table of Wind Velocities and Pressures.

Velocity in miles per hour.	Velocity in feet per second.	Pressure in lbs. per square foot.	Remarks.—Character of wind, etc.
1	1.467	.005	Hardly perceptible
2	2 933	.02	Pleasant
3	4.400	.045	
4	5.867	.08	
5	7.33	.125	
10	14.67	.5	
12½	18.33	.781	Fresh breeze.
15	22.	1.125	
20	29.33	2	
25	36.67	3.125	Brisk wind.
30	44.	4.5	Strong wind.
40	58.67	8	High wind.
50	73.33	12.5	Storm.
60	88.	18.	Violent storm.
80	117.8	32.	Hurricane.
100	146.7	50.	Violent hurricane, uprooting large trees.

NEW DISINFECTING APPARATUS OF THE LOUISIANA QUARANTINE STATION.

The fundamental principle of the new disinfecting apparatus of the Louisiana Quarantine Station, as described in the recently issued report of the Louisiana State Board of Health for 1888 and 1889, differs from the old one in the certain and uniform application of dry and moist heat to articles capable of carrying the germs of infection. The heating chamber in use during the years 1886, 1887 and 1888, was so constructed as to secure the heating of surfaces only of articles to be disinfected, and even this superficial heat could be applied but irregularly. The construction of the new plant was undertaken with a view to correct these dangerous weak points.

Chambers capable of generating heat under pressure, and steam tight, would secure uniformity of temperature throughout their contents, and penetration of heat into the substance of articles sought to be disinfected, each, essential requirements for absolute success. The form of apparatus possessing these requisite properties was the subject of much study and experimentation.

The plant now consists of three cylindrical steel chambers, and appurtenances necessary. Each cylinder, 50 feet long and 8 feet in diameter, is constructed of best quality $\frac{5}{16}$-inch steel, and is guaranteed to withstand a working pressure of 15 pounds to the square inch. The ends are spherical, and that facing the river, or front end, is movable, swinging open by means of a crane, when closed being secured and tightly shut by means of quickly operated screw bolts. The three cylinders rest upon saddles, are six feet apart, and are parallel with each other. For economy in steam, and for maintaining for some time the highest degree of heat attained within, they are covered exteriorly with 1¼ inches of Russian hair felt, a layer of paper, and an outer envelope of canvas, the latter well painted. At a point 50 feet in front of each cylinder commences a double, iron, elevated track which, by a movable section, continues into and throughout the length of each cylinder, being suspended from the top. On this track rolls a truck 48 feet in length, and from this truck are suspended 30 clothes racks of 5 bars each. Above the racks is a continuous canvas cover to prevent the dripping of condensed water upon clothing placed on the racks, and beneath is a wire netting to catch any falling article. The interior of each cylinder contains an arrangement for the employment of moist and dry heat, separately and together. Along the bottom are laid 10 sections of a cast-iron box, each section 5 feet in length, about 6 inches wide and 7 inches high. Through flanged ends these sections are bolted firmly together, end to end, making one continuous box, or as it is technically termed, a manifold. This manifold is divided by a horizontal partition into two compartments. On each side of the upper compartment are 120 circular openings, each 1½ inches in diameter, and distant from centers 5 inches. Into each of these openings on one side of the manifold is screwed, by means of a collar and nut, one end of a steam pipe, 24 feet long, bent circularly around the inner periphery of the cylinder, the distal end being brought over and screwed into the opposite opening, thus forming an interrupted coil of 120 pipes. Through this upper compartment dry steam enters from the boiler into the heating coil, the lower compartment of the manifield receiving the condensed water, which eventually passes out through exhaust pipes. This arrangement furnishes dry heat in the cylinder. Moist heat is admitted through a perforated steam pipe lying along the bottom of the cylinder and communicating with the steam boiler. The cylinders are provided with thermometers at each end, pressure gauges, drain-cocks and blow-off valves, the latter being set at 7 pounds pressure. The necessary heat is supplied by a 40 horse-power steam boiler, at 85 to 100 pounds pressure. The whole apparatus is covered by a shed 108 feet long and 60 feet wide, exclusive of boiler and engine-room. This shed immediately adjoins the steamship wharf, 108 feet long and 48 feet wide, at the outer edge of which there is 24 feet depth of water, and 10 feet beyond this there is 30 feet depth, permitting the landing thereat of the largest vessels. This wharf has recently been lengthened 288 feet by 24 feet wide for the purpose of placing a fumigating apparatus on a car, to be rolled to point of most convenient use.

Surmounting the shed is a cypress cistern, the bottom of which is 41 feet above the river surface, capable of holding 7,000 gallons of fluid. In this cistern is stored a solution of mercuric chloride, one part to 1,000 of water by weight. Pipes lead from the cistern to the outer edge of the wharf, and at that point have rubber hose attachments of sufficient length to lead to all parts of a very large vessel. The hoses terminate in hard rubber roses, of 6 inches face.

The fumigating apparatus, heretofore on a tug, but now proposed to be erected on rail cars on the wharf, consists of a reverberatory sulphur furnace, with 250 feet galvanized iron conductors, 12 inches in diameter, and a steam fan. The furnace, 24 inches wide, 48 high and 40 deep, is provided with four cast-iron pans, 30 inches long, 23 wide and 4 deep, each pan having over 1½ cubic feet capacity, or about 175 pounds sulphur. The pans are set on split brick, and are so placed that the current of air driven by the fan into the bottom passes over each pan of burning sulphur alternately, out through the top and along the conductors down into the holds of vessels.

The process of disinfection of vessels consists in placing all baggage, bedding, curtains, carpets, linen, etc., in fact all textile fabrics of vessel, crew, and passengers on the suspended clothes racks, which are then drawn into the cylinders by a windlass, and applying dry heat until the thermometers mark 185° Fahr., at which point moist heat is turned on, the temperature rapidly rises to 215 or 220, and the gauges usually record a pressure of seven pounds to the square inch, at which point the blow-off valves open, preventing any danger of explosion. The contents of the chamber are kept at this temperature and pressure for 30 minutes, the cylinders are then opened, and the goods turned over to their owners. The vessel in the meantime is washed down—cabins, forecastles, decks and holds—with the mercuric chloride solution, and fumigated by means of the furnace and fan. In the case of loaded vessels, washing the interior is omitted on account of danger to cargo. The holds are, however, thoroughly fumigated, and by a special arrangement of "cargo wells," the gas penetrates every interspace of cargo. These wells are constructed at port of departure, and consist of a long wooden box about 2 feet across, and reach from the bottom to the top of holds, the cargo being stowed around them at loading point. The conductor from the sulphur furnace is led into the well, the hatches are tightly closed, and, under pressure, the fumes of sulphur are driven into the vessel, the gas passing around every package envelope no matter how tightly packed, and chemical examination showed that in the case of sugar bags it penetrated to the depth of three fourths of an inch. The character of cargoes arriving at the station from infected ports is almost exclusively coffee and sugar, the former always, and the latter nearly always, in bags, neither offering obstacles to good and sufficient fumigation *in situ*.

A STEAMBOAT JOURNEY OVERLAND.

Under the title of "Struggles in Africa," John Thorburn has described, in an interesting little pamphlet, the successful transportation overland of a small steamboat from near Potchestroom to Delagoa Bay on the east coast of Africa.

The little vessel was of steel, 37 feet long and 8 feet 6 inches beam, drawing 22 inches of water, with twin screw propellers of 6 horse-power. Mr. Thorburn had ordered her of Edwards & Symes, of London, to navigate the Upper Vaal River above Kimberly, but after spending three years' time and £4,000 in endeavoring to clear the river of obstructions and having three times transported his boat overland between Kimberly and Potchestroom, a distance of 200 miles, he gave up the attempt to navigate the Vaal and concluded to take the vessel across country to Delagoa Bay, a distance of 600 miles. He started with five men besides himself and son, with the boat on a large wagon and a smaller tent wagon containing the boat's engines and tools and provisions, etc., all drawn by 32 oxen, and reached his destination in fourteen months with a loss of 22 oxen and three men, of whom two deserted and one committed suicide. He passed through fire and water, through swamps where the wagons sank to the axles and had to be laboriously pried out and jacked along inch by inch, over two mountain ranges, one of them 7,000 feet high, where his large wagon was capsized and all the woodwork of the boat smashed, besides having one side stove in and a seam ripped open for six feet in length. He made mallets and pounded his boat into shape again and riveted the ruptured seam and finally, after building several bridges and making several miles of road, he had the satisfaction of seeing the "Tembe," for that was her name, safely afloat on salt water. In all this he faithfully kept the Sabbath, and seemed much more disturbed by the sufferings of his oxen and the blisters on his son's hands than by any of the difficulties he encountered.

In fact, he seems to have rather enjoyed difficulties, for when he had finally accomplished his purpose, and "was making lots of money" with his little steamer in Delagoa Bay, his prosperity became unendurably monotonous and he sold out and started for the gold fields. It was, by the way, the report of these gold fields, which were to "surprise the world," which first led him to think of taking his steamboat to the east coast, and, curiously enough, his own farm in the Transvaal, which he sold on leaving for £1,500, proved to be one of the richest districts, and was resold a year later for £32,000.

In his brief preface Mr. Thorburn modestly ascribes his success to the fact "that when an Englishman undertakes an enterprise, however difficult, he never retreats nor leaves it until he has accomplished his object." While this statement may seem a little strong, we are not disposed to quarrel with it, as it serves to explain the other fact that Englishmen are excellent raw material out of which, in a generation or two, very good Americans can be made.

EXPERIMENTS ON THE WIRE ROPE OF THE SUPERGA RAILWAY.*

In wire rope traction the rope itself is naturally the most delicate and most important part, requiring to possess the minimum of weight, great strength, ductility, hardness, flexibility and homogeneity, a high limit of elasticity, and perfect manufacture. The line up to the Superga, at Turin, is worked by a rope composed of six plies of eight steel wires each, or 48 wires in all. The diameter of each wire is 0.078 inch, of each ply 0.315 inch, and of the whole rope 0.985 inch, the weight being one pound per lineal foot. The subjoined tables show the results of some tests of a 6 feet 6 inches length cut from this rope.

I.—*Breaking-Weight of the Single Wires of One Ply.*

Wire Number.	Total Load.	Equivalent Load Reduced to Tons per Sq. In.	Notes.
	lbs.		
1	1,032	94.90	Broke at 4.3 in. from top.
2	1,014	93 22	" 17.8 " bottom.
3	1,058	97.15	" bottom.
4	1,023	94.04	" 25.6 in. from bottom.
5	1,000	91.88	" 20 5 " top.
6	908	83.48	" 18.0 " bottom.
7	1,046	96.14	" 12.0 " "
8	1,060	97.41	" 4.0 " top.

Wire No. 6 appears to have been in some way injured. Taking this, however, as the average, the total breaking weight of the rope (net sectional area — 0.225 square inch) would be 19.3 tons.

II.—*Breaking Weight of Remaining Five Plies.*

	Total Load.	Equivalent Load Reduced to Tons per Square Inch.
	lbs.	
Ply No. 2	7,931	91 08
" 3	8,076	92.77
" 4	8,527	97.02
" 5	8,296	95.31
" 6	8,807	101.15

III.—*Elongation of One Wire under Increasing Loads.*
(Reduced to initial length = 1,000)

Load in Pounds.	Elongation.		
	Temporary.	Permanent.	Total.
220	1.55	....	1.55
264	1.80	...	1.86
308	2.18	0.01	2.19
352	2.49	0.02	2.51
396	2.83	0.04	2.87

528	3.83	0.16	3.99
616	4.52	0 40	4.92
704	5 25	0 75	6.00
792	5.95	1 25	7.20
880	6.59	2 01	8.60
908	7.38	3.65	11.03
1,003		Breaking point.	

According to the London *Builder* the famous old tower on the Town Hall buildings, Moscow, Russia, will have to be pulled down as quickly as possible, as the foundations have suddenly shown signs of giving way. Nothing has yet been settled as to the re-erection of the tower.

* A paper by A. Galassini in *Il Politecnico*, abstracted in Excerpt Minutes of Proceedings of the Institution of Civil Engineers.

A PIER SHED AND PAVILION.

THE high value of land in New York City gives rise to many expedients for utilizing space that would elsewhere be left unoccupied, which are illustrated by the recent construction of a freight shed on Pier 26, East River, which was built one story high with a nearly flat roof designed to form the floor of a pavilion to afford a pleasant river resort.

Figure 1 is a part plan of the roof trusses, which have lateral bracing, as shown, about every sixth panel. These panels have also vertical sway bracing A A in the walls.

Figure 2 is a partial side elevation showing the wall framing.

Figure 3 is an end elevation showing, at the right, the framing at the shore end, and at the left, that at the river end of the pier.

Figure 4 is a half elevation of an intermediate roof truss and column.

The building has a plank roof and corrugated iron sheathing.

This shed and pavilion was built by the Pencoyd Bridge and Construction Company, of Pencoyd, Pa., for the contractors, R. P. & J. H. Staats, New York City.

COMPARATIVE TESTS OF AN ELECTRIC MOTOR AND A STEAM LOCOMOTIVE.*

IN February, 1889, Lincoln Moss, C. E., was detailed from the Chief Engineer's Department of the Manhattan (Elevated) Railway in New York City, by the General Manager, Col. F. K. Hain, to conduct tests to determine the efficiency of an experimental "direct" electric system of motive power as compared with the present steam locomotive performance.

The section of road chosen for the experiment was 1.76 miles long, from Twelfth to Fifty-first Street on the Ninth Avenue line. This section is on the oldest and lightest of the four lines operated by the Manhattan Railway Company; the traffic is comparatively light, as is also the rolling stock; the cars weigh 12 tons each, empty, and the locomotives 16 to 19 tons, in working order. The track was in good condition, but was not up to the present standard, as the replacing of the old 50-pound rails and 5-inch ties with the standard 90-pound rails and 6 by 8-inch ties would have interfered with the electrical conductors.

The trial trains were made up of empty cars of the new standard type, which weigh 29,500 pounds each, empty; at first two were pulled, then three, and finally four; these four empty cars weighed a trifle less than the four-car trains, loaded, which are run on this line in regular service.

After the experiments with the electric system were concluded, a steam locomotive was detailed from regular service to pull the same train over the same section and under the same conditions, as far as possible, to determine the relative efficiency.

There were four generating dynamos, nominally 50 horse-power each; they could be worked in parallel or in series by means of a switch.

The current was conveyed from the dynamos to the railway structure conductors by two insulated copper cables strung on poles; at the structure the cables were divided to connect with the three positive conductors on the east, center and west tracks.

The positive conductors were of very fine copper, ⅝-inch round rods, bolted to the wooden guard timbers by insulated clamps.

The negative conductors were made up of the east line rails of each track; they were connected by ordinary angle splice bars and bolts, and also were connected electrically by copper wires at each joint, riveted in the flanges.

The positive conductors of the east and west tracks were cross connected at intervals of about 200 feet.

The circuit was closed through the motor on the track by a device which had copper leaved brushes which slid over the positive conductors, and the current after passing through the motor dynamo and its connections was returned through the driving wheels into the rails, passing thence back to the generating dynamos. Another copper brush was provided on the opposite side of the motor to bridge gaps in the positive conductors on the switches

The four driving wheels of the motor were 48 inches diameter, 6 feet between centers, and coupled to obtain the maximum tractive force; on the rear axle were two carefully cut steel gears, driven by two steel pinions keyed on the shaft of the dynamo; on this shaft were the armature and commutator revolving between the field magnets; the brushes were movable and could be reversed to change the direction of rotation, but not when under headway. The exact weight of the motor was unknown; it was known to be 10 tons, and probably weighed more. The motor dynamo was said to possess 120 horse-power.

The train consisted of four empty cars, weighing 29,500 pounds each, as before described. This train weighed somewhat less than a fairly loaded four-car train, such as is run on this line during the busy hours of the day, and the test was an attempt to imitate the run of such a train, stopping at all the stations on the way. In the absence of any other brake aside from the motor brake, all the car brakes were manned to make the stops quickly.

The average power generated was 176.8 horse-power, while the amount recovered on the track was 26.7, making the average efficiency .151 and the average loss $84\frac{9}{10}$ per cent.

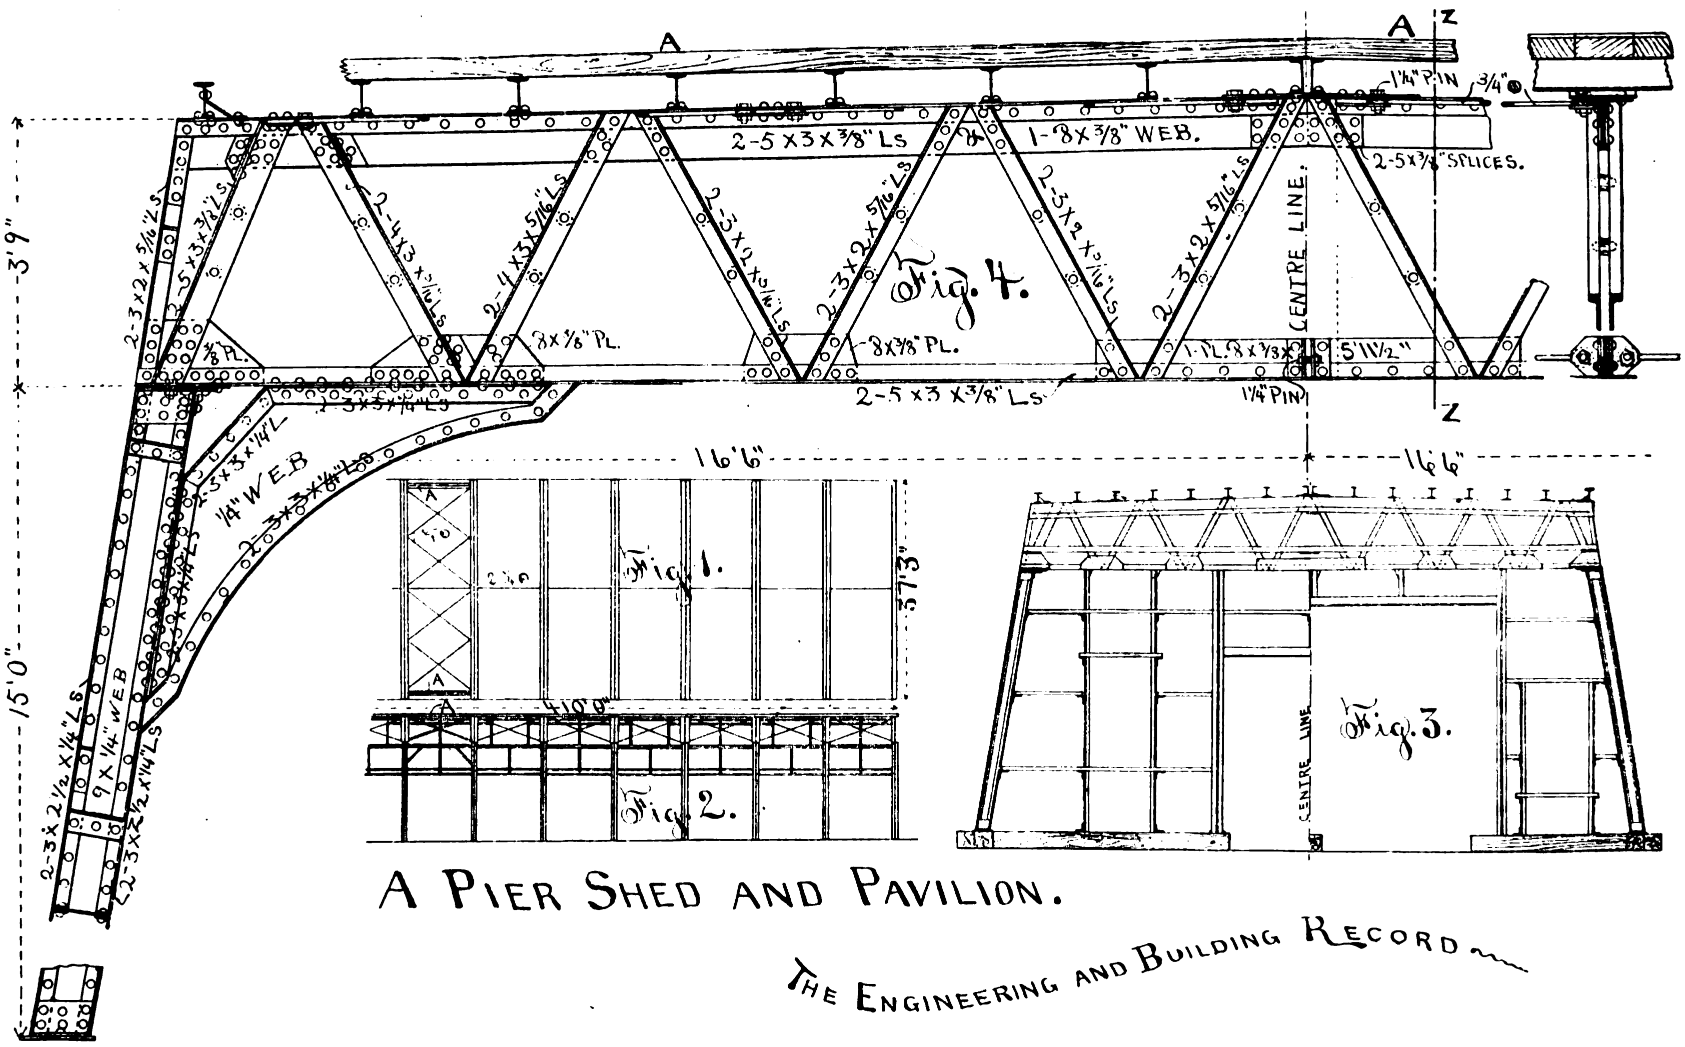
The net horse-power was calculated by formula.

$$\frac{\text{Pull of Motor in lbs. by Velocity of Train, Feet per min.}}{33{,}000} = \text{Net Horse-power.}$$

The power expended by the prime mover never went back to zero, even when the train and motor were standing at a station, at which time there was a constant average expenditure of 43 horse-power. Of this about two horse-power is lost in the engine itself, and the rest is consumed in friction, local currents, current waste, resistance and leakage. This shows nearly 24 per cent. of the total average expenditure.

The greatest power of the engine was exerted when the train was being started. For this reason it was claimed at one time that better running time could be made with electric motors than with steam locomotives, which exert the least horse-power in starting, although the steam is admitted to the cylinders at nearly full stroke. The fallacy of this belief becomes apparent by referring to some of the diagrams accompanying the paper. The net horse-power actually exerted upon the train is least when the train is being started. the dynamometer shows a low initial pull, with a characteristic falling back, and the speed line invariably shows a hollow curve of acceleration in place of the full curve which would indicate a rapid acceleration of speed, and a correspondingly great exertion of power against the resistance of the train. From a consideration of these facts, we may inquire, where was the great loss in starting, notably at Thirtieth Street station, where the driving engine indicated 395 horse-power, while at the same time, but 7 6 horse-power was being exerted to pull the train, showing less than 2 per cent. of the power of the engine transmitted to the train at that instant? The chief losses are due to several facts in the operation of electric motors.

First.—The general economy and efficiency are greatest when a certain ratio of speed exists between the generator and the motor armatures. Usually this ratio is as 2:1, the motor armature revolving but half as rapidly as the generator's armature. This is principally due to the necessity of keeping the counter electro-motive force, or the current set up by the motor itself from being driven, at a certain intensity. Of course, as the motor is simply a dynamo reversed in direction, any revolution given to its armature, whether by a current from another dynamo or by power applied to it by a belt, will generate a new or counter current, opposed to the original driving power. When the motor is just beginning to move, this counter current is small and increases as the armature revolves faster. The effect of the increase of this counter electromotive force is to diminish both the volts and the amperes, as well as the current waste, which is greatest when the motor armature is just beginning to move. The counter current could be increased till it equaled the driving force. The golden mean can only be obtained in a



A PIER SHED AND PAVILION.

THE ENGINEERING AND BUILDING RECORD

---

* From a paper by Lincoln Moss, read at the Cresson, Pa., meeting of the American Society of Civil Engineers.

motor running at a fixed speed, with relation to the generator.

Second.—The economy is greatest, other things being equal, when the load is lightest.

Third.—When a motor is being started, there is no counter current, and it is necessary to increase the resistance by rheostats, shunts, or resistance coils, or by varying the strength of the field, and these methods increase the current waste in accordance with Joule's law of current waste ($C^2 \times R =$ current waste) "C" being the current in amperes, and "R" being the resistance in ohms. In a system where a stationary motor is to be driven at a constant speed under an unchanging load, it is possible to adjust the various relations of size, speed, counter electro-motive force, etc., so as to reclaim a very good proportion of the force generated in the prime mover. As much as 60 or 70 per cent. has been claimed in such instances, but in an electric locomotive, the conditions are the very worst for economical results, by reason of the everchanging speeds and loads, and the complication of conditions; and the heavier the load to be handled and the greater the speed demanded, the more difficult and complicated the problem becomes. The most safe and reliable method of regulation is doubtless the rheostat or resistance coil. Some have used shifting commutator brushes; others have used shunts to vary the strength of the magnetic field, and in the case before us various devices were used experimentally, and the best and most reliable only were adopted.

Devices that would answer for a 10 horse-power electric street car at ordinary speeds would not answer the purpose on a 120 horse-power motor handling far greater loads with much larger variation in speeds. One effect of introducing a resistance into the circuit is to increase the horse-power, the formula for which is:

$$\frac{E \times C}{746} = \frac{\text{volts} \times \text{ampères}}{746} = \text{horse-power.}$$

The volts measuring the pressure, and the ampères the current, the current being supplied by the generators at nearly constant pressure or voltage, it becomes necessary to increase the power in starting, either by increasing E or C. It is also necessary to use a resistance to prevent burning out of the commutators and connections. At the instant of starting, much current is being used, a great deal of heat is developed by current waste and resistance, and as the counter current is practically 0, it is imperative, both for economy and safety, to increase the power by increasing the pressure (E) instead of the current (C), which is done according to Ohm's law, by introducing a resistance into the circuit.

The action of an electric motor bears some resemblance to that of a steam locomotive. In the latter, in starting, the distribution of the steam is the most wasteful, and the average pressure on the pistons is the greatest, when "notched up" so as to expand the steam more economically, the economy is very much improved, and the average pressure falls comparatively low, but, although low, it is applied so much more rapidly that a greater horse-power is developed. So in an electric locomotive, the electrical pressure is greatest when starting, because of the "resistance" introduced, and the current used is greatest, owing to the absence of counter electro-motive force; but as the speed increases and the resistance is cut out and the counter current increases, the electrical pressure becomes less, and also the current used, for it is evident that if the speed of the motor was increased enough the new or counter current generated by the driven motor acting as a generator would equal the current derived from the generating dynamo, and no work would be done by the motor; so that when the motor is working rapidly, and the impulses are of low pressure and quantity, the efficiency is the greatest, although it seems like a strange kind of efficiency which depends upon the development of an opposing force.

Of course the heavier the load, or the steeper the grade to ascend, the greater is the "resistance" required in order to increase the horse-power, and as the speed of ascent on a grade is below the normal, the counter current is small and the current waste is greater, as more current is used, so that we might expect to find at Thirtieth Street, which is at the foot of the $1\frac{86}{100}$ per cent. grade, the greatest waste of power and the least efficiency. On this occasion the rear end of the train was on the down grade. When the current was switched into the dynamo to start the train, the resistance was immediately felt at the power station, the dynamos and driving engine slackened their speed about 10 per cent.

At first, in these experiments a current of low potential was used, but as the loads were increased and the usual stops and starts made with the load, it became necessary to increase the power. This was done by increasing the speed of the engine from 80 to 100 revolutions per minute, the effect of which was to increase the potential by revolving the dynamo armatures faster. While the current used was not deadly, it was strong enough to knock a man off his feet, and as it was exposed not only in the conductors but also in the wheels, side-rods and other mechanism about the motor, in practice, it would have been imperative to use a pressure in the neighborhood of that prescribed by the London Board of Trade, 300 volts.

To obtain a given horse-power by a low potential current would mean the use of more current and larger conductors for the horse-power. If we reduce the volts, the ampères must be increased, and the ampères are the current divided by the resistance or $C = \frac{E}{R}$. We should also recollect that the current waste is equal to the square of the current multiplied by the resistance, or $C^2 \times R$, so that the economy of high tension currents is apparent, a point well understood by electric light companies. Of course the higher the E M F the better must the insulation be, just as high pressure engines and boilers require better construction. Had the voltage been kept at the original low E M F, the economy would not have been as good as that reached.

High speed of armature is an important requisite, and as yet no means have been found practical to apply the motor armature to the driving axle direct. Direct action and elimination of gearing and intermediate contrivances is the best for all engines, whether stationary, locomotive or marine, and the electric motor was undoubtedly at a disadvantage in being compelled to use gearing to reduce the speed; especially should we expect quite a loss in friction, because the pitch lines of the gear wheels and pinions were constantly varying as the axles moved up or down in the pedestals. This motor originally was built with V friction gearing, which was found to be unreliable and useless owing to the oscillations. The loss due to varying counter current and current waste is of course common to all electric motors, from whatever source the current is derived. Some inventions have been made to obviate this great source of waste, by keeping a constant rate of armature speed and using variable intermediate gearing, and other inventions have been made with this purpose in view; but spur gearing remains still the standard. The objectionable use of resistance is done away with on storage battery motors by grouping the cells which represent about two horse-power each, into series, so that the operator may switch only one set or all into the circuit, and thus obtain a current of variable intensity and pressure. If but one motor on a direct system circuit was in use, it would be possible to apply the same principle to the direct system, but in practice there would be a number of motors on a section at once. Some would be just starting and calling for much current and high potential; others might be in full speed and calling for a current of lower pressure and quantity, so that it would be impossible to suit all the varying conditions at once. A great many trials were made under varying conditions, and one interesting fact among others developed, is, that the economy with light trains at higher speeds becomes poorer, apparently contrary to the general principle that the economy of stationary electric motors increases with the speed and the reduction of the load, and many believed that a better showing would be made with such tests. It is true that tests made with light trains of two or three empty cars run at a high speed, but making no stops, showed much better results, but such conditions are not at all practical in operating elevated or other railways. It is true that a lightly loaded stationary motor, running at a nearly constant high rate of speed, will show maximum economy, but in the case before us, where the motor was changing its speed continually, and stopping and starting, the rule will not apply.

It being evident that the electric motor had not sufficient power to handle an average train under working conditions, and that the generating machinery was not powerful enough, it was considered advisable, in order to secure an accurate comparison with a steam locomotive, to detail one to pull the same train of cars over the same track, using hand brakes and reducing the running time to that of the electric motor. A number of tests were made on two occasions, some at slow speed, some on schedule time, and one run was made to ascertain the best performance of the engine, which, incidentally, propelled the train at an average net speed of 16⅔ miles an hour, making all the stops.

The locomotive, No. 67, was by no means the best on the line, and was not in the best condition, as it had a few days before been equipped with new brasses all around, and newly planed valve faces, all of which require plenty of time and oil to bring their services to a good fit and polish.

The cylinders were 11-inch bore by 14-inch stroke. The four drivers were 36¾ inches diameter. The concentrated working weight on drivers was 23,900 pounds. The total working weight was 37,900 pounds. The maximum boiler pressure was 140 pounds per square inch.

The same corps of observers made the test, using the same instruments and methods.

The average indicated horse-power was 25.92; the average net horse-power was 21.95, making the efficiency of the prime mover .85.

The net speed and net horse-power are both lower than in the electric motor test, as the speed was three-tenths of a mile per hour less.

In order to arrive at a conclusion respecting the relative economy of the two systems of motive power, the writer assumes the most tangible measure to be the cost of producing one net horse-power at the draw bar. Under actual working conditions the locomotives develop on the average one indicated horse-power per hour with 6 pounds of good broken anthracite coal, which costs about $4.20 per long ton on board the engines of this line. In a short time this expense will be largely reduced by the new coaling plant at the Harlem River. This coal is very good, averages a pound per lump, and generates 7 pounds of steam per pound of coal, in the average locomotive boiler. The city charge for croton water is $1 per 1,000 cubic feet.

The machinery used in the electric plant was of an economical type, but could have been better still by investing more money in the plant. Assuming that the engine was compounded and used high pressure steam, and assuming that the plant could have been located on the water front so as to obtain condensing water, and assuming that an inferior coal was burned, a high average figure would be the development of one indicated horse-power per hour with three pounds of coal. Assuming that the inferior small coal would cost, after unloading, trimming, storing, rehandling and delivering at furnaces, $3.30 per long ton, and assuming an hourly consumption of steam of 20 pounds per horse power, with an efficiency of .15 from the prive mover, the cost of one net horse-power by electricity would be:

Let $x = \frac{\text{I. H.-P.}}{\text{N. H.-P.}} =$ indicated horse-power required to produce one net horse-power at the draw-bar of motor;
" $a =$ pounds of coal burned per indicated horse-power hour;
" $b =$ pounds of water evaporated per pound of coal burned;
" $c =$ total cost of coal per pound at the furnace;
" $d =$ cost of water per pound:

then $x\,a\,c =$ cost of coal, and $x\,a\,b\,d =$ cost of water, which are, respectively, $ .03 and $ .001, making the total cost per net horse-power hour $3\frac{1}{10}$ cents. In the case of the locomotive ($x\,a\,c = \$\ .012$) + ($x\,a\,b\,d = \$\ .001$), = total cost per net horse-power hour, $1\frac{8}{10}$ cents.

The ratio of cost by locomotive to electric motor is $1:2\frac{88}{100}$.

This is entirely exclusive of extra force at generating stations and additional repairs, and there could be no reduction in the working force on board the motors, whether steam or electric.

The foregoing estimate can only hold good with reference to the electric motor at a speed of $9\frac{4}{10}$ miles per hour, for beyond that the ratio of indicated to net horse-power rapidly increases. Carrying out the curve of apparent increase of indicated horse-power per ton of train from 12 to 15 miles per hour, it seems very fair to assume an expenditure of nine indicated horse-power per ton of train at that speed, which would bring the ratio of cost up to 1:4.7—by applying the previous method.

The question may be asked, what would have been the efficiency, if, instead of one train being run on the trial section, a number of trains had been run? The line resistance and other demands for power when no train was being moved would probably have remained the same, namely, 43 horse-power; this constant loss would have been divided among, at most, four trains on this section, which would reduce the average horse-power per train, at the low speed of 9.4 miles per hour, to 162.5 horse-power, while the net horse-power required would remain 26.7 giving an efficiency of $16\frac{4}{10}$ per cent., but, on the other hand, the evidence goes to show that if the speed was brought up to the regular average of 15 net miles per hour, the efficiency would have shrunk to about 8 or 9 per cent., and this would again be reduced by lowering the potential of the current to a safe limit.

A conservative estimate, based on these facts, would be that the cost of direct electric propulsion would be four times that of steam locomotion.

ALGÆ GROWTH IN RESERVOIRS.

IN the course of a paper on algæ growth in reservoirs, recently presented to the New England Water-Works Association, F. F. Forbes, Superintendent of the Brookline, Mass., Water-Works, stated that about five years ago Brookline built a high service system, and the water for this was stored in an iron tank 50 feet in diameter and 30 feet high.

The same growth appeared here which had caused so much trouble in the low service reservoir, although no water from the reservoir was pumped into the tank. The frequent change of water, which was unavoidable in a tank of such small capacity, increased the growth, and it was even worse than in the low service reservoir. Three years ago the tank was roofed over, excluding all sunlight, since which time no green algæ has been found, and the water has been free from taste and smell.

There is a class of plants, however, which thrive as well in complete darkness as in sunlight; but such plants are not able to make their own food, and are wholly dependent on food made by other plants. Water which contains vegetable solutions in sufficient quantities with certain organic matter, might develop a very extensive growth in total darkness.

In the Brookline filtering gallery and high service tank there is a slight growth of crenothrex, a plant of this kind, but in too small amount to do injury; and it is very doubtful whether waters which contain no more vegetable matter in solution than those furnished by Newton, Waltham, Hyde Park and Brookline will ever be troubled by plants of this kind.

Where it is necessary to store ground water, it should be in covered reservoirs or tanks, and in planning new works where water is obtained from such sources this feature should receive prominence.

NEW ENGLAND WATER-WORKS ASSOCIATION SKETCHES.

(Continued from page 85.)

STAND-PIPE CONNECTION AT MARBLEHEAD WATER-WORKS.

THE accompanying illustration, showing details of the stand-pipe connection at the Marblehead, Mass., Water-works, was contributed to the Portland convention of the New England Water-works Association by F. L. Fuller, C. E., of Boston, Mass.

Two sections and a plan are given, explaining all the main features of the arrangement. The supply-main to the stand-pipe enters the latter through the bottom. There is a free flow of water from the stand-pipe through the check valve N, shown in the plan, and by partially closing the gate M an increased pressure can be obtained through the town while pumping.

SPECIFICATIONS FOR CAST-IRON COATED WATER-PIPE.

IN the course of a discussion on water-pipe tests and standard sizes of pipe at the Chicago meeting of the American Water-Works Association, Thomas W. Yardley, on request, submitted the set of specifications for cast-iron coated water-pipe given below, and first presented to the American Institute of Mining Engineers at the Washington meeting in February, 1890.

Mr. Yardley briefly explained that in many years experience as a maker and purchaser of cast-iron coated pipe he never met with any standard form of specifications for such. Each water–works company employing a hydraulic engineer has, under his direction, prepared complete specifications for the particular conditions required, but one cannot find that any two are alike, and each foundry, in bidding for the supply of such pipe, makes the price to cover the conditions required. The specifications given, he thought, would be found useful to water-works companies and others requiring pipe of this kind, the conditions being all reasonable and capable of being carried out by makers without additional cost and with advantage to purchaser.

Section 1 gives the kind of pipe, with its general characteristics.

Section 2 specifies that neutral pig iron shall be used, since such iron possesses the strength required and is uniform in shrinkage.

Section 5, requiring makers to give the brands of pig iron used in the cupola, is intended to guard against the use of cinder iron. The characteristics of the ores used in blast furnaces give to each its reputation, and the furnaces using cinder are all well known.

Section 7, providing that the shell of each pipe shall be measured for thickness throughout its entire length, enables the inspector to determine whether there are thin places near the middle of the pipe, where such imperfections are most likely to occur. An inexpensive instrument adapted to such measurement has been devised.

Section 8 provides for a test bar, from which to determine the transverse strength of the iron. This bar is convenient in form, can be made with very little cost to the maker, and will give the most satisfactory test of the strength of the iron under the conditions to which the pipe will be subjected in service.

Section 11, requiring that all pipe shall be stripped immediately, if taken from the pit before cooling, is very important, for the reason that when pipe is taken from the pit hot a deposit of loam is frequently left in spots on the outside, and wherever this occurs the cooling is irregular and the shrinking strains are unequal. The weakness thus produced may not show under the subsequent hydraulic test, but may be developed after the pipe has been subjected to rough treatment in railroad and other transportation into the trenches.

SPECIFICATIONS FOR CAST-IRON COATED WATER PIPE.

SECTION 1. The pipe shall be of the usual kind known as "Hub and Spigot;" each pipe shall be twelve (12) feet in length from the bottom of the hub to the end of the spigot; the form and dimensions of hub and spigot ends shall be as marked on and shown by drawings to be furnished or approved by purchaser.

SEC. 2. The metal shall be of the best quality for the purpose, made from what is commercially known as "Neutral" pig iron, which shall have been made from iron ores without the admixture of cinder, and when cast into pipe the metal shall be tough, and of such density and texture as will permit its being easily cut and drilled by hand.

SEC. 3. Each pipe shall have cast on the exterior surface of hub........in raised Roman letters, one and one-half (1½) inches long, and shall be further marked in like manner with letters and figures to designate the maker of the pipe and the year; also serial numbers shall be cast on each pipe, commencing with a number to be designated by the purchaser.

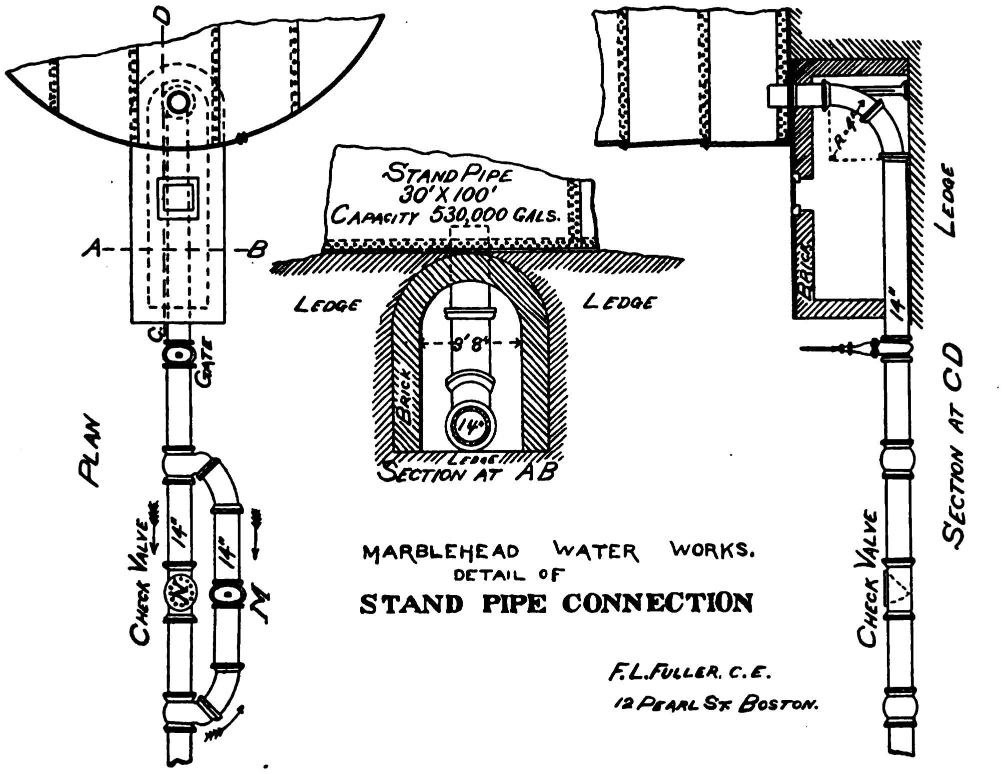
SEC. 4. The pipe shall be cast in dry sand molds, or flasks, placed vertically, and shall be of the several diameters named in the contract. The shell shall be of uniform thickness of metal, smooth and sound, without cold-shuts, lumps, swells, scales, blisters, sand holes, or other imperfections; truly cylindrical; of full diameters; and with interior and exterior surfaces concentric.

SEC. 5. Chemical analysis of the iron used shall be given whenever asked for, and a written daily report shall be furnished to the inspector, giving the brands of pig iron used in each day's melting.

SEC. 6. Each ladle of iron from which the pipes are poured shall be designated by a consecutive number, beginning with each day's work. A daily record of pipes cast shall be kept and furnished to the inspector, and must record the number of the ladle from which each pipe was poured, as well as the number on the pipe.

SEC. 7. The shell shall be of uniform thickness throughout its entire length. Should the inspector find in any one place a variation in thickness of more than ten (10) per cent. less than that specified in the contract, such pipe shall be rejected.

SEC. 8. From each ladle of melted iron there shall be cast one test bar, not less than twenty-six (26) inches long, two (2) inches wide, and one (1) inch thick. This bar shall be tested for transverse strength when loaded in the center, twenty-four (24) inches between supports (narrow sides vertical), and shall carry a center breaking-load of not less than two thousand (2,000) pounds, and show a deflection of not less than $\frac{3}{10}$ inches before breaking. This bar shall be cast as near as possible to the specified dimensions without finishing up; but correction shall be made for variation of width and thickness; and the corrected result must conform to the above requirements.



MARBLEHEAD WATER WORKS. DETAIL OF STAND PIPE CONNECTION

SEC. 9. If any test bar shows a breaking strain or deflection less than the above requirements, all pipe made from the corresponding iron shall be rejected.

SEC. 10. The maker shall furnish to the inspector in charge two wrought iron rings (male and female templates), the one showing the outside diameter of the spigot end, and the other the inside diameter of the hub end of each size of pipe; and the said pipe shall conform in diameters to the respective templates.

SEC. 11. The pipe shall be thoroughly cleaned, both inside and outside, without the use of acid or other liquid. If the pipe is stripped while above a dark blue heat, all sand must be removed from the outside immediately.

SEC. 12. When the pipe is so cleaned, it shall be heated to 300° Fahr., and immersed in a bath of coal pitch varnish of an equal temperature. When the pipe is removed from the bath this coating shall *fume freely*, and set perfectly hard within one hour from the time of removal. No pipe shall be tested by hydrostatic pressure until the varnish has become hard.

SEC. 13. When coated the pipe shall be subjected to a test by hydrostatic pressure of not less than four hundred and fifty (450) pounds per square inch for 6-inch and 8-inch; four hundred (400) pounds for 10-inch and 12-inch; three hundred and fifty (350) pounds for 16-inch and 20-inch; three hundred (300) pounds for 24-inch and 30-inch, and two hundred and fifty (250) pounds for all 36-inch diameter and upwards; and while under such pressure the pipe shall be subjected to an additional test by a series of smart blows at various points throughout its entire length with a three (3) pound hammer, attached to a handle sixteen (16) inches long. If any failure is shown in the pipe during this test it shall be rejected.

SEC. 14. The weight of each pipe must correspond as nearly as possible to the standard named. Any pipe which may fall short over five (5) per cent. of the standard weight shall be rejected, and no weight shall be allowed or paid for any pipe that shall exceed two (2) per cent. of the standard weight. These requirements shall be determined by the weight of each pipe separately.

SEC. 15. All special castings, such as "Ell's," "Tee's," "Y's," bends, crosses, etc., shall be made from the same mixture of pig-iron as has been approved for pipe, and all such castings shall be submitted to the same care in cleaning and heating, and the bath shall be used under the same conditions as for straight pipe.

SEC. 16. All appliances necessary for the inspector to carry out the requirements of these specifications shall be furnished by the maker free of cost to the purchaser.

POWER FROM HOT WATER.

RESPECTING the power, which can be stored up in a boiler charged with steam and water at high temperatures, the London *Engineer* some time ago published the following calculations in an article on the Nordenfeldt submarine boat:

If the pressure in a boiler is lowered the temperature falls, and part of the sensible heat of the water becomes converted into latent heat by evaporation. The two boilers of the Nordenfeldt boat contain about 27 tons of water. The pressure of the steam is, say, 160 pounds above the atmosphere, or 175 pounds absolute. The corresponding temperature is 371° Fahr. The engines will work well with steam of 65 pounds absolute pressure, having a temperature of 298 degrees. In falling from one of the temperatures to the other each pound of water gives out $371 - 298 - 73$ heat units. There are 60,480 pounds of water and $60{,}480 \times 73 = 4{,}415{,}040$ heat units. Each pound of steam at 65 pounds pressure will represent 904 units, so that the water will be able to supply $\frac{4415040}{904} = 4883$ pounds, nearly, of steam of 65 pounds pressure after the ship has been submerged. Assuming that the engines use 20 pounds of steam per horse-power, per hour, we have $\frac{4883}{20} = 244$ horse-power per hour.

THE Paris *Annales des Ponts et Chaussées* for February contains a description of the seaports of Holland, including the construction, equipment, etc., of docks, sea walls, canal bridges, etc., which are elaborately illustrated. The March number contains an article on filtering, in which, after consideration and analysis of conditions, the author deduces mathematical formula which he considers explanatory of many phenomena and consistent with numerous practical and experimental observations that he records

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

ROPES AND HITCHES.

Rules for the strength of ropes, definitions of riggers' terms and cuts of simple hitches, were published in article No. LI. of this series, page 61, Vol XIX. In continuation of the subject the following description is given of other simple hitches useful for bridge and roof erection and ordinary field work.

The illustrations are made from drawings of small models that were mounted on cards, furnished by a rigger and bridge erector.

Figure 17 is a sheep-shank, used to shorten a rope, and can be used where neither end is free.

Figures 18 and 19 are both shortening hitches, which can be used only when one end of the rope is free. They will not become undone when the strain is relieved, as a sheep-shank may.

A short bar or toggle (T, Fig. 20, 21, 22 and 23) is sometimes used in making hitches that must be very quickly undone.

Figure 20 is a shortening hitch to take up unused rope, and is made to pull out when T and T are removed.

Figure 21 is a boat knot, and is used when weights are to be carried from T. By raising the weight slightly T is loosened and may be removed and the knot then falls to pieces.

Figure 22 is a sheet bend, and is a valuable hitch for joining two ropes. It is perfectly secure, can not jam, is easily made and is undone by removing T. Care must be taken that T does not fall out accidentally through any intermission of strain in the rope.

Figure 23 is a larks-head, principally used for mooring boats. The free end must be stopped, and there is danger of the toggle falling out if not specially secured.

Figure 24 is another form of larks head that makes a secure hitch and cannot jam, but is rather difficult to tie.

Figure 25 is another form of larks-head. In the finished hitch the bight B must be drawn close. This hitch cannot come loose, and is likely to jam very tightly at B.

Figure 26 shows how this hitch is commenced. The bight B being first made and the free end crossed through it, carried one round turn about the ring R and brought back across the standing part at A, thus forming one-half the hitch; second half is similarly made alongside in reverse order.

Figure 27 is a dog-shank, used for joining two pieces of chain, etc.

Figure 28 is a jury-mast hitch, often used at derrick heads, where it affords secure hitches for several guys without bulky knots.

Figure 29 is a bowline hitch.

Figure 30 shows how to commence it. This is one of the most valuable hitches, and is very generally used; it is perfectly secure, cannot jam, and is quickly made and unmade.

BUILDING IN EARTHQUAKE COUNTRIES.

In concluding a paper on the above subject, read a short time ago before the British Institution of Civil Engineers, the author, John Milne, says that to mitigate the effects of earthquakes it is essential to select a building site where it is known that the ground suffers but slight motion. This is generally hard, high ground. Soft ground, slopes, and scarps should be avoided.

Having obtained a site, one of two general systems of construction can be followed—namely, either to give so much rigidity to a structure that it may be likened to a steel box; or to erect a light building which has so much flexibility that it may be compared to a wicker basket. Both these structures should be light, especially their upper parts.

Buildings of the former class which, from the materials entering into their structure, are unquestionably heavy, include ordinary structures of stone or brick (by preference hollow bricks). These should rise from a deep foundation, have a free basement, walls of unusual thickness, and be well bonded and tied together. The roofs should be light. In this case the strength of the building more than outweighs the ill effects due to its weight. Such buildings are durable, and relatively safe against fire. They are suitable for all climates; but they are, in respect to all other buildings, exceedingly expensive. For this latter reason, this type of structure can only be employed for buildings of importance.

Light buildings, which have sufficient strength and flexibility to overcome effects due to their own inertia when shaken by an earthquake, include nearly all well-constructed structures of wood or iron. The former, however, are neither durable, safe against fire, nor impervious to heat and cold; but these objections may be practically overcome, and wooden buildings are cheap. Iron buildings are relatively expensive, and, without special arrangements, they are too hot in summer and too cold in winter.

A type of building which offers the same advantages as a brick or stone structure against the danger of fire, and in being suitable to resist changes of temperature, and which is also much cheaper, and at the same time safe against all ordinary earthquakes, is the barrack system so strongly recommended in Italy. The framing may be of wood or iron, while the filling-in which forms the walls, which ought to be as light as possible, may consist of hollow bricks or a concrete of light material. For this latter purpose, in Japan, a concrete might be made of the pumiceous light scoria, of which there is an abundance. Mr. Milne also calls attention to the possible employment of cylindrically-formed or drain-pipe shaped bricks, such forms being stronger than bricks of the ordinary rectangular section.

In all these buildings, whether they be of masonry, iron, wood, or built according to the barrack system, the roofs must be light, openings must be in proper positions, walls must be of moderate height. Ordinary structures of brick or stone are usually bad, while timber structures with a masonry front are worse. To resist earthquake motion, lightness and strength are essential, and, if possible, a certain elasticity. Weight, unless it is accompanied by great strength, is a quality to be avoided.

For buildings of importance, Mr. Milne suggests the use of brick. Let the buildings be placed in good situations, the brickwork well bonded and unusually thick, and let them rise from deep foundations. Roofs should be light. For ordinary buildings, unless the barrack system be adopted, Mr. Milne suggests that, for a country like Japan, frame buildings should continue to be used. To improve them, they require more diagonal bracing, lighter roofs, and some protecting covering against fire.

Mr. Henry Dyer's opinion, that Japanese structures are exceedingly ill adapted to resist earthquake motion, is one with which Mr. Milne does not concur. In 1880 and 1887 ordinary Japanese buildings resisted earthquake motion much better than ordinary European-built bungalows and framed structures with a stone or brick facing. The Japanese buildings which suffer most are the fire-proof stores which Mr. Dyer remarks, generally withstand earthquakes. Mr. Dyer states that substantially built buildings of the Imperial College of Engineering in Tokio have suffered but little. Cracks, however, have been found; and at the time of earthquakes these have been observed to open or shut, and occasionally to extend in length. Mr. Dyer's opinion is that the cracks, which chiefly occur in the dormitory and museum at the College of Engineering, were not formed by earthquakes, but by bad foundations. If the foundations had been better, possibly the cracks might not have occurred; but that does not alter Mr. Milne's opinion, which is that they were caused by earthquake movements acting upon the weaker parts of the buildings. On the 15th of February, 1887, the author's own house, which may be included in the buildings referred to by Mr Dyer, was cracked from top to bottom by an earthquake, and many stones forming the corners were displaced ¼ inch. The building is of brick, with a stone foundation, stones at the angles, and an internal wooden frame. At the workshops at Akabane, in Tokio, which buildings are referred to by Mr. Dyer as satisfactory structures, one of the chimneys was, in 1880, cracked by an earthquake, and had to be strengthened by iron bands. Mr. E. G. Holtham, when discussing an earlier paper by Mr. Milne on the same subject, remarked that in Japan timber-framed houses faced with stone are considered earthquake proof. As a matter of fact, although many such buildings exist in Japan, it has often been observed that they have been seriously damaged while other buildings have escaped. They are one of the worst types of buildings for an earthquake country.

According to statistics presented at the Chicago meeting of the American Water-Works Association in May, water-works in the United States have trebled in the last ten years, growing from 660 in 1881 to 1,900 to-day. The invested capital is $500,000,000; the annual revenue is $50,000,000; the mains are 30,000 miles long, and there are 2,000,000 taps.

THE RELATIVE ECONOMY OF STAND-PIPE AND TRESTLE TOWER FOR WATER-WORKS.

IN *The Technic*, an annual published by the Engineering Society of the University of Michigan, is a paper contributed by H. S. Crocker, of the class of 1889, which is reprinted as of interest to those who may have to decide such a question as is there discussed, and in the hope that it may serve to draw forth some expression of opinion from those who have investigated the question for themselves. Of course there are cases where all the water that a stand-pipe contains from the ground up is liable to be drawn upon, and then the question could not be raised, but perhaps more frequently only the water in the upper part of the stand-pipe is really useful, and the question then arises as to whether it is cheaper to continue the cylinder down the same size, making it strong enough not only to carry its own weight but to resist the increasing bursting pressure of the water, or to use a trestle support. From the fact that to support a given tank the cost of the trestle will approximately vary as its height, while on account of the increase of the water pressure with the height, the cylinder if extended down will increase in weight and consequent cost much more rapidly than the height, it is obvious that no general answer can be given to the question. For a small elevation it may be cheaper to extend the cylinder, while for a greater elevation it would probably be much cheaper, as Mr. Crocker has found, to use a trestle.

It is interesting in this connection to note that Chester B. Davis, of Chicago, in designing the stand-pipe for the water-works at Elgin, Ill., which is 30 feet in diameter and 115 feet high from the ground, found it cheaper to use a monolithic concrete base 20 feet high than to extend the cylinder down to the ground.

From an æsthetic point of view it may be said that if anything can more effectually disfigure a landscape than to have a bald sheet iron cylinder erected on its most conspicuous elevation it would be to have a section of the same cylinder set up in the same place on stilts.

Happily the designs for water towers submitted in our recent competition show that the bare cylinder can be readily clothed in forms of architectural beauty, and if only the upper part of the cylinder is useful then the surrounding structure readily takes the place of the supporting trestle, and with very little additional expense.

The paper is as follows:

In pursuing the investigation upon which this article is founded, the writer has carefully designed a stand-pipe and trestle-tower including all details, under assumed conditions which are applicable to most of our western cities of moderate size, so many of which have erected stand-pipes similar to the one here described. The two structures will first be considered separately, and then the results will be compared in detail.

STAND-PIPE.

The pipe designed by the writer is 120 feet in height by 20 feet in diameter, and has a capacity of 282,000 U. S. gallons. The material is wrought-iron plate of the best quality, arranged in horizontal courses of 4 feet in height, and of plates 7 feet 10¾ inches net length.

The allowable stresses which have been assumed in its design are as follows: For safe working strength, tension = f = 15,000 pounds per square inch; for safe working strength, compression = c = 12,000 pounds per square inch; for safe working strength, shear = s = 9,000 pounds per square inch.

These assumptions were thought to agree well with the best practice under like conditions. The thickness of plates, size and pitch of rivets, with their number and arrangement, were determined by the formula

$$pr = As = tdc = tf \,*$$

in which A = area of section of rivet in inches; t = thickness of plate in inches; d = diameter of rivet in inches; p = pressure in pounds per square inch, and r = radius of pipe in inches. The results are tabulated by courses, beginning at the bottom.

For the horizontal joints only one row of rivets was found to be necessary, and their distribution was as follows:

First 12 courses from bottom, ⅞-inch rivets, pitch 3¼ inches.
Second 20 " " ¾ " " 3½ "

To sustain the pipe against a wind pressure due to an assumed velocity of 90 miles per hour, 12 2-inch anchor bolts were placed at equal intervals around the circumference, and extended through the masonry. To prevent the collapsing of the upper portion of the pipe two rings, three inches in width by one-half inch in thickness, were placed around the circumference, one of them being at the top and the other four feet lower.

VERTICAL JOINTS.

	No. of Courses.	Thickness of Plate.	No. Rows Rivets (staggered)	Pitch of Rivets.	Size of Rivets.	Lap.
1st	5	⅝"	3	3¼"	1"	7½"
2d	2	9/16	3	3	⅞	7½
3d	2	½	3	3	⅞	7¼
4th	3	7/16	3	3	⅞	7¼
5th	4	⅜	3	3	⅞	7
6th	2	5/16	3	3	⅞	7
7th	2	5/16	2	2½	⅞	4½
8th	1	5/16	2	3	⅞	4½
9th	2	¼	2	2½	⅞	4¼
10th	2	¼	2	3	⅞	4¼
11th	2	3/16	2	3	⅞	4¼
12th	5	3/16	1	3	⅞	2½

The masonry is to be of coursed sandstone, with a top course of limestone, octagonal in plan, upper surface 480 square feet in area and the bottom area 644 square feet. The depth, of six feet, was figured as being amply sufficient to prevent the settling of the structure and the injurious action of the frost. Under the masonry is placed a layer of concrete one foot in depth.

The pipe is to be provided with a light ladder on the outside, and all ironwork, whether exposed to the weather or not, is to be given three coats of Ironclad paint.

The bill of materials includes everything, with the exception of transportation and profits of contractors.

TRESTLE TOWER.

The trestle tower consists of a tank 33 feet in height by 20 feet in diameter, supported on a trestle of four inclined posts with four panels of bracing. The height of the trestle proper is 92 feet, making a total height, including the tank, of 125 feet, or the same as that of the stand-pipe. The breadth of base is 49 feet, giving a batter to the posts of one in four. The tank proper is identical with the upper 33 feet of the stand-pipe and needs no description. It has a bottom of one-quarter inch plate iron and is supported on floor timbers which rest on a system of girders, these being supported directly by the posts. The general plan and arrangement of parts composing the tower is similar to that of the trestle tower built some years since for the water-works at Princeton, N. J. Each post rests on a masonry pedestal 4 feet square on top and 7½ feet square at the bottom, with a depth of 7 feet. The posts are anchored to the foundation by one-inch rods.

The batter and width of base may seem rather excessive, but the width of base as here given is the least allowable to satisfy the condition that there shall at no time be any tension in the posts on the windward side.

In determining the stresses the same assumptions in regard to wind pressure were made as in the case of the stand-pipe. The tower is to be provided with a wrought-iron ladder and thoroughly painted.

The struts are calculated by Gordon's formula, the safe working strength for compression being assumed as 12,000 pounds per square inch.

In the case of both stand-pipe and tower 10 per cent. was added to the weight of plate iron for lap and rivets, the weight thus obtained being given in the bills of material.

Of course the capacity of the tank of the trestle-tower is but little more than one-fourth that of the stand-pipe, but it has the same head of pressure due to elevation and performs all the functions of the stand-pipe in the way of reducing shocks in the mains which would result from the direct pressure system. The water in the lower part of a stand pipe is thought to serve no useful purpose, and to be a source of inconvenience rather than otherwise.

The approximate cost of the stand-pipe as given by the bill of materials is $6,700, and the cost of the trestle tower $4,300. These results show at least in the present case the superiority of the trestle tower in almost every particular in point of economy.

Had a less expensive class of masonry been used the difference in cost would have been reduced somewhat, but reference to the figures will show that the cost of iron for the pipe was $3,480, while that of the tower was only $2,130, or a difference of about one-third in favor of the tower.

The labor of erection is assumed as the same in both cases, but a difference of a large per cent. either way in labor would have but small effect on the ratio existing between the costs of the two structures. For different heights of structures the differences in cost will vary, but when the trestle is used the odds will always be in its favor over a stand-pipe of equal height and size.

These results are, in the opinion of the writer, sufficient to prove that the trestle tower is to be preferred to the stand-pipe in every case where economy is a point to be considered, and as for appearance and durability the trestle tower ought certainly to hold its own.

---

* The last part of this formula should be

$$\frac{t\,(p-d)\,f}{p}$$

and in this case p does not stand for pressure per square inch, but for pitch of rivets. This formula will of course be strictly correct only for those causes in which there is one rivet per inch of vertical joint. For the other causes the second and third parts of the formula, As and tdc, should be divided by the pitch of the rivets and multiplied by the number of rows.—EDITOR.

DOMESTIC PLUMBING HEATING LIGHTING & VENTILATION ENGINEERING

EXPANSION JOINTS IN THE UNDERGROUND PIPES OF THE NEW YORK STEAM COMPANY.

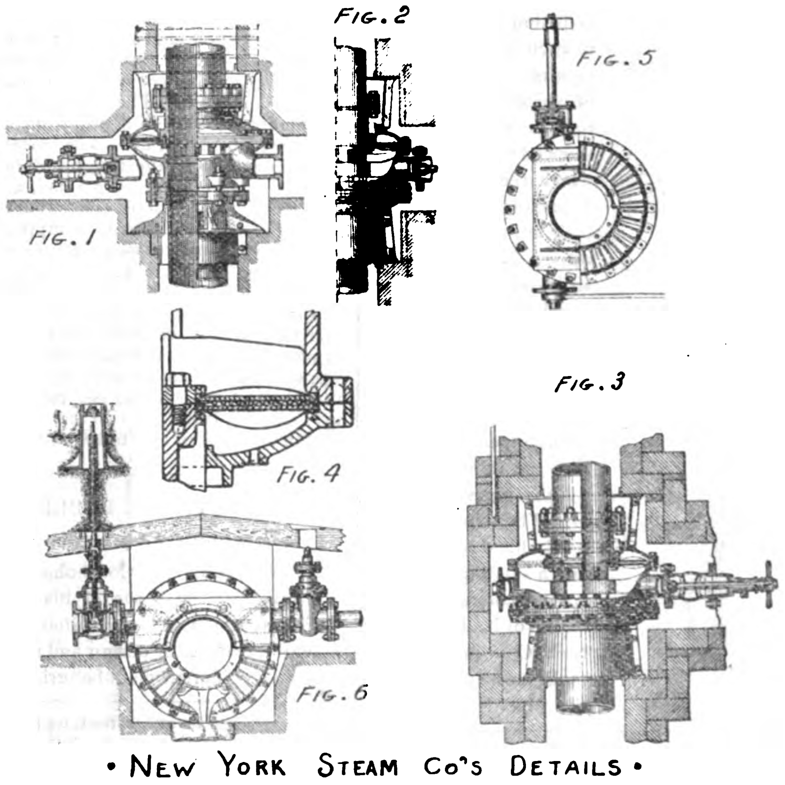
In carrying into practice the system of district steam distribution, as followed by the New York Steam Company, it was seen at an early date that the use of slip joints or stuffing boxes on underground steam pipes could not be tolerated in a crowded city, particularly at the high pressure proposed, on account of leakage and the numerous manholes required for access. Efforts were, therefore, made to develop a practicable expansion joint on the diaphragm principle, which should have no leakage. Experiments were first made with annular plates, riveted together through spacing rings alternately at their inner and outer edges. Such joints, however, were so stiff that their operation in lines of piping would probably have strained the various necessary joints in the pipes themselves. The joints became less stiff as the thickness of the diaphragms was decreased, and improvement was further made by corrugating the plates annularly, but still such joints were not satisfactory, and it was resolved to adopt diaphragms so thin as to require support to prevent rupture.

The expansion joint finally designed by Chas. E. Emery, which has been used successfully in all the work of the NewYork Steam Company, is shown in the six accompanying engravings. The joints, as described by Mr. C. E. Emery before several engineering societies, were, at an early date, called "variators," as they allowed for variation in the lengths of the pipes, and they are now generally known by this name. The single variator (Fig. 1), has but one diaphragm, the center of which is connected to the pipe by a clamp ring on a flanged sleeve, and the outer part of which is clamped between a covering plate and a bell-shaped piece diminishing to the size of the pipe, and provided with the female portion of a ball joint. The double variator has two similar diaphragms connected by a cylindrical-flanged body (Fig. 2). The outlets for consumers are taken from the variator bodies, as shown. A section of a diaphragm is illustrated in Fig. 3. The diaphragms are of sheet copper only, .04-inch thick, corrugated annularly. The inner and outer portions of the diaphragm are flat and make the joint by being clamped between the metal surfaces. The diaphragms are supported on radial plates ribbed on the back, and provided with projecting beads on their ends, resting on ledges in the castings. The supporting plates on the side towards the atmosphere are provided with heavier ribs to receive the full pressure of the steam, but plates with lighter ribs are also inserted on the other side to provide for the accidental occurrence of a vacuum in the pipes.

Each plate, therefore, forms a bridge from the inner to the outer ring, and supports the diaphragm on the corrugations. The radial length of the plates is 6 inches for all sizes of pipe. Provision is made for a movement of from 1¼ to 1½ inches for each diaphragm, but it is generally a little less in practice. As a rule, one diaphragm is provided for each 50-foot length of pipe. The greater part of the movement necessarily takes place without pressure while the pipes are being heated to 212 degrees. In regular operation the movement is only that due to the variation of temperature arising from slight changes of the working pressure, and under such circumstances the flexure is claimed to be well within the limits of elasticity of the metal. It is stated that only one of the large number of these expansion joints has ever been taken out on account of the cracking of the copper.

It may be of interest to add here that in discussing a paper on "The Distribution of Steam," presented by Mr. Emery before the British Institution of Civil Engineers, the suggestion was made to allow for expansion of the pipes by forming spring or expansion bends. In response to this Mr. Emery explained that such a system was impracticable in a street. Such a system would necessarily be underneath all other systems of pipes, and would prevent the user of any other pipes at that level for the entire width of the street. The method of offsets is commonly used by the New York Steam Company for small connections, and sometimes drainage is secured, when vertical offsets are necessary, by means of a yoke, one branch being run down under an obstruction, and carrying the water of condensation, while another is run up over the obstruction to carry the steam.

The largest pipe made with bends in the United States is, according to Mr. Emery, at Manchester, N. H., where, in making additions to the steam plant of a mill, the boilers had to be placed on one side of a canal and the engines on the other. The pipe was carried down one bank to a bridge across the canal, and back along the other bank to the engines, the offsets providing properly for expansion.



• NEW YORK STEAM CO'S DETAILS •

FIRE APPARATUS IN MILLS.

C. J. H. Woodbury, of Boston, in a paper on "Methods of Reducing the Fire Loss," read at a meeting of the American Society of Mechanical Engineers, devotes an interesting section to fire apparatus in mills. In this he says:

All methods for the prevention of fires fall so short of the ideal of immunity that there is a necessity for fire apparatus. The principle of defense of a manufactory against fire is that of self-protection by making the installation and management of the fire apparatus of such a grade as to be able to cope with the progress of any fire which can possibly occur.

Buckets of water are the most effectual fire apparatus. They should be kept full and distributed in liberal profusion in the various rooms of a mill, being placed on shelves or hung on hooks, as circumstances may require. In order to assist in keeping them for fire purposes only, they should be different from other pails used about the premises, and in some instances, each pail and the wall or column behind its position bear the same number.

It is a mistake to keep fire pails in dry rooms, as the water in the pails evaporates rapidly, and also in so doing interferes with the drying processes. The pails should be placed in some convenient situation near to the dry-room, where they will not oppose the drying process, and will also be more accessible in case of fire than when hung inside of a dry-room.

In unheated buildings the contents of fire pails can be prevented from freezing in winter by adding chloride of magnesium to the water.

Galvanized iron pails are better than wood pails, and indurated fibre makes a very satisfactory pail, especially in places around bleacheries, chemical pulp, or paper mills, where corrosive fumes rapidly injure metal pails.

There are various expedients to insure the full condition of fire pails, such as various floats, or electrical contrivances, or sealing over the top of the pail some thin sheet of impervious material; but the fact is that there is no fire apparatus so simple and effective as a full pail of water in good hands. All automatic devices are not above contingencies, and they lead to lowering the standard of personal espionage, which is the controlling principle in the administration of affairs.

Generally there is also need of casks of water to furnish a further supply to the fire-pails. Garden hose attached to a supply of water often constitute a very useful portion of the fire apparatus. Any cocks in the nozzles should be fixed in an open position by striking a heavy blow on the handle of the plug cock commonly used in such fittings.

Automatic sprinklers have proved to be a most valuable form of fire apparatus, operating with great efficiency at fires where their action was unaided by other fire apparatus, particularly at night. In mill fires the average loss for an experience of twelve years shows that in those fires where automatic sprinklers formed a part of the apparatus operating upon the fire the average loss amounted to only one-nineteenth of the averages of all other losses. If the difference between these two averages represents the amount saved by the operation of automatic sprinklers, then the total damage from the number of fires in places in which automatic sprinklers are accredited as forming a portion of the apparatus, has been reduced six and a quarter million dollars by the operation of this valuable device.

In an automatic sprinkler system, the sprinkler heads are attached to tees in pipes against the ceiling; the arrangement being such that there shall be at least a sprinkler to every one hundred feet of floor, some places requiring a still larger number of sprinklers. There should be two sources of water supply, with check valves in the pipes leading into the sprinkler system, giving it the benefit of the greater pressure without the intervention of any personal act. If one of these supplies is furnished by an elevated tank, the minimum head from the bottom of the tank to the highest sprinkler should be not less than twelve feet.

The inability to withstand freezing temperatures is a defect in automatic sprinkler systems which has not been fully remedied by invention. There are many so-called dry-pipe systems, in which the water is kept from the system until fire occurs, when the heat which releases the sprinkler is presumed to actuate devices which open the main valves admitting water to the system. Such apparatus is always complicated; these systems have sometimes proved to be inoperative at fires; and have frequently been discovered to be out of order when examined. The attempts at making a solution of low-freezing point, which should be non-combustible, and under the conditions of its use should also be non corrosive, do not appear to have been successful.

Water is sometimes removed from automatic sprinkler systems during cold weather by pumping in air to a pressure sufficient to displace the water. This method demands a great deal of attention; and in case of a fire it requires even longer to discharge the compressed air from the pipes and throw water on the fire than would be the case with the usual dry-pipe system.

The only resource for automatic sprinklers in rooms liable to temperatures below the freezing point appears to be to shut the supply-valve and slowly draw the water from the pipes late in the autumn and to admit the water in the spring. The valves should be in a place accessible at time of fire, and all persons liable to have any duties in the matter should be made acquainted with the necessity of opening such valves in time of fire.

When automatic sprinklers were first introduced there were many apprehensions that leakage, and also excessive water discharged upon small fires, would be sources of danger. Many automatic sprinklers have been made in such a manner as to impose unusual stress upon the fusible solder, which is a weak alloy ill adapted to withstand the forces due to water pressure, water hammer, and what is sometimes greater than either, the initial tension in setting up the sprinkler to make it tight. It is not surprising that such sprinklers break or leak; but among the score or more automatic sprinklers on sale it is easy to select several varieties, any one of which would impose but little risk of leakage from water pressure. The logic of figures show that this liability to damage is merely nominal in the case of well constructed sprinklers.

Although automatic sprinklers have proved to be so reliable and effective, yet, in order to provide for all possible contingencies, their introduction should not displace other forms of fire apparatus, particularly stand-pipes in the stairway towers with hydrants at each story. The hose at these hydrants should be festooned on a row of pins, or doubled on some of the reels made especially for such purposes. Stand-pipes are not recommended to be placed in rooms or on fire escapes; and inside hydrants should not be attached to the vertical pipes supplying automatic sprinklers.

Fire pumps are generally too small for the work required of them, 500 gallons per minute being the minimum capacity recommended. For a five-story mill there should be an allowance of 250 gallons per minute for an effective fire stream through a 1⅛-inch nozzle, and for lower buildings the estimate should rarely be less than 200 gallons for each stream

For stand-pipes ⅞-inch nozzles are recommended, but for yard hydrant service the diameter should never be less than 1-inch, and 1⅛. inch generally fulfills the conditions of best service.

It is important that the couplings on the hose and hydrants should fit those of the public fire department. The best diameter of hose is 2½ inches.

Pumps should be placed where they will be accessible under all circumstances; and so connected that they can be started at least once a week. They should be equipped with a relief valve, and also a pressure gauge.

Water mains about a mill yard should be of ample capacity not to cause an excessive loss by friction, their diameter being based upon a limit of velocity of ten feet per second for the maximum delivery.

The yard hydrants should be placed at a distance of 50 feet from buildings, and covered with a house which should also contain hose, nozzles, axes, bars, and spanners. Hydrant houses are made in a great variety of forms, but it is important that the doors should be high enough to avoid ice, or that the house should be placed upon slight mounds. An economical hydrant house may be built six feet square, with two adjacent sides hung on hinges, so that the doors can be swung around to the other side and be held by catches. The pins on which hose is hung should be two inches in diameter, and placed diagonally and staggered in two rows. If there is no hose cart, the reserve hose can be placed on shelves.

Stop valves in the mains should be covered by boxes four feet in height, and the direction of opening clearly marked on the hand wheel of the gate.

SIZE OF VENTILATING FLUE.

William Jennings, Harrisburg, Pa., writes: "We have an opera house which we desire to ventilate. It has a ground floor, first and second galleries. Our idea is to put in a flue and take the foul air out at each of the three floors. What we desire to know is, shall the flue be of uniform size, or increase at each floor? If so, in what ratio, and in what part of the flue shall the coil of steam pipes be placed?"

[Generally speaking, a ventilating flue or shaft, as in this case, must be larger than might at first be supposed in order to satisfactorily meet the requirements of successful operation. It is usually made of practically uniform size from the bottom up.

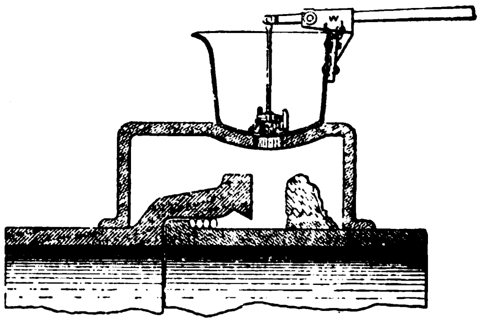
As to the location of the steam pipe coil in the shaft, it should be borne in mind that the aspirating power of the shaft depends on the height of the column of heated air as well as on the difference between the temperature in the shaft and that of the external air. It is, therefore, evident that the nearer the bottom of the shaft the heat is applied the greater will be the efficiency. The lowest point at which the coil is placed should, however, be above the entrance of the highest foul-air flue.]

LADLE FOR RUNNING LEAD JOINTS.

M. E., Jersey City, N. J., writes: "In looking over some odds and ends collected from various sources in past years, I happened upon the inclosed illustration of a combined melting pot and ladle for running lead joints in cast-iron pipes. It may be of interest to some of your practical readers engaged in pipe work.

The illustration represents a vertical section of the ladle and, at the same time, shows it mounted on a stool which is made to fit the pipe, thus simplifying the operation of casting.

It will be noticed that at the bottom of the ladle is a valve of cast-iron fitted with an asbestos face and operated by a vertical rod and pivoted lever. The latter is normally locked by a wedge W to keep the valve on its seat. When a joint is to be run the pot is placed over it and the valve is raised. The hot metal immediately flows past the valve into the joint, the light scum remaining on the surface, and the heavy dross, if there be any, lying in the bottom of the pot below the valve seat. For double joints, as in running collars on to two spigot ends, two valves are placed in the ladle at the proper distance apart for the two joints, and are raised together or separately. In case an explosion is feared from a damp joint, the handle may be lengthened by a piece of pipe, and the operator stand at a safe distance. The ladle was made by an English company in 12 sizes, varying in capacity, for single ladles, from ¼ cwt. to 3 cwt., and for double ladles from 1 cwt. to 4 cwt."



LADLE FOR RUNNING LEAD JOINTS.

[The ladle is substantially the same as that described in our issue of February 25, 1888, but the stool attachment was not shown there. We have, therefore, reproduced our correspondent's illustration. The ladle was made, and is probably still being turned out, by the Glenfield Company, Kilmarnock, Scotland.]

Novelties.

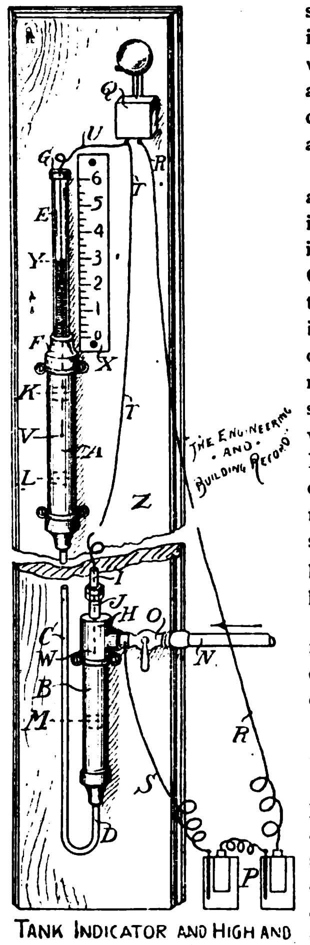
Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course, be understood that the selection does not imply indorsement.

BRACKEN'S TANK INDICATOR AND ALARM.

This device consists essentially of two 1-inch iron tubes A and B, each about 12 inches long,* connected by an ⅛-inch tube, whose leg C is 60 and D 3 inches long; the three tubes containing mercury arranged to show, by a multiplying index, the height of water in the tank, and also to close an electric circuit to operate high and low water alarms.



TANK INDICATOR AND HIGH AND LOW WATER ALARM

E is a flat glass tube, about 1 by ¼ by 10 inches, securely sealed into the tube A at F. G is simply a brass cap to exclude dust, etc. H is a tee, the upper end of which is reduced to receive the ¼-inch screwed tube J, through which the smaller tube I passes, and is vertically adjustable by jam nuts. X is a metal scale, adjustable on the panel Z that the apparatus is mounted on. When the indicator is first set up the stop-cock O is closed and enough mercury poured into the tubes to about fill the pipes B, C and D. The tube A is then partly filled with water and a small quantity of special colored oil put on top of it. If now the cock O is opened the tank pressure through the pipe N, added to the weight of mercury in the pipes B and D, will balance a larger mercury column in the pipes A and C, and a variation of one foot in the tank will cause a variation of about one inch in the top of the mercury column in the pipe A.

The apparatus is set so that when the tank water is at the lowest point the mercury will reach from W in the tube B to a point just above the bottom of the tube A. When the tank water is at the highest point the mercury will be forced down nearly to the foot of the tube B, and will rise to the point V in the tube A. For an intermediate stage the surfaces of the mercury would be at M and L, and the top of the water cushion at K and the top of the index column at Y, as shown in the illustration.

The column of water, K L, is only for filling to save mercury and separate it from the oil. When the mercury rises in the tube A it forces a certain quantity of oil up into the pipe E, and as the section of E is only about one-third that of A the oil must rise three inches for every inch the mercury rises,* thus multiplying the small variations of the mercury to a convenient size for reading. By varying the size of either the tube A or E any required length of gauge can be easily secured.

A gong Q, and electric battery P, are arranged to ring an alarm whenever high or low water is reached in the tank. One pole of the battery is connected to the gong by the wire R, and the other pole is connected to the indicator by the wire S. The gong is also connected to the indicator by wires T and U, but these wires can only be connected with S, so as to complete the circuit, when one or the other of them is in contact with the mercury. At low water the mercury rises to W in the tube B, the circuit is completed through the wire T, and the gong rings. As soon as the tank begins to fill the mercury falls in the tube B, breaking the contact at W, and stopping the gong. At the same time it rises in the tube A until, at high water, it makes a contact with wire U at V, completes the circuit through U, and the gong rings. Of course, the points V and W may readily be changed in position so as to make the alarm sound for any water levels.

This indicator is simple and direct, and is claimed to be economical and satisfactory. It was invented by W. R. Bracken, and is manufactured by Moody & Bracken, New York City.

THE SEVEN WELLS WATER-WORKS OF MADRAS.

Some portion of the town of Madras, Fort St. George, and almost every Military Institution in the Presidency town, India, was supplied for nearly a century with water of a remarkably good quality obtained from wells in a certain inclosure within the precincts of the northern limits of the city. This source of supply, says *Indian Engineering*, is well known as the "Seven Wells," and seems to depend on a bed of fine quartzose sand several miles in length (from north to south), but only 300 or 400 yards in width, its depth varying from 1 to 15 feet. The purity and wholesomeness of the water seems to depend on its being filtered through this stratum of sand, which, in some places, is covered to a considerable depth with red clay and sand. The so-called "Seven Wells" are ten in number, varying in depth from 20 to 30 feet, and are all 16 feet in diameter. The wells have never at any time shown the smallest signs of failure. Their present capacity is 140,000 gallons a day, and it is estimated that they can discharge three times that quantity should occasion arise. This estimate is supported by an old record, which says that two wells alone, when the others were choked up, have been known to yield 264,000 gallons in 24 hours. The water is lifted by *picottah*. This machine is a modification of the beam and bucket of Upper India and Bengal. It consists of a balance lever, weighted at one end, and a vertical rod and bucket at the other—worked by a man or men walking on the lever. The useful effect is about 90 per cent. It is well adapted for lifts ranging from 10 to 20 feet. The water is distributed within a radius of two miles and is conveyed in cast-iron pipes.

TRADE PUBLICATIONS.

WOOD'S WATER-TUBE STEAM BOILER.

John Wood, Jr., Conshohocken, Pa., has issued an attractive new catalogue of his water-tube safety boiler. It is fully illustrated, the various engravings showing the essential features of design and representing Wood boilers erected at different manufacturing establishments.

---

* Dimensions given are suitable for a tank elevation of about 60 feet above the indicator.

* This is approximately correct, for the weight of the oil is so insignificant that it hardly affects the hydrostatic balance of the mercury column.

THE ELECTRIC LIGHTING OF FRANKFORT-ON-THE-MAIN, GERMANY.

A joint report addressed by Professor Galileo Ferraris, Dr. Kittler, W. H. Lindley, F. Upperborn, and Dr. H. F. Weber, to the Mayor of Frankfort, on the various proposals for a central electric lighting station for that city, was recently published in the *Elektrotechnische Zeitschrift*. From an abstract of it, given in the pamphlet of foreign abstracts of the British Institution of Civil Engineers, the following is reprinted:

The commission of experts was instructed to report upon (1) the comparative merits of direct and alternate current supply; (2) the question of safety, general applicability of supply and cost of working; (3) the best system to be adopted. The various points on which the Commission was asked to pronounce an opinion were stated in the form of questions, and those questions coming under the headings (1) and (2), were as far as possible experimentally investigated, and the answers given unanimously. As regards heading (3), the commission did not give a joint opinion, but the members reserved to themselves the right to give their individual opinions if the town authorities should desire this. The joint opinions are grouped as follows:

Danger.—With the apparatus properly installed and carefully handled there is no danger to members of the staff. With careless handling the danger is the same, whether the current be 2,000 volts alternating or 2,000 volts direct. The transformers are to be placed in substations, and only the 100-volt currents taken into the houses of subscribers. There is thus absolutely no danger for subscribers. By proper safety-devices it is also possible to avoid all danger with the Siemens 5 wire system, which requires 500 volts direct currents.

Alternate Current Motors.—A 25 horse-power and a 5 horse-power Ganz motor were tested. The efficiency of the larger machine varied between 82 and 83 per cent., the power varying between 15 and 35 horse-power. The smaller machine gave 78 per cent. when loaded to 5 horse-power, and when the load varied between 3 and 8 horse-power the efficiency varied between 60 and 80 per cent. There is thus only a very small difference in the efficiency between the alternate and direct current motor, and in this respect both may be considered equally applicable. The alternate current motors must be started by hand and without load, the time occupied until they work normally ranging from 30 to 45 seconds. They cannot be so safely overloaded as direct current motors. The large motors showed during starting considerable development of sparks at the commutator, the length of sparks reaching 2 inches, whilst at each start about 17 milligrams of copper were wasted from brushes and commutators. This waste is not considered to be serious, neither is the fire risk consequent upon sparking of importance. The large motor worked somewhat noisily, but the smaller motors worked sufficiently quiet for domestic use. The large motor could be gradually overloaded to 40 horse-power, or by 60 per cent. of its normal power without losing its synchronism; with a load of more than 40 horse-power, even if gradually applied, the motor pulled up. Loads up to 26 horse-power could be suddenly applied and removed without loss of speed, but a load of over 26 horse-power, suddenly applied, caused the motor to stop. In view of this behavior the commission recommends that the nominal power of the motors chosen should exceed the normal power required in each case.

Alternate Current Transformers.—The efficiency of medium size transformers was found to be from 95 to 96 per cent. at full load; 93 to 94 per cent. at half load; 90 per cent. at quarter load, and from 80 to 82 per cent. at one-eighth load. Full load has been taken as that load at which no part of the apparatus reaches a temperature higher than 80° Cent. above that of the room. To increase the average efficiency of the whole system, the commission recommends the employment of transformer substations provided with automatic apparatus for varying the number of transformers at work in each group. Such an apparatus, costing about £7, has been submitted by Messrs. Ganz & Co., and found to work safely and without sparking. The firm offers to maintain the transformers in consideration of an annual payment of 6 per cent. of their cost price.

Arc Lamps.—Alternate and direct-current arc lamps were compared, and it was found that with equal energies (including the loss in resistances required for parallel working of direct current lamps) the illumination was as 4 to 5, showing a gain of 20 per cent. in favor of the direct-current lamp. Three alternate current lamps could be run in series from a 105-volt circuit. The consumption of carbon in an alternate-current lamp exceeds that in a direct current lamp requiring the same energy by about 20 per cent.

Direct Current Transformers.—The commission is not aware that such machines have yet been practically used. The proposal to wind the primary and secondary circuits upon the same armature core must be rejected as unsafe, but there is no reason to doubt that transformers with two distinct armatures will work satisfactorily and safely. The efficiency of 82 per cent. estimated by Messrs. Schuckert & Co., in their project is attainable at or near full load.

Storage Batteries.—On this subject the commission could not agree, and the members therefore gave their opinions individually. Ferraris pronounces against them. Weber, whilst dissatisfied with their efficiency, thinks their life satisfactory, and leans to their adoption in Frankfort under the maker's guarantee. Upperborn is in favor of storage batteries, as is also Kittler, who has especially a good opinion of the "Tudor" accumulator.

Five-Wire System.—The commission rejected the five-wire project previously offered by Messrs. Siemens and Halske, but thinks the new project a considerable improvement. It has, however, not yet been practically used. Regulation and balance between the wires is obtained by small dynamos erected in nine sub-stations throughout the town. The commission objects to the complicated nature of the project which requires the laying of five wires on each side of the streets.

CONTROLLING BACK-WATER FROM SEWERS IN BUILDINGS.

In a paper on preventing back water from sewers entering buildings during rain storms, read at the Master Plumbers' recent meeting at Denver, J. P. Gallagher, of St. Louis, Mo., said: "There have been many devices invented and patented in the way of automatic back-water valves that are said to overcome the trouble. These valves are usually placed in the house drain, out of sight, and in many cases out of reach, making it very difficult to make an examination of the device after it is put in position. Much depends upon the manner in which these valves are used.

"There are other ways in which back sewer-water may be prevented from entering buildings. One way is certain to work well at all times and under all circumstances, which is to have a separate system of drainage for the storm water from that of the house drainage. This method is, of course, expensive in the first construction of the system, but it avoids all trouble from back sewerage for all times. Another way to prevent back-water from sewers damaging buildings, where the separate system of sewerage does not exist, is to use heavy iron pipe of the proper size, laid from the main sewer in the street through under the cellar bottom to the rear of the building; there run a stand-pipe of the same material to a point a few feet above the level of the street manhole. The iron drain pipe, to be lasting, should be of special extra strong, and all joints should be calked with the same care that street mains are calked. Never leave a possibility or a doubt in your mind that a joint could be defective; place in your drain at proper distances handholes with Y branches and brass screws; calk therein and place in such a position that if any stoppage should occur a wire rope could be inserted for the purpose of cleansing, with but little trouble, at any point the stoppage may occur.

"I would not recommend the common stone pipe to be used in any locality where back-water is liable to give trouble, as I do not believe that a perfect job could be made with that kind of material; and, in addition to what I have already said, I would recommend for basements, where sinks and laundry tubs are placed, a valve to be placed under each fixture, with a rubber ball, which would immediately close up the aperture of the waste pipe or water-closet in the basement the moment the drain had any back pressure applied."

The pumping engines of Parkersburg, W. Va., broke down some days ago and the city was left without a water supply. All manufacturing stopped, and water for domestic use was carted from the Ohio River.

ARCHITECTURAL COMPETITIONS.

Trenton, N. J.—Normal School.—Plans are wanted, no date specified, for a normal school building at this place. Cost, $35,000. Address the Sub-Committee on Normal School, as above.

CONTRACTING INTELLIGENCE.

For works for which proposals are requested see also the "Proposal Columns," pages i-ii-x-xi.

WATER.

For Additional Water Items see Proposal Columns

Milwaukee, Wis.—The following bids for furnishing 850 pieces of iron water-pipe were received by the Board of Public Works July 14: Dennis Long & Co., Louisville, Ky., $30.00, $24,600; R. D. Wood & Co., Philadelphia, $30.90, $25,338; Howard Harrison Iron Co., Cincinnati, $32.50, $26,650; Addyston Pipe and Steel Co., Covington, Ky., $28.45, $23,329. The contract was awarded to the Addyston Pipe and Steel Co.

For dredging a trench for laying two lines of cast-iron pipe from the crib end of the proposed tunnel to a point 5,000 feet east: C. H. Starke, Milwaukee, $13 per foot, $65,000; F. M. Knapp, Racine, Wis., $70,000. Contract awarded to C. H. Starke.

Laying the pipe: Thacher & Breyman, Toledo, O., $6 per foot, $30,000; John O'Neill, Milwaukee, $5.74, $28,700. No award made.

Salt Lake City, Utah.—At the session of the City Council, held July 8, the following bids were received for the construction of a brick conduit for water-works, quantities being: Earth excavation and backfilling, 78,000 cubic yards; earth embankment, 5,000; rock excavation, 2,000; cut stone masonry, 10; brick masonry, 11,000; concrete, 250, tunneling in rock, 300. Regan & Delany, Omaha, $112,647.00; J. F. Riley & Co., Denver, $140,995.00; Houlahan & Griffith; Pasadena, Cal., $149,268.67; J. S. Morse & Co., Salt Lake City, $149,522.00; Macdonald & D'Kay, San Bernardina, Cal., $181,620.50. The bids were all rejected, as sheet-iron pipe was substituted for all brick work.

Dayton, Wash.—The people of this place propose bonding the city for $55,000, for a system of water-works.

Astoria, Ore.—It is reported that a Chicago company will purchase a controlling interest in the local water-works plant. Improvements will be made costing from $100,000 to $150,000.

Lancaster, N. Y.—The Water Committee of the City Councils has selected a site upon which to erect the projected reservoir, and operations will begin at once.

Marysville, O.—A franchise to establish and operate a water-works plant at this place has been granted to Walter Fullington.

Lincoln, Neb.—The Lincoln Water Company will lay four miles of mains, put in 50 additional hydrants, and establish a filtering system.

Silver City, Neb.—The people of this place are discussing the water-works question.

Portland, Ore.—The Highland Park Water Company has been incorporated at this place, and a system of water-works will be established. Address E. E. Miller, as above, for particulars.

Cheney, Wash.—The water-works system at this place has been purchased by a concern with James Steel at its head, and extensive improvements will soon be made. Address the above person at this city.

Rochester, N. Y.—Engineers Tubbs and Rafter have prepared a report on additional water supply, in accordance with the instructions of the Executive Board. The immediate use of the Gates well is advised and the Board is also recommended to sink one or two wells west of the Gates well in places where there seems best prospects of striking water. The report will be formally presented to the Executive Board on July 21. The Board has advertised for sealed bids for a pumping plant with a capacity of 2,000,000 gallons a day. For complete particulars see our Proposal Columns.

Pulaski, Va.—A water-works system is proposed for this place. Information can be had of J. H. Dingee, Secretary Virginia Investment Association, 330 Walnut Street, Philadelphia, Pa.

Contracting News Department.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

WATER.

(For Additional Items, see page 109.)

CINCINNATI, O. — Numerous new water mains have been ordered by the City Council.

HARRIMAN, TENN.—M. M. Tidd, C. E., of Boston, has made report on a water-works system for this place, which contemplates a pumping plant of 6,000,000 gallons and a reservoir. A report on a sewerage system is in process of preparation. Gen. Clinton B. Fiske, of New York, was president of the Land Company, which is largely interested in the projected improvements.

MANCHESTER, N. H.—M. M. Tidd, C. E., of Boston, is making plans for a high service system of water-works for the city, involving pumping plant and reservoir and additional mains.

CHADRON, NEB.—The City Clerk here writes: "I think there is very little probability of any extension of our system in the next year or so."

MORGANTON, N. C.—T. I. Gillam, Secretary of the Board of Water Commissioners, writes: "The city of Morganton has contracted with the Morganton Water Supply and Transfer Company for water. They will put in a plant that will furnish about 2,000,000 gallons per day of 24 hours. There will be no machinery. The water will be supplied by gravity. S. R. Collett, of Morganton, will have charge."

NORFOLK, VA.—An extended water-works system is proposed for this place. Information can be had of J. H. Dingee, Secretary Virginia Investment Association, 330 Walnut Street, Philadelphia, Pa.

NORTON, VA.—A water-works system is proposed for this place. Information can be had of J. H. Dingee, Secretary Virginia Investment Association, 330 Walnut Street, Philadelphia, Pa.

CEREDO, W. VA.—A water-works system is proposed for this place. Information can be had of J. H. Dingee, Secretary Virginia Investment Association, 330 Walnut Street, Philadelphia, Pa.

WATER-WORKS.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Niagara Falls, N Y.; Watkins, N. Y.; Washington, D. C.; Hinton, W. Va.; Huntington, Ind.; Fort Keogh, Mont.; Muskegon, Mich.; Rochester, N. Y.; Springfield, Mass.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

GALION, O.—About 9,000 feet of pipe sewers will be constructed in this place. See the Proposal Columns for further information.

GRAND FORK, N. D.—A special city election resulted in carrying proposition to bond the city for sewers for $50,000.

SEWERS.—See our Proposal Columns for information regarding sewers and sewer construction at the following places: Athens, Ga.; Gloversville, N. Y.; Fremont, O.; New Haven, Conn.; Trenton, N. J.; Detroit, Mich.; Gravesend, L. I.; Cleveland, O.; Key West, Fla.; Para, Brazil; District of Columbia; Boston, Mass.; Gardner, Mass.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns

ROCHESTER, N. Y.—The Common Council has taken the first steps towards replacing the Court Street bridge with a new structure. The estimated cost of the new bridge is $160,000.

AUSTIN, TEX.—A charter was filed here July 12 for the Continental Bridge Co., of Cameron County, Tex. The capital stock is $1,000,000, and its object is to bridge the Rio Grande from near Brownsville, Tex., to or near Matamoras, for railroad trains and other transit, at the option of the corporation. Felician San Roman, of Brownsville, is president.

SEATTLE, WASH.—The following bids for the erection of a bridge over Green River were received by the Kings County Commissioners, July 7: Fred. Brooks, Seattle, 100 foot span, piles for piers driven, $594; Clinton West, Seattle, $775; Harlan & Mattall, Seattle, $850; F. P. George, Seattle, $875.

TORONTO, CANADA.—At a meeting of the Board of Public Works held July 9, the draft was submitted of a proposed agreement between the city and the railways, under which it is intended to substitute for the present wooden bridges on the line of Dundas Street an iron and steel structure costing $55,000, of which the Grand Trunk will contribute $11,000 and the Canadian Pacific, $9,000.

WILLIMANSETT, MASS.—The County Commissioners are having plans prepared by the engineer, Edward S. Shaw, of Boston, for the masonry and superstructure for a new iron bridge across the Connecticut River between Holyoke and Chicopee.

WINONA, MINN.—The contract for the construction of the new railway bridge has been let to the Union Bridge Co., of New York, work to be commenced March 1, 1891. The bridge will be used jointly by the Green Bay, Winona & St. Peter, Chicago, Burlington & Northern and the Winona & Southwestern Railway Companies.

CINCINNATI, O.—There is a project to reconstruct the McMillan Street bridge, at an estimated cost of $35,000.

WHEELING, W. Va.—The date of opening the bids for the construction of a stone bridge at this place has been postponed from July 21 to July 28. See our Proposal Columns.

DULUTH, MINN.—The City Council has decided to build a bridge over the ship canal at this place. The Hon. W. W. Billson will furnish particulars.

BIRMINGHAM, ALA.—The Smith Bridge Co., of Toledo, O., has been awarded the contract for the bridge at Twenty-first Street in Birmingham. The followings bids were received: Southern Bridge Co., superstructure, $35,846; substructure, $1,650. Milwaukee Bridge & Iron Co., superstructure and substructure, plan No. 1, $36,577; plan No. 2, $37,977. Smith Bridge Co., superstructure, $40,000; substructure, no bid. Edgewood Bridge Works, superstructure, $40,695; substructure, no bid. Chicago Bridge & Iron Works, superstructure, $43,698; substructure, no bid. Shiffler Bridge & Iron Works, superstructure, $50,500; substructure, no bid. The Southern Bridge Co. withdrew its bid and the plans of the Milwaukee Bridge & Iron Co. were not accepted.

FAIRHAVEN, WASH.—The Detroit Bridge & Iron Co., of Detroit, has been awarded the contract for building a single-track iron drawbridge for the Fairhaven & Southern Road over the Nooksack River, near here. The bridge has a weight of 335,000 pounds. Four bids were received, the contract for the iron work being awarded at 4¼ cents a pound f. o. b., Chicago.

CHICAGO, ILL.—The Kenwood Bridge Co. has been incorporated here to manufacture and sell iron and steel bridges; capital, $100,000; incorporators, F. W. Baker, Paul Willis and others.

BRIDGES.—See our Proposal Columns for information regording bridge construction at the following places: Boston, Mass.; Wheeling, W. Va.; Marietta, Ga.; Toledo, Wash.

GAS AND ELECTRIC-LIGHTING.

TRENTON, MO.—The Trenton Thomson-Houston Electric Company has been incorporated here, with a capital stock of $10,000. Incorporators, James Anderson, Robert M. Cook, and others.

MILLVALE, N. J.—This place is to have an electric lighting plant.

LAURENCE, N. Y.—The Committee on Streets has been authorized to contract for the lighting of the streets of that city, for a period not to exceed three years, beginning October 1, 1890.

LAS VEGAS, N. M.—A plant is to be established at this place by the Las Vegas Electric Light Company. About $100,000 will be the outlay. T. B. Catron will furnish details.

KANSAS CITY, MO.—Improvements will probably be made to the plant of the Gate City Electric Company.

SANGER, CAL.—This place is to have electric lights.

INDEPENDENCE, ORE.—The people of this place have decided in favor of establishing an electric light plant.

AMSTERDAM, N. Y.—The people of this place have decided in favor of electric lights and a plant will be established here at once.

TAMPA, FLA.—The Florida Electric Co. has been incorporated here and a plant will be established. J. R. Ritter can furnish particulars.

TECUMSEH, MICH.—An electric light plant is to be established at this place by the Tecumseh Electric Co., at an estimated cost of $50,000.

MORRISON, ILL.—An electric light plant is to be established at this place.

SLATER, MO.—Bonds in the sum of $7,750 have been voted here for the purpose of establishing an electric lighting plant.

WAKEFIELD, MASS.—The people of this place have decided in favor of electric light and a plant will be established by the Citizens' Gas Co.

SEATTLE, WASH.—The Seattle Electric Light Co. has been incorporated and will establish a plant at this place, to cost $500,000. J. H. McGraw will furnish particulars.

PASSAIC, N. J.—The Passaic Electric Light Company will increase the facilities of its plant and add new machinery. Two engines, 125 horse-power and 100 horse-power, 80 horse-power generator and 1,300 lights are among the contemplated additions.

LAFAYETTE, IND.—The Lafayette Electrical Manufacturing Company has been incorporated here, and will expend $50,000 on a plant. The secretary is C. G. Longyear.

WAYCROSS, GA.—An electric light plant and gas works will be established and operated at this place by the Satilla Manufacturing Company For details address M. Albertson, as above.

BATESVILLE, ARK.—An electric light plant is to be established at this place by J. W. Hamilton and others.

MARYSVILLE, O.—This place is to have electric lights.

MILLERSBURG, O.—The Millersburg Electric Light Company will establish a plant at this place. For details address P. B. Chase, Secretary, Mount Vernon, O.

ELECTRIC RAILWAYS.—New electric railways will be established and improvements will be made to those already built at the following places: Hebranville, R. I.; Milwaukee, Wis.; Syracuse, N. Y.; Cairo, Ill.; Sedalia, Mo.; Aurora, Ill.

STREET-WORK AND PAVING.

TORONTO, CAN.—Considerable street paving is to be done in this city.

AKRON, O.—Main Street to be paved with brick, one half mile of paving.

PINE BLUFF, ARK.—The Commissioners of Paving District No. 1 of this city will receive bids soon for 6,000 square yards of vitrified brick pavement concrete foundation, etc. Fred. J. H. Rickon, Little Rock, Ark., is engineer of the district.

INDUSTRIAL.

C. A. Blessing, manufacturer and dealer in plumbing material, at Philadelphia, was partially burnt out on July 4, causing a temporary suspension of business. Mr. Blessing will open a new store at 625 Arch Street, Philadelphia, for the display of his sanitary specialties.

NEW YORK CENTRAL IRON WORKS CO.—W. B. Dunning has formed a stock company of $100,000 capital for the manufacture of his patent steam and hot water heaters. It will be known as the New York Central Iron Works Company. Mr. Dunning remains at the head of the new organization as President, and will be assisted by a full corps of practical men in each department. They will continue to manufacture engines and boilers of all kinds, as well as jobbing and repairing; also furnish iron and brass castings of all kinds. It is probable that the capacity of the works will be doubled, and a large amount of new machinery put in.

SALT LAKE CITY, UTAH.—Extensive bathing houses will be established at this place, to cost $300,000.

POTTSTOWN, PA.—Jas. Dunlap is about putting some new carpet making machinery into the old railroad carpenter shop to fit it up for a carpet works. There will be $30,000 to $40,000 worth of machines put in, he says.

GOVERNMENT WORK.

PROPOSALS.

(Continued from page x.)

HUNTINGTON, IND., WATER-WORKS.

SEALED PROPOSALS WILL BE RECEIVED until noon of TUESDAY, July 29, 1890, by The Water-Works Manufacturing Company, of Huntington, Ind., for the following items for the Huntington **WATER-WORKS**:

One thousand five hundred and seventy-seven (1,577) tons of cast-iron water pipe, ranging from four (4) to sixteen (16) inches diameter.

Sixty-two thousand two hundred and seventy-six (62,276) pounds of special castings.

Eighty-four (84) six (6) inch double nozzle fire hydrants.

Fifty (50) four (4) inch double nozzle fire hydrants.

Ninety-seven (97) stop valves, from four (4) to fourteen (14) inches diameter.

Ninety-seven (97) stop boxes for above valves.

Laying of above Pipe, and setting of above Special Castings, Fire Hydrants, Stop Valves and Stop Boxes.

One brick Pumping Station.

One brick-lined circular Pump Well.

One timber Intake Pier.

One or two systems of Driven Wells.

Two (2) compound duplex direct-acting pumping engines, each of one million five hundred thousand (1,500,000) gallons daily capacity, together with two (2) return tubular boilers, sheet-iron chimney and all appurtenances necessary to complete said machinery.

Proposals must be made on the blank forms furnished by The Water-Works Manufacturing Company, and all legal formalities must be complied with to secure consideration of the proposals.

Plans for above work may be examined and blank forms of proposal and specifications can be obtained at the office of the Water-Works Manufacturing Company, Huntington, Ind., or the office of the Consulting Engineer, rooms 21 and 22 Glenn Building, Cincinnati, O.

The proposals must be sealed and addressed to The Water-Works Manufacturing Company, Huntington, Ind., and be indorsed with the name of the person, firm or corporation which make the tender, and be accompanied by a certified check, payable to the order of the Treasurer of The Water-Works Manufacturing Company, as follows:

Water pipe and special castings	$500
Fire hydrants	300
Stop valves	300
Pipe laying	500
Pumping station	300
Pump well	100
Intake pier	200
Driven wells	250
Pumping machinery	500

The company reserves the right to reject any or all proposals.

THE WATER-WORKS MANUFACTURING COMPANY,
WILLIAM MCGREW, Pres't.
JOHN W. HILL, Consulting Engineer,
Cincinnati, O.
HUNTINGTON, IND., June 30, 1890.

PROPOSALS FOR CEMENT FOR THE DISTRICT of Columbia.—Office of the Commissioners. Washington, D. C., July 15, 1890.—Sealed proposals will be received at this office until 12 o'clock M., on TUESDAY, July 29, 1890, for furnishing **CEMENT** for the Public Works of the District of Columbia. Blank forms of proposals and specifications can be obtained at this office upon application therefor, together with all necessary information, and only bids upon these forms will be considered. The right is reserved to reject any and all bids, or parts of bids.

J. W. DOUGLASS,
L. G. HINE,
H. M. ROBERT,
Commissioners, D. C.
8

PROPOSALS FOR THE CONSTRUCTION OF Sewers.—Office of the Commissioners, Washington, D. C., July 14, 1890.—Sealed proposals will be received at this office until 12 o'clock M., on THURSDAY, July 31, 1890, for constructing in the District of Columbia, **TERRA COTTA PIPE SEWERS**, Brick Sewers and Receiving Basins. Blank forms of proposals and specifications can be obtained at this office upon application therefor, together with all necessary information, and only bids upon these forms will be considered. The right is reserved to reject any and all bids, or parts of bids.

J. W. DOUGLASS,
L. G. HINE,
H. M. ROBERT,
Commissioners, D. C.
8

JULY 15, 1890.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M., on the 8th day of August, 1890, for all the **LABOR AND MATERIALS** required for the extension of the U. S. Post-Office, etc., building at HOUSTON, TEXAS, in accordance with the drawings and specification, copies of which may be had on application at this office or the office of the Superintendent. Each bid must be accompanied by a certified check for $100. The Department will reject all bids received after the time fixed for opening the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be sealed and indorsed, "Proposal for the extension of the U. S. Post-Office, etc., building at Houston, Tex.," and addressed to JAS. H. WINDRIM, Supervising Architect. 8

PROPOSALS.

COMMONWEALTH OF MASSACHUSETTS.

Metropolitan Sewerage Commissioners.—Notice to Contractors.

SEALED BIDS FOR BUILDING SECTIONS 8 and 9 of the Metropolitan Sewerage System (East Boston) and Sections C and D (Brighton), all in the city of Boston, in accordance with the form of contract and specifications to be furnished by the Board of Metropolitan Sewerage Commissioners, will be received by said Board at its office, 93 Lincoln Street, Boston, Mass., until 12 o'clock M. of WEDNESDAY, August 13, 1890.

No bid will be received unless accompanied by a certified check for the sum of one thousand dollars.

All bids must be made upon the blank forms furnished by the Board.

The exteral diameter of the sewer on Sections 8 and 9 is from eleven to fifteen feet, and on Sections C and D is from six and one-half to nine feet.

Some other particulars are approximately as follows:

Section.	Length. Feet.	Average Depth. Feet.	Cub. yds. Brick Masonry.	Cub. yds. Concrete Masonry.	No. Piles.
8	4,100	15	1,800	4,900	40
9	3,700	14	2,000	4,000	40
C	5,800	15	1,500	2,600	1,000
D	5,400	16.5	1,600	2,400	100

Plans can be seen, and specifications and form of contract can be obtained at the above office.

Each bidder is required to make a statement indicating what sewer and similar work he has done, and to give references that will enable the Board to judge of his business standing.

The Board reserves the right to reject any and all bids.

HOSEA KINGMAN,
TILLY HAYNES,
ROBERT T. DAVIS,
Board of Metropolitan Sewerage Commissioners of Massachusetts.
HOWARD A. CARSON, Chief Engineer. 10

JULY 16, 1890.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M. on the 12th day of August, 1890, for furnishing all **LABOR AND MATERIAL** required for the erection and completion of the U. S. Court-House and Post-Office building at MONROE, LA. (except heating apparatus), including approaches, outhouses, etc., in accordance with the drawings and specifications, copies of which may be had at this office or the office of the Superintendent. Each bid must be accompanied by a certified check for $500. The Department will reject all bids received after the time fixed for opening the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be sealed and indorsed "Proposal for the Erection and Completion of the U. S. Court-House and Post-Office building at Monroe, La.," and addressed to JAS. H. WINDRIM, Supervising Architect. 8

JULY 10, 1890.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M. on the 6th day of August, 1890, for all the **LABOR AND MATERIALS** required in the erection and completion of the U. S. Post-Office building at LOWELL, MASS., (approaches and heating apparatus not included) in accordance with the drawings and specification copies of which may be had on application at this office or the office of the Superintendent. Each bid must be accompanied by a certified check for $500. The Department will reject all bids received after the time fixed for opening the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be sealed and indorsed "Proposals for the Erection and Completion (except Heating Apparatus and Approaches) of the U. S. Post-Office building at Lowell, Mass.," and addressed to JAS. H. WINDRIM, Supervising Architect. 7

TO CONTRACTORS AND BUILDERS.—Office of Lighthouse Engineer, 9th District, Detroit, Mich., July 7, 1890.—Sealed proposals will be received at this office until 4 o'clock P. M. of WEDNESDAY, the 30th of July, 1890, for furnishing the **MATERIAL AND LABOR** of all kinds necessary for the construction and erection of keeper's dwelling, wood shed, elevated walk, etc., required for Cedar River Light Station, Michigan. Plans, specifications, forms of proposals and other information may be obtained on application to this office. The right is reserved to reject any or all bids and to waive any defects. WILLIAM LUDLOW, Lighthouse Engineer.

PROPOSALS FOR SERVICE CONNECTIONS.—Office of Post Quartermaster, Fort Keogh, Mont., July 5, 1890. Sealed proposals in triplicate, subject to the usual conditions, will be received at this office until 12 o'clock noon, on the 5th day of August, 1890, and then opened, for furnishing all the labor required in making **SERVICE CONNECTIONS** with water mains at this post. Specifications, instructions to bidders, and blank forms of proposals will be furnished on application to this office. M. C. MARTIN, 1st Lieut. & R. Q. M. 22d Infantry; A. A. Q. M., U. S. A. 9

PROPOSALS.

OFFICE OF CHIEF QUARTERMASTER, Division of the Atlantic, Governor's Island, N. Y. H, July 12, 1890. Sealed proposals, in triplicate, subject to usual conditions, will be received here until 12 o'clock noon, August 12, 1890, and then opened for construction, at Governor's Island, N. Y. H., of one (1) double set of officers' quarters. All information can be obtained at the office of the undersigned. The Government reserves the right to reject any or all bids. Milwaukee av and Holburn st, br store and flats; cost, $35,000; o, M E Tabor; a, J E O Pridmore; b, J B Sweet.

197 California av, br flats; cost, $8,000; o, Mrs A C De Luce; a, J M Haskins; b, H Hughes.

114–16 Hoyne av, br factory; cost, $22,000; o, Peter Fahrrey; a, C A Weary; b, W D Price.

345–53 Michigan av, addn br story; cost, $8,000; o, Manual Training School; a, S S Bowan; b, Barney & Rodatz.

1077–79 W Harrison, br livery stable; cost, $10,000; o, Frank Warren; a, Edbrooke & Burnham; b, C & A Price.

270 Sedgwick, br store and flats; cost, $14,000; o, Mrs M A Smith; a, H Sierks; b, Rodgers & Koch.

1267–1317 W 12th, br foundry; cost, $150,000; o, Fraser & Chalmers; a, Raeder & Coffin.

3005 Indiana av, addn to church; cost, $20,000; o, Fifth Presbytertan Church; a, J T Long; b, W & S Nelson.

2968 Lake Park av, br dwell; cost, $14,000; o, O S Lyford; a, J J Egan; b, Slattery & Sons.

1552–62 Wilwaukee av, br store and flats; cost, $70,000; o, Mrs Marie Schueltler; a, H Sierks; b, O W Menke.

194–202 Van Buren, br store and flats; cost, $80,000; o, E J Monaghan; a, Lamson & Newman; b, Ed Lehman.

552 Halsted, br st, cost, $10,000; o, L Klein; a, Furst & Rudolph; b, T Nicholson.

119 Dearborn, additional stories; cost, 50,000; o, Mrs Mary Jones; a, Burnham & Root.

308 W Erie, br store and flats; cost, $10,000; o, Martin Olson; a, Lutken & Thieslen, b, A Nelson & Son.

3801–11 Prairie av, br dwells; cost, $35,000; o, E A Springer; a, Pond Bros; b, Hammond & Chapman.

866–70 W Madison, br store and flats; cost, $25,000; o, Judge M F Tuley; a, Wm Strippelman.

222–26 Campbell av, br flats; cost, $12,000; o and b, Chapman Bros; a, F B Townsend.

267 Franklin, br store and flats; cost, $15,000; o and b, H T Lundgren; a, Ostling Bros.

N California av nr Kinzie, br foundry; cost, $30,000; o, Griffen Wheel and Foundry Co; a, E Lee Heidreich.

177 buildings costing less than $7,000 each.

CHARLESTON, S. C.—Nothing over $7,000 in value to report.

CINCINNATI, O—N w cor Horton and Saffron sts, 2-story br church; cost, $11,500; o, St. Martin's Congregation; c, C F Meyers.

Miami Canal and Dodsworth st, 3 and 5-story br warehouse; cost, $10,000; o, Clifton Springs Distillery Co.; a, O H Meyers.

Langland st, Cumminsville, 1 story passenger station; cost, $7,000; c, Walker Branch.

4th and Race st, 7-story br addn to St. Nicholas Hotel; cost, $50,000; o, Carlisle Estate; a, A C Nash and H E Siter.

S e cor Wheeler and Warner st, 2½-story br dwell and ten; cost, $8,500; o, M Rothschild; a, G and A Brink.

Vine and Mulberry sts, 4-story br store and flat bldg; cost, $16,000; o, Louis F Ahlers; a, as above.

CLEVELAND, O. — Madison av, West Cleveland, br and s 8 room bldg; cost, $25,000; o, Board of Education, West Cleveland; a and b, not let.

COLUMBUS, O—Long st, s and br business block; cost, $30,000; o, M G Lilley Co.

Long st, shops, etc., cost, $13,000; o, same as above.

Long st, 7 dwells; cost, $19,200; o, same as above.

BUILDING INTELLIGENCE.

DENVER, COL.—Sherman av, bet 12th and 13th sts, br and stone dwell; cost, $15,000; o, W R Thompson; a, Varian & Sterner.

Union Depot prop., br and stone addition; cost, $30,000; o, Union Depot Co; a, same as above.

Highland st, pressed br dwell; cost, $8,000; o, E W Ray; a, same as above.

Capitol Hill, Roman br dwell; cost, $15,000; o, F Miller; a, same as above.

Arapahoe st, bet 21st and 22d sts, br store; cost, $8,000; o, F Garbarshy; a, same as above.

Lincoln av, bet 2d and 3d sts, br dwell; cost, $7,000; o, Geo K Speer.

DETROIT, MICH.—S w cor Trumbull and Alexandrine avs, 2½-story br and stone res; cost, $12,000; o, Wm Northwood; a, Geo E Depew; b, individual contracts.

N w cor Trumbull and Alexandrine avs, 2½-story br and stone res; cost, $10,000; o, Wm J Howard; a, same as above; b, not let.

S s Montcalm st, bet Antoine and Hastings sts, 5 2½ story br res; cost, $15,000; o, Theodore Gorenflo; a, P Dederichs, Jr; b, not let.

E s Mt Elliot and opposite Hendricks av, 2½-story br res and barn; cost, $7,000; o, G Burlage; a, same as above; b, not let.

Kanter, Hamlin and Baltimore avs, 41 2-story fr dwells; cost, $82,000; o, R M Baham.

151 E High st, 2-story br res; cost, $8,000; o, Dr F D Wheeler.

DULUTH, MINN.—Architects Palmer & Hall have prepared plans for the erection of a $250,000 high school building at this place.

FINDLAY, O.—White addition br school bldg; cost, $8 600; a, Wm Burge, Toledo, O; b, Brake & McMillan.

FORT WORTH, TEX.—Frank W. Kane, architect, is preparing plans for a brewery to cost $95,000; plans will be out in a few days. Also one large business house to cost $37,500.

GALVESTON, TEX.—Wharf front, warehouse, N Y & Texas Steamship Co; cost, $11,000; o, C H Mallory & Co; a, N J Clayton & Co; b, not let yet.

GROSSE POINTE, MICH.—2½ story fr and br res; cost, $7,000; o, John Villoran, Detroit; a, L M Smith & Son, Detroit; b, not let.

HOLYOKE, MASS—Br addition, 4 stories, 60x100; o, Connecticut River Paper Co; a, E A Ellsworth.

KNOXVILLE, TENN.—S B Luttrell has prepared plans for the erection of a $25,000 residence at this place.

MARSHALL, TEX.—A $10,000 church will be erected here. Address J B Carter, as above.

MILWAUKEE, WIS.—S e cor 14th and Vliet sts, stockhouse; cost, $5,000; o, Thos Given; a, Chas Kirchhoff; b, Hausmann Bros.

Eastwater and Huron sts, stockhouse; cost, $13,000; o, H Ludington; a, H C Koch & Co; b, A Wendt.

Cor Eastwater and Huron sts, stockhouse, cost, $65,000; o, D Adler; a, same as above, b, Kiesen Bros.

MINNEAPOLIS, MINN.—S e cor Main and Bank sts, 5-story br piano factory, cost, $50,000; o, Century Piano Co; a, A F Struch.

88–98 Central av, 3-story br stores and flats; cost, $20,000; o and b, A Gagnon; a, J H Record.

S Wash av, bet 10th and 11th avs, 2-story br stores and flats; cost, $13,000; o, J M Robertson; a, Orff Bros; b, Pike & Cook.

BUILDING INTELLIGENCE.

MINNEAPOLIS, MINN.—A police station, to cost $15,000, will be built at 35th st and 20th av.

1815 Kenwood boulevard, br dwell, cost, $8,000; o, C S Brockett; a, Geo Bertrand, b, J H McClay.

1101–3–5 n 20th av, br stores and flats; cost, $15,000; o, E B Hubbard; a, F B Hart; b, Seymour & Hart.

MT. CLEMENS, MICH. — A $150,000 hotel will be erected here. Address N J Gibbs, as above.

PEORIA, ILL.—Plans have been prepared for the erection of a $90,000 hotel at this place. Address Architect N J Gibbs, Mt Clemens, Mich.

PHILADELPHIA, PA. — Holmesburgh Junction, administration building; o, W R Dougherty.

PORTLAND, ORE.—Stone city hall; cost, $500,000; o, city of Portland; a, H J Hefty; b, not let.

READING, PA.—5th and Elm sts, 2-story Queen Anne bldg; cost, $10,000; o, A Hoff; a, Smith Bros.

5th and Exeter sts, 2-story s church; cost, $12,000; o, Rev Stoner.

SHOLES, IND.—M. Q. Wilson, architect, Louisville, Ky., has prepared plans for a hotel near here, to cost $30,000, also for another hotel in an Indiana town.

SOUTHERLAND, FLA.—A hotel will be erected here at a cost of $100,000. Address C T Taylor, Barker Block, Omaha, Neb.

ST. LOUIS, MO.—Vandeventer place and Grand av, addition to br dwell; cost, $7,000; o, Chas Clark; b, J W Givens.

Wabash and Boyle avs, br power house; cost, $15,000; o, Missouri R R Co; b, Milburn & Rich.

Easton and Ewing avs, br store and dwell; cost, $7,900; o, J A Scudder; b, same as above.

Rauschenbach av and Benton st, br dwell; cost, $8,000; o, F H Schlingman; b, H Schulte.

Clemens and Goodfellow avs, fr dwell; cost, $7,000; o, P A Wilcox; b, E Marlatt.

Cabanne and Goodfellow avs, fr dwell; cost, $9,000; o, Mary Hausman; b, sublet.

N w cor 2d st and Clark av, br store; cost, $30,000; o, M Forster; b, A H Haessler.

ST. PAUL, MINN.—Iglehart st, near Milton st; 7 fr dwells; cost, $17,150, o, John Elms.

Mound st, near Earl, 2-story br dwell; cost, $28,000; o, J F Eisemmenger.

Dayton st, near Kent st, 2-story br dwell; cost, $8,000; o, J W Miller.

Rice st, near Front, 2-story br store; cost, $8,000; o, Frank Haines.

WHEELING, W. VA.—Store bldg, granite front; cost, $25,000; o, Geo E Stifel & Co; a, Jos Leina; b, not given out.

Cor 17th and Eoff sts, store and dwell, br, s and pressed br trimmings; cost, $8,000; o, Leop Schafer; a, same as above; b, Wittkuhn & Karcher Bros.

Mt Fulton nr Wheeling, 5 fr residences; cost, $5,000; o, F Schafer; a, same as above; b, not given out.

WILKES BARRE, PA.—Butler alley, br tens and stables, cost, $12,500; o, L C Paine estate; b, P R Raife.

WAVERLY, N. Y.—A $15,000 church will be erected here. Address Rev L E Wheeler, as above.

POSITIONS VACANT.

TOO LATE FOR CLASSIFICATION.

WANTED—A FITTER WHO CAN WORK both lead and iron pipe. Good wages and steady employment. Address S. & H., Box 44, this office.

MACKITE AN IMPROVEMENT ON THE PRESENT METHOD OF ROUGH PLASTERING. Manufactured in any length slabs from 1-2 to 6 inches thick. Plastering done in one-tenth the time of old way, winter or summer. No waiting for walls to dry out. No dirt as in case of plasterer's mortar. Less weight, less conductivity of cold or heat. Can be used for deafening, back-plastering, non-conducting or isolating partitions, furring, floors, roofs, etc. FIRE-PROOF, EASILY TRANSPORTABLE.

EASTERN PLASTER BOARD CO., 52 Broad Street, New York.

SOLE AGENTS FOR BROOKLYN: CONCKLIN & DAWES, JEFFERSON BUILDING.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22.
NUMBER 8.

PUBLISHED EVERY SATURDAY.
277 PEARL ST., NEW YORK.

NEW YORK, JULY 26, 1890.
LONDON, AUGUST 9, 1890.

SINGLE COPIES, TEN CENTS.
Subscription, $4.00 per year in advance, post paid. } IN AMERICA.
SINGLE COPIES SIXPENCE.
Subscription, 20s. per annum in advance, post paid. } IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.
20*s*. in GREAT BRITAIN. Other Foreign Countries $5.
Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & CO., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $5; China, Japan, Sandwich Islands, Mexico and Cuba, $5; South America, $5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

THE WESTERN UNION BUILDING FIRE.

THE recent fire in the Western Union Telegraph Company's building in New York City has attracted unusual attention, partly because it resulted in widespread inconvenience to the public and partly because so furious a conflagration occurred in a structure intended to be fire-proof. Very large and high buildings, intended chiefly for business offices and constructed with special reference to resisting fire, have multiplied in the principal cities of the country in recent years, and this case is full of interest. A portion of the daily press in various parts of the country has jumped to the conclusion that the building was not properly constructed and condemned almost everybody concerned without discrimination. To get at the real facts of the case, especially as to the structure itself, a member of the editorial staff of this journal has made an investigation as complete as the circumstances would permit, and his report is given in another column.

Some facts with regard to the fire are hard to establish, and precisely what injury was sustained by the building cannot be known until the walls and floors are taken down, but it is at least true that the catastrophe does not show the method of construction adopted a failure as against fire. The upper floors of the building had wires numbered by thousands, mostly insulated, and with paraffine and other highly inflammable substances largely used as insulating material, besides which there were a large number of wooden tables, quantities of paper, etc., in the rooms. All this burned like tinder; so fiercely, in fact, as to imperil the lives of some of the persons in the building, but the structure itself did not collapse. That, in a nutshell, is the whole case. The upper stories of the building are to be reconstructed, but, so far as appears, this course is taken rather to improve the interior arrangement than from any fear that the walls and floors are seriously injured.

ROPE TRANSMISSION OF POWER.

SYSTEMS of rope transmission of power in manufacturing establishments have been in use for many years, but it is only quite recently that they have given promise of becoming more widely recognized as convenient and efficient means of accomplishing the ends for which they were designed. The results which have been obtained with them, it is true, have not in all cases been of uniform excellence, but this has been mainly due to the fact that designers have occasionally failed to properly appreciate the requirements of good workings. Where rope driving has been tried and has failed, examination has almost invariably revealed a disregard of correct principles of construction, and has shown nothing calculated to detract from the favor with which the system is regarded, especially where continuous high speed is required.

As regards the comparative cost of rope and other systems of transmission, and the average life of a rope of the kind ordinarily used in manufacturing establishments, it is difficult to get any precise data. As compared with leather belting, however, we have seen figures making a very favorable showing for rope, the relative cost having been in the ratio of about 8 to 1. As to the life of a rope, it has been roughly estimated that, with proper usage, it should not be less than about seven years. Cases where ropes have suddenly broken are few in number, the risk in this respect being reduced by the fact that any defects in a rope, arising from wear or other causes, will show themselves long before the point of danger is reached. In mill districts, particularly, engineers have not been slow to avail themselves of these advantages, and with the cotton rope, which is there chiefly used, most satisfactory performances have been recorded. It is but natural that, under these circumstances, the field of practical usefulness of rope driving is gradually being extended. The system has already spread from general mill practice to various kinds of manufacturing establishments, and those who have adopted it have had little cause for regret.

With wire rope transmissions for out-door use, and with long spans, running up as high as about 1,000 feet, serious trouble had been found to arise from excessive vibrations of the rope. Careful management, however, has had the effect of almost entirely eliminating these disturbing influences, and instances are now not rare where such long spans are used with perfect satisfaction,—that at Sibley College, Ithaca, N. Y., affording a good example. The span there, we believe, amounts to fully 1,100 feet, and, with some modifications in the plan as originally put into practice, no difficulty has been encountered in obtaining good results.

CARE OF HEATING BOILERS.

THE question of what should be done with a boiler when out of use and laid up for some time—a house-heating boiler during the warmer months of the year, for example—so as to best protect it against corrosion and general deterioration, has been frequently asked. The answers have, in the main, concerned themselves with the matter of internal corrosion, and various more or less effective methods of guarding against this have been suggested. One very important source of trouble and expense—external corrosion—has, however, been generally overlooked. With large boilers, used for power purposes, and under the care of trained attendants, this matter has received some attention, and proper measures are generally taken to protect the boilers on the outside as well as inside. The average house-heating boiler, on the other hand, is comparatively neglected in this respect, and to it, consequently, our remarks apply more particularly.

One of the principal causes of rapid destruction of boiler plates from without, when boilers are out of use, is the presence of sulphur in its different forms, as evolved by the coal burnt on the grates. This sulphur, besides being brought into direct contact with the heating surfaces by sublimation, tending to cause red-shortness in the metal, acts also in the forms of sulphurous and sulphuric acids which are held by soot deposits in flues and other convenient lodging places in the boiler. The sulphurous acid is formed directly by the combustion of coal, and rapidly changes to sulphuric acid in the presence of iron and of the moisture absorbed by the soot. The energy and rapidity with which sulphuric acid attacks iron is well shown by the familiar rapid rusting, as it is popularly termed, of stove pipes attached to stoves which are not used during the summer. This so-called rusting is brought about in exactly the way just described, and is nothing more than sulphuric acid corrosion. Careful cleaning of the flues and other portions of the heating surface of a boiler is the only practicable means of guarding against this form of deterioration, and should be given careful attention, particularly at the end of the cold weather term, when a house-heating boiler is thrown out of use for a comparatively long period. Compared with the internal corrosion, or common rusting of a boiler, due to dampness, when empty, the external ravages of sulphuric acid are accomplished with great rapidity and should be promptly met with suitable preventive measures.

FIRE IN A FIRE-PROOF BUILDING.

THE recent disastrous fire—that barely escaped being fatal as well—in the upper part of the Western Union Telegraph Company's building in New York City has excited especial comment and attention on account of its rapidity, violence, and the destruction caused in broad daylight in a building of modern fire-proof construction prominently situated in the down-town business part of the metropolis, and where the best skill and efforts of experienced firemen, with abundant water and apparatus, were immediately available. The building is on the corner of Broadway and Dey Street, is about 80x150 feet, and eight stories high from the street to the roof, with floors in the roof as hereafter described, and a tower about 50 feet high; it was built of stone, brick and iron, and was occupied chiefly by the telegraph company.

The rolled iron floor beams, 10 to 15 inches deep, were carried by the masonry walls and intermediate cast-iron tubular columns. Brick arches were turned between the floor beams, upon whose lower flanges they rested, and the floors were of cement or tiles on concrete bedding; the partitions and the wall linings were of plaster blocks. Some of the ceilings were formed by the floor arches themselves, and others were flat plastered on iron tees or angles suspended from the floor beams.

Air chambers were left between the brick piers and the brick facing walls.

The roof was very steep and contained one nearly full story and two stories of lofts above that. The rafters were of rolled I beams in several sections, their depth diminishing to the top, where some of those at the valleys were trussed, king-post fashion. Angle-iron purlins, closely spaced, supported the slates, and the cornice, etc., was cast iron. The main stairways were cast iron, but the spiral stairway in the tower had a light wrought iron frame and wooden tread. The elevator shaft was of brick.

The wooden door and window frames were about all the combustible material included in the real construction of that part of the building which was burned, although a gallery in the operating room had a wooden floor and railings supported on light uncased iron beams. The lower flanges of the floor beams and the columns were not sheathed or fireproofed. The seventh story was only seven feet high and was used as a battery and storage room, containing 50 battery stands, which consisted, essentially, of vertical wooden walls and horizontal wooden shelves built of pine, exceedingly dry, and stained and saturated with the oil that was used in the tops of the battery cells. A set of wardrobes was at one end of the room. The ceiling of this room was covered with multitudes of insulated cables and wires connected with the switch-board, and the operators' tables above. Part of these wires were covered with gutta percha, which of course is very inflammable, but many of them were said to have been recently re-covered with an insulation considered fireproof, and which did burn off in this case.

The eighth story was used for the operating room, and contained at one side the switch-board, beneath which, through a large hole in the floor, came the wires from the battery room. The operating room was filled with wooden tables, each accommodating four operators, placed in rows as close together as possible. Under each table was a small iron well, a few inches square, through which the wires came up to the instruments.

On the ninth floor were the offices of the Associated Press, some private offices, and the restaurant. The lofts above were mainly used for storage, and contained great quantities of books and papers, in piles and in racks made of sheet iron and gas pipe. Considerable paper was of course contained in the operating rooms and offices, much of it being a fine, soft tissue paper, in loose sheets and bundles.

The fire is supposed to have been caused by crossed electric light wires, and first broke out about 7 A. M., July 18, in the battery room, which was open on both sides with full opportunity for a draught through. The flames came up through the floor of the operating room and almost immediately set fire to the dry tables all over the room, then quickly reached the lofts and tower, barely allowing the fifty people there time to escape, which they did, some through the elevator which was run from the fifth floor.

The woodwork and contents of the battery and operating rooms were wholly consumed with the most of that in the Associated Press and office rooms above. The restaurant and kitchen and some private rooms in the rear of the lofts were not much injured. The front of the lofts and the tower were thoroughly burned out as to woodwork, trimmings, etc., though not much of the solid paper and books was consumed. The fire did not go below the battery room, where it originated and apparently made its principal ravages on the inflammable contents of the building. A hasty examination by a member of the editorial staff of THE ENGINEERING AND BUILDING RECORD disclosed remarkably small injury to the building. The floors appeared practically intact where visible or where cleared of the plaster, paper and other debris that was two feet deep in places. None of the columns examined were broken nor had apparent cracks. The main walls appeared sound and the most of their hollow brick facing was good. But few cracks were noticed in the cast-iron main stairway, which is in service now.

The roof endured well, little or no damage or distortion being evident in the heavy lower sections of the rafters. Some of the upper sections were bent and warped, and one piece entirely crippled, but many pieces not bent at all. Some of the trussed rafters had their tie rods and struts broken, etc. Much of the light wrought-iron frame of the spiral stairs in the tower retained its shape and position, but the wooden steps were consumed. The sheet-iron shelves were destroyed, and the 6-inch rolled iron gallery beams in the operating room were badly bent and twisted.

The roof and cornice trimmings were of cast iron and were not greatly damaged.

The fire lasted an hour and burned until the fuel was about exhausted. Much of the damage was done by the water and it is estimated that the building, instruments, etc., could be restored to the same condition as before the fire for about $100,000. The condition of the building is considered suitable and safe for such a restoration but the Western Union Company has decided to improve the opportunity to make some desired alterations and will rebuild the upper part of the building at a cost of about $500,000.

The lower stories of the old building are still occupied. The building was finished in 1871 at a cost of about $2,000,000. George B. Post, of New York, was the architect; J. T. Smith and J. B. & J. M. Cornell, also of New York, were the principal contractors; the former for the masonry and the latter for the iron work.

PLANS FOR IMPROVING BROOKLYN BRIDGE WANTED.

A NOTICE is issued by the Brooklyn Bridge Company as follows:

> "Notice is hereby given that the Board of Experts appointed to prepare plans for the improvement of the termini of the New York and Brooklyn Bridge in the two cities will receive plans for the improvement of the termini from any person who may choose to submit them. Plans must be in writing, and must be accompanied by drawings. No compensation will be given to any person for plans or drawings submitted unless such plans or drawings, or some portion thereof, shall be adopted, and in such case the compensation for such plan and drawing will be fixed and determined by the Board of Trustees.
>
> "The decision of the Board of Trustees upon all the questions relating to compensation shall be final and not subject to question or review. The plans must be submitted to the Board of Experts, addressed to C. W. Buckholz, Secretary, at the office of the bridge trustees, on or before September 1. Due notice will be given hereafter of the time and place where oral explanations will be heard.
>
> "Any information concerning the subject matter can be obtained at any time at the office of the trustees of the bridge."

SYDNEY, Australia, is to have an hydraulic power system, modelled, in the main, after that in successful operation at London, England. The undertaking is in the hands of the Sydney and Suburban Hydraulic Power Company.

OBITUARY.

J. ROLAND SMITH, assistant in the City Engineer's office, Albany, N. Y., died July 20, at the age of 22 years.

HENRY J. DAVISON, M. Am. Soc. M. E., died suddenly at Liverpool, July 22, on the steamer "Majestic," on which he was about to sail for America. He was born in New York City in 1835, where he had always lived. He was prominent as a mechanical engineer and manufacturer, and was connected with many business enterprises. He became superintendent of the Novelty Iron Works in New York City when only 20 years old, a year later went to New Orleans and built the two Bogardus baking ovens, which cost $400,000, then directed the taking down of the tower of the Crystal Palace in New York, for which the Common Council gave him a vote of thanks, and afterward built steamboats and machinery to be shipped to South America in sections. In recent years Mr. Davison gave his attention chiefly to gas-works, of which he erected a considerable number, introducing a water-gas system.

PERSONAL.

W. A. SOMERS has been elected Assistant City Engineer of St. Paul, Minn.

F. L. SIZER and J. S. Keerl have opened a general engineering office at Helena, Mont.

D. BONTICOU has been appointed Engineer of the Kansas City, Fort Scott and Memphis Railroad.

J. K. SROUFE has been appointed Engineer of Maintenance of Way of the Kentucky Union Railway.

RICHARD E. GANNON has been appointed Superintendent of the new Water-Works at Murphysborough, Ill.

JOHN BOGART, New York State Engineer, with Mrs. Bogart, sailed, July 19, on the Etruria, for a two months' vacation in Europe.

THOMAS W. GANNON, who has had charge of the Cairo, Ill., Water-Works for the past four years, has been appointed Superintendent.

RUDOLPH MEYER, civil engineer, San Antonia and Aransas Pass Railroad, has moved from San Antonio, Tex., to Monterey, Nuevo Leon, Mexico.

A. E. ALBY, C. E., has resigned his position as Assistant Engineer of the Elmira Bridge Company, to become General Manager of The Fire Proof Flooring Company, with main offices at 18 Broadway, New York City.

F. W WHITLOCK, Assistant City Engineer of Waterbury, Conn., is acting as City Engineer, by order of the Board of Sewer Commissioners, pending the filling of the vacancy caused by the death of City Engineer F. F. Weld.

HENRY H. KENDALL and Edward F. Stevens, architects, have opened an office at 8 Oliver Street, Boston, Mass. Mr. Kendall was recently at 40 State Street, and Mr. Stevens was clerk of the works at the new public library.

ENGINEERING SOCIETIES.

The Engineers' Club of Cincinnati held a meeting July 17, and W. B. Ruggles read a paper on the history and construction of the Ohio and Mississippi Railway.

Dr. P. H. Dudley, the inventor of the dynagraph car, gave a description of his apparatus and the diagrams taken by it, which illustrate the condition of the surface of the rails, gauge, alignment, elevation of outer rail on curves, etc., of railroad tracks.

GRANITE PAVING BLOCK INSPECTION IN NEW YORK.

As there has been complaint that the granite blocks with which a large number of streets in New York City are being paved in many cases exceeded the size permitted by the specifications, a member of the editorial staff of The Engineering and Building Record, on Monday of this week, investigated the matter. He visited seven streets where work is in progress or has just been completed, and in each measured ten blocks taken at random from different points in each street, intending to get an average of the whole. The specifications provide that the blocks shall be not less than 3½ nor more than 4½ inches wide, nor less than 8 nor more than 12 inches long. There were no blocks found among the 70 measured below the limit in either direction, but over 10 per cent. were above the limit as to width, and nearly one-half as to length. In three cases, as appears below, where the laying of the pavement had not begun, blocks piled on the sidewalk were measured, but in all other cases stones laid in the street were taken. The measurements in detail, the dimensions given being inches, were as follows:

Fifteenth Street, Between Tenth Avenue and Hudson River; Blocks Piled on the Sidewalk.

1.—13½ × 4½	2.—11½ × 5
3.—12 × 4	4.—13 × 4
5.—11 × 4¾	6.—13 × 4½
7.—11½ × 4¼	8.—11 × 4
9.—13½ × 4	10.—12¾ × 3¾

Twentieth Street, Between Tenth Avenue and Hudson River; Blocks Piled on the Sidewalk.

1.—13 × 4½	2.—15 × 4½
3.—10½ × 4½	4.—11½ × 4¼
5.—12½ × 4	6.—12 × 4½
7.—12¼ × 3	8.—11 × 3¾
9.—12½ × 4	10.—14½ × 3¼

Fifty-third Street, Between Tenth and Eleventh Avenues; Pavement Laid, and the Street Given Over to Traffic.

1.—12 × 4	2.—11 × 4
3.—12 × 5½	4.—12 × 4
5.—12 × 3½	6.—10½ × 4¼
7.—12½ × 4½	8.—12 × 4
9.—11 × 4	10.—12 × 4

Sixty-fifth Street, Between Tenth Avenue and the Boulevard; Pavement Laid and the Street Given Over to Traffic.

1.—14½ × 4	2.—13½ × 3½
3.—13 × 4½	4.—13½ × 4¾
5.—13 × 5	6.—12 × 5
7.—13½ × 4	8.—11 × 4½
9.—12½ × 4¾	10.—12½ × 4½

Sixty-sixth Street, Between Eighth and Ninth Avenues; Pavement Laid and the Street Given Over to Traffic.

1.—15¾ × 4½	2.—10 × 4½
3.—12½ × 4	4.—10½ × 4¼
5.—13 × 4½	6.—10½ × 4½
7.—12 × 4½	8.—12½ × 4½
9.—13½ × 4½	10.—11½ × 4

Lexington Avenue, Between Sixty-ninth and Eighty-third Streets; Blocks Piled on the Sidewalk.

1.—11½ × 4	2.—12 × 4
3.—13 × 3¾	4.—12 × 4½
5.—12 × 3½	6.—12 × 4
7.—12½ × 4½	8.—14½ × 4
9.—14½ × 4½	10.—13 × 5

Whitehall Street; Pavement Partially Laid at South Ferry.

1.—12 × 4	2.—12 × 4
3.—13 × 4½	4.—12½ × 5
5.—15 × 4	6.—14¾ × 4¼
7.—15¼ × 4¼	8.—13 × 4½
9.—11½ × 4½	10.—13½ × 4

These figures speak for themselves and call for no comment on what ought to be a conscientious and competent inspection service.

ANNUAL REPORTS.

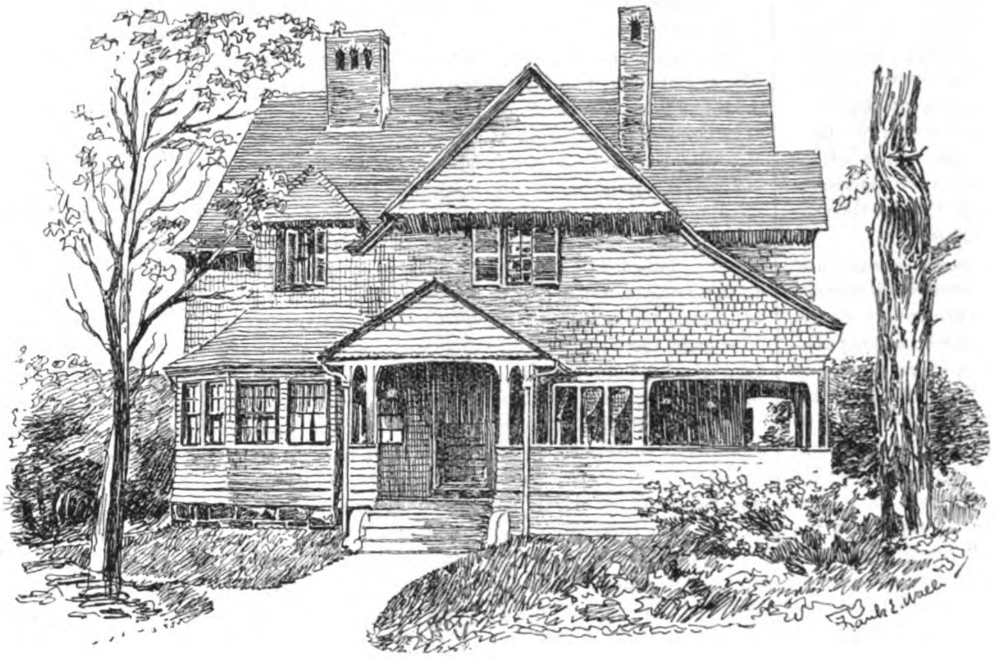
Annual Report of the Trustees of Water-Works of the City of Zanesville, O., for the year ending March 31, 1890, together with the reports of the Secretary and the Superintendent; also By-Laws and Rules, and Schedule of Water Rates.

The trustees' report shows the total receipts for the year to have been $37,345.04, and the total disbursements $35,724.09. In the disbursements is included the sum of $10,422.62 for extensions. In the report of the Superintendent, R. M. Saup, a brief review is given of the power houses and reservoirs, pumping record, fire protection and allied subjects, and a larger and higher standpipe, to be located on the most elevated site procurable, is recommended. The extensions, noted above, included 450 feet of ten, 1,904 feet of eight, 4,266 feet of six, 7,946 feet of four, and 733 feet of two inch mains. Eleven new fire hydrants were added to the works, and five new fire hydrants put in place of old Troy plugs taken out. There are now 46 miles and 4,865 feet of city mains in use.

A detailed statement of the cost of the extensions is given. A further detailed exhibit of expenditures from April 1, 1889, to April 1, 1890, is embraced in the secretary's report.

NEW ENGLAND WATER-WORKS ASSOCIATION EXCURSION.

A joint excursion of the New England Water-Works Association and the Boston Society of Civil Engineers has been arranged, to be about the middle of September. The trip will include four days in the White Mountains, and the whole cost is put at not over $25. Details will be published hereafter.



HOUSE AT WABAN, MASS.—H. LANGFORD WARREN, ARCHITECT, BOSTON, MASS.

THE WORLD'S FAIR SITE FIXED.

The Chicago Common Council adopted an ordinance Wednesday night, which is accepted as fixing the site of the World's Fair on the "lake front," with perhaps certain parts of the exhibition in Jackson Park, about eight miles south of the city, on the Illinois Central Railroad. The "lake front" location is opposite the heart of the city and very near it, where the reported plan is to add to the existing strip of land by filling in to the Government breakwater, making perhaps 250 or 300 acres in all.

Some particulars on the valuation of coal-tar pitch are given in a German paper by F. Muck. He considers the test of placing a sample between the teeth a good one as to consistency. To test the softening point a cylindrical piece of the pitch of 4 mm. diameter and 100 mm. long is bent round the bulb of a thermometer, so that there is a length of 20 mm. on the one side of the bulb and of 80 mm. on the other. The longer limb is fixed parallel with the stem of the thermometer, and the whole placed in a beaker filled with water, and provided with an agitator. The water is then gently heated till the longer limb of the little rod of pitch bends round; this is taken as the "softening temperature" of the sample.

TRANSPORTATION OF CRUDE PETROLEUM IN THE UNITED STATES.

AS BEARING on an inquiry recently received regarding the pipe-line method of oil transportation in the United States, the following extract from a paper entitled "The Different Methods of Transporting Crude Petroleum in the United States," read before the British Association for the Advancement of Science, by John H. Harris, of New York, will prove interesting. The details of pipe-line operation, given in this paper, are as comprehensive as they can be made.

Mr. Harris said that the only method of getting oil to market in the early days was by putting it into oaken barrels at the wells, each barrel of a capacity of 40 to 45 gallons. One or more of these barrels only could be drawn by teams (on account of the nature of the roads) from the wells in the wilderness to Oil Creek, where they were emptied into bulk barges, holding about 2,000 barrels. As Oil Creek was not navigable, these barges were floated down the creek on what were termed "Pond Freshets." At different points in Oil Creek dams were erected, which set back the water, and ponds were formed. When a sufficiency of water had accumulated, a wing in the dam was opened, and these barges were floated on the flood to the next dam, and the operation repeated until they reached the mouth of Oil Creek at its junction with the Allegheny River, from which point there was good flat-boat navigation to Pittsburg, the head waters of steamboat navigation in the Ohio and Mississippi valleys. This method of transportation was accompanied by great expense, incident to the loss of many of the boats, with their contents, in these drives, as well as the great labor and cost attending the building of the dams. The boats sold for what they would bring, on their arrival at Pittsburg. So late as 1862, the cost of sending one barrel of oil to New York was about $7.50, and the cost of transporting one barrel from Oil City, at the mouth of Oil Creek, to Pittsburg, about $2.30; the cost of transportation being so high as to break the market, oil at the time being sold at the wells at 50 cents per barrel.

In the latter part of 1862, a branch of the Atlantic and Great Western Railway was projected into the oil regions. Later, a line of railway was built up Oil Creek to Corry, a station on the Atlantic and Great Western, making continuous and direct railway connection to New York and the West. Still later, the Allegheny Valley Railway was opened up from Oil City, at the mouth of Oil Creek, to Pittsburg, Pa., thus perfecting the railway system from the regions to the large cities. A number of narrow-gauge railways were also built as feeders to the main lines. The lowest cost of moving oil by rail from the regions to the seaboard on the completion of these railways was about $1.04. Cylindrical tanks, 26 feet by 66 inches, made of light boiler plate, and mounted on eight-wheeled platform cars, and holding about 2,000 gallons, were used for its transportation. Bulk was broken several times, and the losses from leakage and evaporation were serious. In March, 1862, a bill was introduced in the Pennsylvania State Legislature at Harrisburg, for a franchise to carry oil in pipes from Oil Creek to Kittanning, Pa., with the privilege of extending the line to Philadelphia. Nothing, however, came of this bill. Later on, in 1864, a scheme was outlined for laying a pipe line down the Allegheny River to Pittsburg, for the transportation of oil. A large proportion of the people in the oil country, teamsters, oil producers, and railway corporations, opposed this as a blow to their prosperity, and, like the former scheme, it came to nothing.

In 1865, the first pipe line was built from Pithole, Pa., toward Oil Creek, and oil was pumped through it, the distance being 3,200 feet. Three pumps were used, and 81 barrels of oil per day forced through from Pithole to Miller Farm, a station on Oil Creek. This pipe was maliciously cut from time to time by teamsters, whose monopoly promised to be destroyed by this new method of transportation, and it was kept from utter destruction by constant patrol of armed guards.

Later on in the same year a pipe line was laid from Pithole Creek to the Island Well, a distance of seven miles. In November, 1865, still another pipe line was laid from Pithole to Titusville, which latter point was then the center of the oil-producing districts, and also a great refining point. The cost of transportation so late as December 1, 1865, from Pithole to New York, was $5.75 per barrel.

Gradually the collection of oil was made by means of pipe lines running from the different wells to central stations, and thence to loading racks at the railway stations. Much opposition was encountered from teamsters, but finally overcome, and in 1876 there were no less than eight or nine different pipe-line companies in the oil regions, whose lines radiated from the loading racks and storage tanks at the railway stations to the different wells in the interior. The business of these companies was collecting, storing and insuring oil at a stated price. They also issued storage certificates which were negotiable and used in commercial transactions as collateral. In 1875 a 4-inch pipe line was laid from the lower oil country to Pittsburg, Pa., a distance of about 60 miles. This, the pioneer trunk line, as in the case of the early local lines, at first had to be guarded by armed men to protect it from disturbance from those whose interests it antagonized.

In the latter part of 1875, the great oil field of McKean County, Pa., known as the Bradford Oil Field, was opened up, and its production has steadily increased, until at the present time probably three-fourths of the oil production of America is in and near the Bradford field.

The total pipe deliveries from 1876 to 1884, were :

In 1876	9,068,376	barrels
1877	13,012,713	"
1878	15,011,425	"
1879	20,085,716	"
1880	24.788,950	"
1881	29,674.458	"
1882	31.789.190	"
1883	24.385,666	"

Up to 1876 the refining of petroleum was carried on very largely in the oil country adjacent to the wells, and along the line of Oil Creek.

Meanwhile large refineries had been built at Cleveland, O., at Pittsburg, Pa., at Buffalo, N. Y., and on the seaboard at Boston, New York, Philadelphia and Baltimore. The increase in the price of the products of petroleum, naphtha, paraffine and the residuum, for which there was no market obtainable in the oil regions, led to the greater development of refining at the lake ports and on the seaboard, where these products could be disposed of at a profit. This led to greater shipments of crude petroleum to these points, and as the business developed, the matter of transportation assumed such formidable proportions as to engage the attention of the refiners, who, under the lead of the Standard Oil Company, of Cleveland, O., associated with the principal local pipe-lines, known as the United Pipe Company, and the American Transfer Company, surveyed and laid down pipe-lines from the regions to Cleveland, Buffalo, New York, Philadelphia and Baltimore. They also purchased the pipe line, already in operation, to Pittsburg, Pennsylvania.

The pipe-lines of America, with but a single exception, are all amalgamated in one company, known as the National Transit Company. The length of the New York line is about 300 miles. There are two lap-welded wrought-iron tubes, 6 inches in diameter the entire distance, while a portion of the way a third 6-inch pipe is laid. The number of pumping stations is 11, they are about 28 miles apart, and are equipped with duplicate compound condensing pressure pumping engines, and the greatest elevation between stations above tide-water is 2,490 feet. The Philadelphia line is 280 miles in length; diameter of pipe, 6 inches; number of stations, six. The Baltimore line covers 70 miles of direct pumping through a 5-inch pipe. The Cleveland line is 100 miles long; diameter of pipe, 5 inches, with four pump stations. The Buffalo line, 70 miles long; diameter of pipe, 4 inches, and has two stations. The length of the Pittsburg line is 60 miles; diameter of pipe, 4 inches, with two pump stations. The entire length of these lines, including the duplicate pipes, is upwards of 1,300 miles, while the length of the collecting lines of 2-inch diameter in the oil region is estimated to be from 8,000 to 10,000 miles.

In projecting these lines the experience of pumping oil through the short collecting lines of the oil country was of course available, but beyond that everything was simply conjecture. There were theoretical tables showing the resistance to be overcome in liquids passing through tubes for short distances, which, with a multiplier, would presumably give the friction for longer distances; yet there were no tables based on practical results, and certainly it was entirely experimental to attempt to force oil through hundreds of miles of pipes, over a very broken country, crossing two ranges of mountains, with rivers and creeks innumerable. The engineering difficulties were novel, yet were uniformly and successfully met and overcome. Forcing oil through the smaller pipes and shorter distances of the oil country had been hitherto accomplished by means of single cylinder pumps, sometimes called donkey pumps. The limit of their usefulness had been found in the extension of the various local lines, by the bursting of the pipes, the stripping of threads at pipe joints, and the frequent breaking down of the pumps, incident to the constant shock and jar upon pumps, pipes and connections, at the change of stroke, under the heavy pressure due to enormous frictional resistance, as well as exceptional head, due to elevation.

Pumps were frequently put in on these local lines (most of which were 2 inches in diameter and 15 miles in length), where the frictional resistance was equivalent to a pressure of 1,500 to 2,000 pounds per square inch.

The steam cylinders on these pumps were in some cases of a diameter of 30 inches, moving a ram of only 4 or 5 inches, and the concussion at each change of stroke under these pressures resembled the report of a rifled gun. Of course these conditions were preposterous, and in fact prohibitory, no pipes or material being found equal to the excessive and intermittent strain.

After mature consideration, a committee was appointed to wait upon the late Mr. Henry R. Worthington, of New York City, who in his lifetime was undoubtedly at the head of hydraulic engineers in America, and asked him to consider the conditions of the service, and give his opinion as to the type of pumping engine best adapted to meet these severe conditions. The result was that an engine was designed and constructed by Mr. Worthington, sent to the oil country, located near Bradford, set up, and connected to a section of pipe line of 4 inches diameter, 16 miles in length, reaching from Bradford to Carrollton, an oil station on the Erie Railway, which line had been laid for some time, but was in a constant state of rupture from the causes hereinbefore mentioned.

The result of the working of this machine was to revolutionize the entire transportation of petroleum. It exceeded even the maker's anticipations. The action of this pumping engine under these severe conditions was as quiet and as free from harshness of motion as could be desired. The movement of the column of oil through the pipe was uniform and constant, and whereas under the old system of single cylinder pump the column of oil came to a stop at the end of each stroke, with a variation of pressure on the gauge of several hundred pounds, with the Worthington type there was no stoppage, but a constant flow from the starting to the stopping of the engine, and an almost uniform pressure on the gauge.

From 1878 to 1881–82 the building of the trunk lines to the seaboard was continuous, and refining of oil in the oil regions proper either remained stationary, or, as the different refineries were destroyed by fire (a fate which overtakes them all sooner or later), refining was discontinued, while on the seaboard and lakes large and extensive refineries were erected.

The Worthington type of pumping engine is used exclusively on the pipe-lines of the National Transit Company. The engines vary in size according to the condition of service under which they are placed. On the New York and Pennsylvania lines, the most refined type of compound condensing engines are in use. On the Buffalo, Cleveland and Pittsburg lines, compound non-condensing engines are employed, while for the local lines a plain high-pressure pump is adopted. The average amount pumped per day through the New York lines is about 28,000 barrels, and the average head due to friction and elevation is about 900 pounds, sometimes rising to 1,200 and 1,500 pounds, depending, of course, on the piston speed of the pump.

At the different pumping stations are located one or more receiving tanks made of light boiler plate, dimensions 90 feet diameter by 30 feet high, and the oil is pumped from tanks at one station to tanks at the next, though there have been cases where loops have been laid around stations, and oil has been forced a distance of 110 miles with one pumping engine. Duplicate pumping engines are located in each station, so that there may be no cessation in pumping, one engine being in constant service.

The engines on the main 6-inch lines are from 600 to 800 horse-power, while those on the 4-inch and 5-inch lines are from 150 to 200 horse-power, and the local lines from 25 to 30 horse-power. The pipe is made especially for the service, is lap-welded wrought iron of selected material, tested critically before leaving the mills, and is known to the trade as oil-line pipe. The lengths of 18 feet are fitted at each end with coarse and sharp-cut taper threads nine to the inch, and with long sleeve couplings also screwed taper. The taper is usually ¼ inch to the foot for 4-inch pipe.

The usual way of threading iron pipe is to cut the threads straight or parallel; as a consequence only three or four threads come in contact with the thread of the socket, or help in any way to assist in making the joint.

With a taper socket, the contact is perfect throughout the whole length of the thread on the pipe, thus making a tight joint.

The lines are usually laid 2 or 3 feet below the surface of the ground, and from time to time bends are made in the pipe to allow for expansion and contraction, thus dispensing with expansion joints.

Numberless creeks and rivers are crossed by the different lines, some on trestle bridges, others by laying the pipe at the bottom of the river, with a bend up-stream. In crossing the Hudson and East Rivers at New York City, quite an engineering feat was performed, as both rivers are very deep at this point, and the tide very rapid.

The lines have become obstructed from time to time by the precipitation of paraffine, which, adhering to the pipe, reduced its area, and consequently the delivery of oil materially. A novel device is used for removing the paraffine or other obstruction. It is known to the employees as a "Go Devil," as it travels through the pipe at the same speed as the oil, being propelled by the pressure transmitted from the pumps, and as its position can only be located by its noise in motion, it has to be followed by relays of men, for should it stop unnoticed, the pipe would have to be cut to locate it.

The reduction in cost of transportation of oil by pipe is not known absolutely, as the system is in the hands of a close corporation, whose financial statements are not public property, but, having the particulars as to engines employed, miles of pipe, and conditions of service, it is easy to see that a vast reduction in the cost of transportation of oil has been effected. Certainly among other benefits that arise from this change of methods of transportation, one great danger to the traveling public has been avoided —*i. e.*, the constant liability of railway trains and barges containing crude petroleum being destroyed by fire in transit, thereby endangering the lives of passengers on passing trains and boats, with consequent loss of property, as well as blocking for a time the most important trunk lines of railway.

PROPOSED BRIDGE OVER THE SHIP CANAL AT DULUTH.

THE third annual report of the Board of Public Works of Duluth, Minn., includes a plan for a combined railroad and highway bridge over the Ship Canal through Minnesota Point, submitted by Alfred P. Boller, civil engineer, of New York City, at the invitation of the Board.

The structure proposed is a single span swinging draw, 475 feet over all, affording a clear water way of 200 feet between fenders, and 20 feet 6 inches clear height above mean water. Only two drawbridges in the world, those over Staten Island Sound, and the Thames River, at New London, exceed this in length and width of waterway, the former being 500 feet and the latter about 210 feet in each case.

The drawings which accompany the report show a central tower 25 feet square and 70 feet high, supporting two arms each 225 feet long, divided into nine panels of 25 feet each, diminishing in depth from the full height of the tower at the center to 25 feet at the ends, with end posts inclined at an angle of 45 degrees. The top chords appear to be designed to resist compression for only 5 panels from the ends, the 4 inner panels being supported, cantilever-wise, from the tower.

The trusses are 24 feet to centers and between them is placed a single track railway with footways on either side. The roadways, 9 feet 6 inches in the clear, are supported by cantilevers outside of the trusses. The turn-table will have a rim bearing and run on 58 cast-steel wheels 20 inches in diameter, with 10 inch faces. The free ends of the draw will be supported on pedestal feet with vertical screw movement operated from the center of the bridge, which will be swung by steam 90 degrees in 90 seconds, 15 seconds more being required to unlock the ends and raise the rails.

The structure is proportioned to carry in addition to its own weight a moving load of two 86-ton consolidation engines, followed by a train load of 3,000 pounds per lineal foot, and a load of 500 pounds per lineal foot of the whole length of each roadway with stresses of 10,000 pounds per square inch for live load and 20,000 pounds per square inch for dead load, modified by the formulæ for columns and shear. The material is to be a soft steel of 62,000 to 68,000 pounds ultimate strength, and 36,000 pounds elastic limit.

To form the foundation of the central pier it is proposed to dredge by pumping about 6 feet below the bed of the canal, which is here about 30 feet deep, and then drive piles by the water jet and cut them off 1 foot above the dredged bottom. Coarse sand will then be filled in to the level of the pile heads, on which will be placed an open caisson of wood, whose bottom will be composed of a grillage of solid timber 6 feet thick, on which the masonry will be built of coursed ashlar with concrete backing and granite coping.

The estimated cost of substructure and masonry is $112,079 and for the superstructure $114,290, which, with 10 per cent. for contingencies, engineering, etc., amounts to a total of $249,005.

There will be 1,200 feet of iron trestle in the highway approaches, costing, at $100 per foot, $120,000, and 1,500 feet of timber trestle on each side in the railway approaches, to be eventually replaced by embankment. This at $10 per foot would cost $30,000, or a total of $400,000 for the whole work exclusive of right of way and damages.

CURIOUS UPHEAVAL OF BRIDGE FOUNDATIONS IN HOLLAND.

IN building a three-span railway skew arch bridge over the Poldewaart, in Kettrel, Holland, J. Wuckelback writes in the London *Architect*, the proceedings were commenced in the usual manner, with the intention of having separate foundations for each pier. This was by shooting in large quantities of sand, to form dams within which, when pumped dry, the foundations would have been excavated. After a length of about 70 feet of sand-dam, 10 feet deep, had been filled in without exhibiting any signs of sinking, a heavy thunderstorm occurred, during which the whole mass was suddenly engulfed to a depth of 29 feet, whilst there arose simultaneously, at a short distance dŏwn the canal, to above the water level, a mass of bog earth of an area of 4,489 square feet. This mass increased at subsequent periods of the proceedings to the area of 9,628 square feet, and there was reason to fear for the safety of the adjacent dykes and other works. Piles 70 feet in length, when driven and tied together by waling pieces, severed bodily from their position and became useless. Fascines equally failed in producing stability. The engineer, therefore, after directing the canal water into a side cut, surrounded the site of the intended foundation with mounds of sand, and the foundation pit was pumped dry. It then became necessary to remove all the bog earth from within the space for the foundation, which was accomplished by digging out spaces of a yard square and filling them in with sand as they proceeded, until, by commencing at the exterior and working inwards to the center, all the bog earth was removed and a bed of sand had been formed in its place. The piles for the ordinary foundation used in Holland were then driven through the made ground, and the structure was completed with perfect success, the sand dam and the masses of upraised bog earth outside being subsequently dredged up in the ordinary manner to restore the canal to its original bed. The sudden rising of the bog earth during a thunderstorm is of frequent occurrence in Holland, and it would appear as if the adhesion of the masses of bog earth to the bottom was so slight that the vibration communicated to the water by the thunder sufficed to destroy the equilibrium, and the bog turf, which from its slight specific gravity will float even when wet, instantly rose to the surface.

ELECTRICAL CHAIN-HAULING IN A COAL MINE.

AN account of an electrical chain-hauling system in a coal mine near Beuthen, Silesia, Germany, is given in a recent issue of the *Zeitschrift fur das Berg-Hüttenund Salinen-Wesen*.

According to the abstract given in the Excerpt Minutes of the Proceedings of the British Institution of Civil Engineers, the gallery in which chain-hauling is employed is about 500 yards long, having a double line of rails, of 25-inch gauge. The number of wagons dealt with per shift of ten hours is 800, weighing 440 tons.

In a continuation of the gallery is situated the driving drum, 6.55 feet in diameter, mounted on a vertical axis, around which the chain is wound one and a half times. The chain having been conducted over a system of tightening pulleys, it is guided into the center of each line of rails, one for the full and one for the empty wagons. At the opposite end of the gallery it passes around a vertical pulley 4.8 feet in diameter, equal to the distance from center to center of the rails. The bearings of this pulley rest in a channel iron so as to admit of tightening. The links of the chain are 0.80 inch in diameter, and it weighs 15 pounds to the yard. It rests on the top of the wagons, and is kept in that position by two vertical projecting pieces. The wagons are placed at intervals of 20 yards on the chain.

The current is supplied from the surface Schuckert dynamo, driven by a 60 horse-power twin-engine. Running at 680 revolutions per minute, this machine gives a current equal to 35.9 horse-power. The current is conducted down the shaft to the motor by a copper cable 320 yards in length, consisting of 19 stands of wire each 0.064 inch in diameter, giving a total metallic section of 0.059 square inch. The cable is insulated with gutta-percha and inclosed in a lead pipe. The motor in the mine is also a Schuckert machine, developing a maximum horse-power of 28.8 when running at 700 revolutions per minute. Between the motor and the chain drum intervenes a system of geared wheels, which reduces the speed down to 10.5 revolutions per minute, giving the chain a velocity of 3.5 feet per second. The dynamo and the motor are both provided with ampere meters having a range of 80 amperes and resistance coils, by means of which starting is effected gradually, and the current afterwards maintained at the working rate.

THE WATER SUPPLY OF VIENNA.[*]

THE authorities of Vienna, who have to face a deficiency in the drinking water supply every winter, have determined to reinforce the existing supply, which falls short of the minimum daily volume needed of 5,100 cubic meters[†] by 1,130 cubic meters; the joint capacity of the Hochquellen and the Pottschach Springs being only 3,970 cubic meters per diem. The author gives an account of the attempts made in the past to obtain pure supplies of spring water in the Vienna Neustadt district, and describes the new project to secure deep spring water from the Neustädter Steinfeld. This district, which is a portion of the Vienna inner-alpine tertiary basin, extends for about 57 kilometers in length by 11 kilometers in average breadth. The soil is a diluvial limestone breccia, which rests upon a very deep lying impervious stratum. Into this breccia soaks the rainfall of an area of 1,413.9 square kilometers, and finds for the most part a subterranean discharge, as only a small portion is accounted for in the waters of the Pitten, Schwarza and Leitha and the Hochquelle Springs. Generals Sonnklar and Streffleur, as far back as 1859, drew attention to this district, and in 1864 a prize of 100 ducats was adjudged to Mr. Karlitschek for a scheme prepared in 1861 dealing with this source of supply. The quality of the water, which has been many times investigated, is very good, varying as it does in hardness from 13 degrees to 15 degrees, and having an average temperature of 9° to 11° Cent. The water company has acquired an area of 230 hectares. The subsoil water, which flows at a mean velocity of 3 millimeters per second, attains a maximum daily volume of 3 millions of cubic meters, the minimum volume being 0.56 million cubic meters. Of this only 1.2 cubic meter per second, or 103,680 cubic meters per diem, is to be diverted. The water is to be collected in a concrete gallery or adit 7,050 meters in length (7,710 yards), ending about 2 kilometers to the southward of Wiener Neustadt. The adit is formed at a depth of from 15 to 28 meters below the surface, and 4 meters beneath the lowest subsoil water level. The internal dimensions of the adit are 4.5 meters high, 3 meters wide, fall 0.157 meter per thousand meters. For the purpose of inspection and maintenance there will be 17 manholes. At the end of the gallery there is to be a collecting reservoir formed of concrete in two compartments. The discharge of the water from the gallery into this reservoir is regulated by sluices, and the water in it will be kept at a nearly uniform level. From the first compartment of the reservoir the water flows into the second at an adjusted rate of 1.2 cubic meter per second. The sill of this reservoir is 262.5 meters above datum. By reference to a plan, the course of the main and the position of the various subsidiary reservoirs is explained. The latter, 18 in number, vary in capacity from 49,500 to 50,000 cubic meters. The pipe system extends to a total length of about 520 kilometers varying in diameter from 1,000 to 80 millimeters. The price for water supplied by gravitation is to be 1 kreutzer per hectoliter (9*d.* per 1,000 gallons), or for high-pressure service water 1 2 kreutzer per hectoliter (11*d.* per 1,000 gallons). The works have been put in hand, and will, it is expected, be in operation in 1892.

THE HULL SEWAGE WORKS AND PUMPING ENGINES.

THE Sewage Works of Hull, England, including the pumping station and pumping engines, are described in the London *Engineer*, from information received from A. E. White, Assoc. M. Inst. C. E., the Borough Engineer of Hull, as follows:

The estimated population is 208,000; rateable value, £700,000; and land area, since the extension of the boundary in 1883, 7,901 acres. Previous to the extension the population was 154,000; rateable value, £587,000; and area, 3,621 acres. The entire borough is very flat and low-lying, and the average level of the streets, which are almost without exception somewhat above the natural surface level, is only about 9 feet above Ordnance Datum, and, as a rule, the ground nearer the Humber is higher than that farther inland. The subsoil consists of a stiff yellow clay to an average depth of about 6 feet, below which are strata of silt varying more or less in character; also in most places a thin stratum of peat, and often a quantity of running sand. Boulder clay is met with at depths varying from 14 feet to 35 feet or more in different parts of the borough. The upper clay forms a good foundation for ordinary buildings, but for structures of a heavier character it is usually necessary to go to the boulder clay. The borough is divided by the river Hull, and a line of docks, into three districts—(1) The Old Town, which was the portion formerly fortified, bounded on the south by the Humber, on the east by the river Hull, and on the north and west by docks, which portion contains a population of about 12,000; (2) the west district, west of the river Hull, and of the line of docks referred to, containing a population of about 152,000; (3) the east district, east of the river Hull, containing a population of about 44,000. The borough is further severed by five large open agricultural drains, flowing to the river Hull or the Humber, from extensive low lying districts, north of the town.

From these facts it will be gathered that considerable difficulties have had to be contended with in the sewerage of Hull. The average level of the streets, as stated, is about 9 feet above Ordnance Datum, while in the Humber, to which the sewage flows, the level of high water of ordinary spring tides is 12.37 feet above Ordnance Datum, and the level of low water of ordinary spring tides 10.10 feet below Ordnance Datum; and under such conditions the inclinations of the main sewers are necessarily very flat, and the outfalls, where pumping is not adopted, are, of course, closed for a considerable period each tide. As a rule the sewers are at least of sufficient size to enable men to enter for the purpose of brushing them out, where the inclination and flow of sewage are insufficient to render them self cleansing; and their large size assists in a rapid discharge during the short periods that the outfalls are not tide-locked; and also enables the sewers, when the outfalls are closed, to act as a reservoir, if pumping is not available, or if the quantity of water during excessively heavy rains is more than the pumps for the time being can deal with.

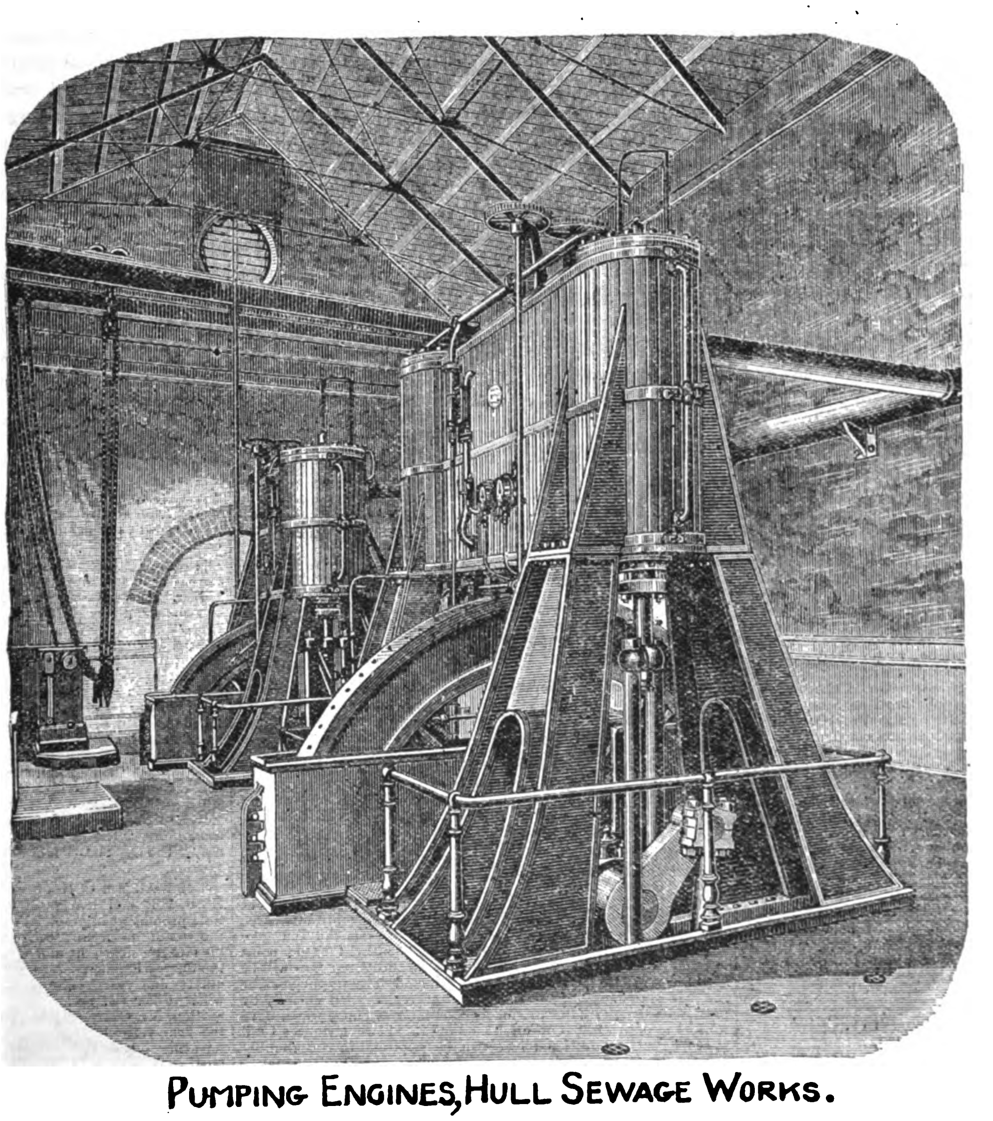
A main sewerage system for the east district was carried out in 1854 and subsequent years, and for the west district in 1863 and subsequent years. Considerable additions have since been made from time to time to such systems. During the past ten years the Corporation have expended the sum of £40,000 upon new sewers which have been constructed under various contracts, exclusive of sewers included in the works specially mentioned herein, and of works of minor importance executed by the Corporation workmen: and the Corporation are now applying to the Local Government Board for sanction to borrow a sum of £7,950 for the construction of further works of sewerage. The whole of the west district within the old borough boundary is drained to one outfall, excepting a small area which, although connected to the main sewerage system, has also a separate outfall. The main outfall sewer, which discharges into the Humber between the William Wright Dock and St. Andrew's Dock, is 6 feet 6 inches diameter for a distance of 1,900 yards, and although laid to an inclination of only 1 in 3,000, it keeps itself clear of any deposit of sewage matter. The area added to the borough on the west side in 1883, which included the Local Board district of Newington and a part of the Local Board district of Cottingham, is drained to an outfall 4 feet in diameter, discharging into the Humber within 33 yards of the main west district outfall; and since the borough extension a pumping station, hereinafter described, has been established to deal with the sewage of the main west district sewer and the Newington and Cottingham sewer, including the sewage of the portion of the Cottingham district not added to the borough.

The present sewerage system of the east district, with the exception of a short length of sewer, all falls to one point and discharges into the Humber by an outfall 4 feet in diameter; a new system of sewers, however, which is usually described as the East District and Stoneferry Drainage, is now in course of construction, and will, when completed and connected to the existing system, not only drain portions of the borough which cannot be drained by gravitation to the present sewers, but will also provide an improved outfall for the entire district. The new outfall will be to the east of the Alexandria Dock of the Hull and Barnsley Railway Company, in the face of a river embankment constructed by the company a few years since; and its level will be 10 feet below Ordnance Datum, or practically the same level as the three existing outfalls already mentioned. The outfall sewer is 6 feet 6 inches diameter, with an inclination of 1 in 3,000 for a distance of 700 yards from the Humber, and almost the whole of such length—being through made ground, or through what was until recently the foreshore of the Humber—is intended to be constructed of cast-iron pipes, supported upon piles. The pipes are flanged and jointed. A strip is cast upon the face of each flange at the outer edge, so that a space of ⅜-inch is left between each pair of flanges, when bolted together, and such space is calked from the inside with iron cement. In laying the iron pipes considerable difficulties have been encountered in consequence of the nature of the ground and of the water finding its way into the trench each tide; about half the intended length of pipe has, however, now been successfully laid. The remainder of the sewers, excepting two syphons under agricultural drains, are all of brickwork, varying in size from 6 feet diameter to 3'3"x2'2", egg-shaped, with inclinations varying from 1 in 3,000 to 1 in 450. The length of sewer from the outfall to the most distant point is four miles, and the total length, including branch sewers, six miles, of which about four miles have now been constructed. The brick sewers, 6 feet 6 inches diameter and 6 feet diameter, are in 14 inch work. Those 5 feet diameter and the egg-shaped sewers, from 5'6"x3'8", down to 3'6"x2'4", were all intended to have been in 9-inch work, but in constructing some lengths of the larger sizes through bad ground it has been found necessary to use an additional half-brick ring on the invert. The sewers of the smallest size, 3'3"x2'2", are in 4½-inch work. Cradling composed of 1-inch deal boards on elm ribs, as shown by sections of 6-foot brick sewer, has been largely used under some of the deeper sewers; and in the case of these works, as well as in previous works in the borough, such cradling has been found a cheap and efficient means of supporting the brickwork, where the nature of the ground has rendered some support necessary. One tidal gate is provided at the outfall, and a pen-stock and two further tidal gates 670 yards from the outfall, where it is intended ultimately to erect a pumping-station. Manholes with ventilating gratings are constructed at intervals of 100 yards, and provision for flushing the main sewer will be made near the highest point.

The sewage pumping station provided for the west district of the borough, for dealing with the sewage of the main west district sewer and the Newington and Cottingham sewer, is about 370 yards from the outfalls into the Humber. At low tide the sewage flows to the Humber by gravitation as before, and when pumping is necessary, the sewage is still discharged by one or both of the old outfalls. Two tidal gates and a pen-stock have been fixed on each of the old sewers, between the points of connection of the sewer leading to the station and the return sewer from the pumps; and while pumping is proceeding, the tidal gates are of course closed, and the length of sewer outside them is under pressure, varying with the rise and fall of the tide in the Humber. When the tide is low enough to allow of a discharge by gravitation, the tidal gates are open, permitting the sewage to flow direct to the Humber without passing the pumping station. There are three compound pumping engines of the vertical, inverted, direct-acting type, each capable of discharging 10,000 gallons per minute, or 14,400,000 gallons per 24 hours, when working at the maximum speed of 20 revolutions per minute. The cylinders are 18 inches and 30 inches diameter respectively, with 4 foot stroke, and the high-pressure cylinders are fitted with variable expansion gear. Each engine works two double-acting pumps, 30 inches diameter and 4 foot stroke, one pump being placed beneath each cylinder. The maximum lift is 20 feet; but as the pumps have only to work against whatever head of water there may be in the Humber, the lift varies with the state of the tide. A surface condenser is fixed on the delivery pipe from each pair of pumps, so that the whole of the sewage pumped is passed through the condenser. The boilers are of the Cornish type, four in number, each 26 feet long and 6 feet diameter, with 3 feet flue. Steam is supplied at a pressure of 80 pounds, and each boiler is capable of working one engine. A Green's economizer, for heating the feed-water, is fixed on the line of the flue, between the boilers and the chimney.

The foundations of the pump chamber are carried into the boulder clay to a depth of 32 feet below the ground level, and formed of cement concrete 6 to 1. The walls of the chamber are of brickwork in cement up to the level of the engine-house floor, and are supported against the lateral pressure of the earth by a heavy frame-work of cast-iron girders and struts, fixed at a level about midway between the base of the wall and the surface of the ground. The buildings are faced with white stock bricks, with Pateley Bridge stone dressings. A tell-tale, designed by Mr. White, and manufactured by Messrs. W. H. Bailey & Co., Salford, is placed in the engine-house. This tell-tale is worked by gearing and spindles from the engines, and by floats and platinum wires from the sump and delivery well, and shows at a glance the level of the sewage in the sump, which is the same as that in the adjoining sewers, the level of the sewage in the delivery well, which practically corresponds with that of the Humber, and also the head against which the pumps are working. The tell-tale further automatically records the above levels on a roll of paper driven by a clock throughout the day, and indicates the time at which each engine is started and stopped, and the number of revolutions worked. To make the instrument more perfect, it is intended to attach to it a rain gauge, which will automatically record not only the daily rainfall, but also the quantity falling within any given time.

The engines, pumps, boilers, etc., were supplied under a contract with Messrs. James Watt & Co., Birmingham,



PUMPING ENGINES, HULL SEWAGE WORKS.

who, together with a number of other firms, submitted their own designs in accordance with a general plan and specification supplied to them. The foundations, buildings and sewers were executed by Mr. A. W. Stanley, Hull. The cost of the pumping station was as follows: Engines, pumps, boilers, etc., £8,229; foundations, buildings and sewers, £8,873; other sundry works, £1,243; cost of site, £3,085; total, £21,430. The pumping station was commenced in February, 1883, and formally opened in June, 1884, and has worked very successfully since that time. The average volume of sewage pumped in dry weather is about 7,000 gallons per minute, or at the rate of 10,080,000 gallons per day, which is well within the power of one engine; on rare occasions, however, during excessive rains, the volume is considerably greater than all three engines can properly deal with. As a rule the pumps are worked for eight hours each tide, but during heavy rain the time is extended. The working staff consists of six men, three of whom are on duty each tide.

In a paper which Mr. White read before the Association of Municipal and Sanitary Engineers in June last, he gave the annual working expenses, exclusive of repairs, approximately as follows: Wages of staff, £515; coal, 650 tons best South Yorkshire, at 10s. *2d.*, £330; oil, stores, water, gas, etc., £130; total, £975.

REQUIREMENTS OF SPECIFICATIONS FOR STEEL AND IRON.*

THIS subject is one which could be discussed at great length, but would occupy too much space and time for the limits of this paper. The writer has endeavored to show a few of the points which should be included in specifications for quality of material only, and to give a few reasons for the use of such requirements.

Engineers have gradually made their specifications, especially for steel, more rigid and more comprehensive in their requirements; they call for higher grades with each new specification, and as the engineers increase their demands, the manufacturers put in the necessary machinery to comply with them. Engineers should bear in mind that the strain a piece of iron or steel will bear depends on the amount of rolling or forging which it receives. A fair quality of iron is that specified in the Bridge Builders' Standard Specifications, which make the ultimate tensile strength depend upon the area of section and the circumference of the piece, as indicated by their formula for ultimate strength in pounds per square inch—viz., $52{,}000 - \frac{7{,}000 \times \text{area}}{\text{circumference}}$ for tension members and all iron except plates over 8 inches wide and shaped iron. Plates between 8 and 24 inches are required to have an ultimate strength of 48,000 pounds, and over 24 inches wide of 46,000 pounds per square inch. All shaped iron is specified to have an ultimate strength represented by $50{,}000 - \frac{7{,}000 \times \text{area}}{\text{circumference.}}$ The results of these formulæ give quantities in conformity with the class of material manufactured by the best rolling mills of the country.

Great care must be taken in determining the elastic limit and elongation of the material—the qualities which should be regarded as determining the allowable strain on tension members: 26,000 pounds per square inch is generally taken as the lowest elastic limit allowed by the best authorities. The allowable elongation varies from 12 to 25 per cent., according to the section from which tests are taken. One of the most important points to look after for surface defects is the inspection, which is the most difficult to thoroughly accomplish.

Rolling mills usually have very little spare yard room for inspection of material, thus making it necessary to hurry the surface inspection in order to clear the yard, but with proper care the surface inspection can be done very satisfactorily.

A very important test of steel and iron is the cold bend test, which should be required for all specimen tests. In the tensile tests wrought iron should show a strictly fibrous fracture, and in general must be tough and easily welded, and should show no weld marks after being cooled.

A sufficient number of tests should be made to fairly represent the sizes of the material ordered and the number of full size tests should be sufficient to represent the eye-bars or tension rods; usually about one bar in 15 or 20 is considered a fair proportion.

Steel should have much more rigid inspection than iron, and should be rejected for much less important appearing defects. A steel eye-bar having any defects within 3 feet of either end before the heads are made, should be rejected, as the upsetting of the same will tend to increase the size of the defects, while in iron bars the piling and forging of the heads will be more likely to remove them. It is customary to require two tests from each heat or blow of steel, one being a ¾-inch round rolled from a small test ingot, which is poured as nearly as possible from the middle of the melt, and the second is cut from finished material, so as to represent as nearly as possible the different sizes of the same. These specimens are tested for elastic limit, ultimate tensile strength, elongation, reduction of area and bending cold.

The elastic limit of steel should be not less than 40,000 pounds per square inch for high grade steel, 36,000 pounds for medium steel and 30,000 pounds for soft steel.

The ultimate tensile strength of high grade steel should range between 70,000 and 80,000 pounds per square inch: of medium, between 60,000 and 70,000, and of soft, between 52,000 and 60,000 pounds per square inch.

The elongation in 8-inch length should be not less than 18 per cent. for high grade, 22 per cent. for medium and 25 per cent. for soft steel. The reduction of area at point of fracture should be not less than 35 per cent. of the original area. High-grade steel should be used for compression, bolsters, bearing plates, pins and rollers.

Medium steel should be used for tension members, floor system, laterals, bracing, portals and, unless high-grade steel is specified, should be used for all steel members except rivets.

Soft steel should be used in rivets only, and should be tested by actually making up into rivets, riveting two plates together, and upon being nicked and cut out, should show a good, tough, silky structure with no crystalline appearance. Rivet steel should not have over 0.$\frac{16}{100}$ per. cent. carbon.

Steel made by the Bessemer process should not have over 0.08 per cent. of phosphorus and open hearth steel not over $\frac{1}{10}$ of 1 per cent. The amount of phosphorus allowed should always be stated in the specifications, as this determines the price of the pig iron required to make the steel.

About 0.04 per cent. of sulphur is allowable and sometimes more. Excessive sulphur in steel or iron causes the same to be "red short;" that is, it cannot be hammered or forged at or above a red heat, but can be worked below that heat, while excess of phosphorus causes the metal to be "cold short" or incapable of being worked at or below the temperature of dull red heat.

Analysis should be required of each melt showing the amount of carbon, manganese, phosphorus and sulphur in the steel, and these analyses would better be made from drillings taken from the finished material.

The writer hopes to see the specifications of bridge engineers made of a uniform character, which can be easily complied with, and which will be based upon a thorough knowledge of the physical metallurgical and chemical qualities of the material.

PROPOSED SEWERAGE FOR QUINCY, MASS.

THE annual municipal reports of Quincy, Mass., for 1889, John P. Prichard, Commissioner of Public Works, includes reports by Percy M. Blake, C. E., of Hyde Park, Mass., on a sewerage system for the city. The plan recommended by Mr. Blake, to include the larger part of Quincy, contemplates a system of sewers to collect the sewage by gravity at a point near the town farm, where it is to be pumped to a discharge pipe, which will run to an outlet in deeper sea water, either 12,000 feet to Gull Point or 16,000 feet to Nut Island. The main trunk sewer would be 30 inches in diameter at the pumping station, and the outfall pipe 16 inches or larger, of cast iron, laid level. The cost of the disposal works, with brick pumping station, two boilers, two pumps each with a capacity of 2,000 gallons per minute, with pipe to Gull Point and protection of outfall, is put at $98,600, or, with reservoir at Gull Point to permit discharging at ebb tide only, $110,600. The cost with the outlet at Nut Island is given at $124,300 in one case and $140,300 in the other.

With regard to a part of the city called Atlantic, which is so situated that its sewage could not be collected by gravity at the town farm, Mr. Blake makes a separate report advocating separate collection by gravity and pumping to the main system. The cost of this, with pumping plant, he estimates at $72,320.

A FOOT BRIDGE IN INDIA.

A VERY light foot bridge for moderate spans has been designed by J. H. Apjohn, C. E., of the Orissa Coast Canal Company, and used to cross the "drainages" along the canalized portions of the Surpai River, India. The details of its construction are shown by the accompanying illustrations prepared from sketches in the *Indian Engineer*.

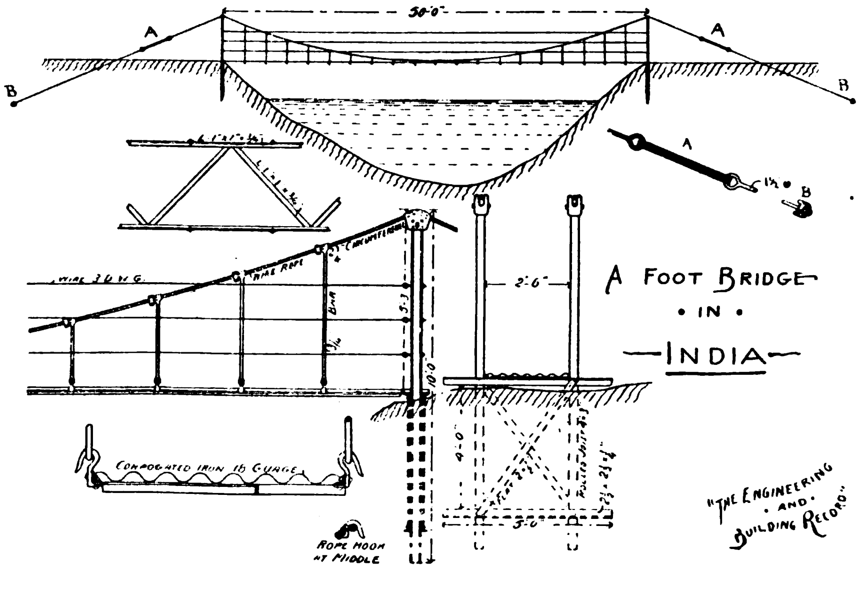
Evidently this footwalk must be very flexible, but that might be admissible for a temporary or little-used structure, and various modifications, such as the use of floor guys, a trussed hand-rail, braced towers, etc., will readily suggest themselves.

The suspension cables are adjustable at A, and are anchored at B to an old rail 20 feet long. From the appearance of the floor beam hooks it seems probable that it was intended to make portability a feature of the structure.

A PECULIAR WROUGHT-IRON CHIMNEY.

THE following particulars have recently been published of the construction of a wrought-iron factory chimney of somewhat novel character, built at Creusôt, France. The total height of the chimney is 279 feet, the diameter 23 feet at the base and 7 feet 6 inches at the top, the total weight being 80 tons, exclusive of masonry foundations. The latter are carried 3 feet 3 inches above the ground, and weigh about 300 tons. The shaft was built in successive rings, each 4 feet 1 inch high, the thickness varying from $\frac{9}{16}$ inch at the base to $\frac{1}{4}$ inch at the top. The nine lower rings were formed of eight plates each, the upper ones of four plates each. The base was encircled by a massive angle iron bolted to the foundation. The eight lower rings were lined with fire brick. The erection of the chimney occupied seventy days, including taking down the flying scaffold. The latter was of a somewhat novel character. It consisted of a central wrought-iron tube 7 inches in diameter, and provided at the bottom with four wooden crossbars or arms, so clamped that their length could be adjusted to suit the varying diameter of the chimney, and carrying the internal platform. These arms rested on angle brackets refitted to the interior of the plates. The upper part of the central tube carried four crossarms or jibs, each consisting of a pair of timbers stiffened by raking struts from the central tube. From their outer ends was slung the exterior circular platform. The latter consisted of a pair of angle iron rings, to the outer part of which was riveted a plate-iron fence, while the inner was provided with T iron stanchions. Radial bearing timbers, resting on these rings, and adjustable endwise to suit the varying diameter of the chimney, carried the platform, an annular space being left just sufficient for hoisting the plates. The latter operation was effected by a rope passing over an adjustable pulley fixed to each jib in turn, and carried down a central tube to a snatch block fixed at the bottom of the chimney. As each successive ring was riveted up, two pairs of bars were laid across, by which the scaffold was slung by four jack screws furnished with ratchet collars, and thus raised high enough to take a bearing on the next set of angle brackets.

The complete scaffold weighed about four tons, and the heaviest plate about eight hundred weight. The total cost of the chimney, without foundations, was about $8,000.



---

*A paper read by James Ritchie before the Civil Engineers' Club of Cleveland, and published in the *Journal of the Association of Engineering Societies*.

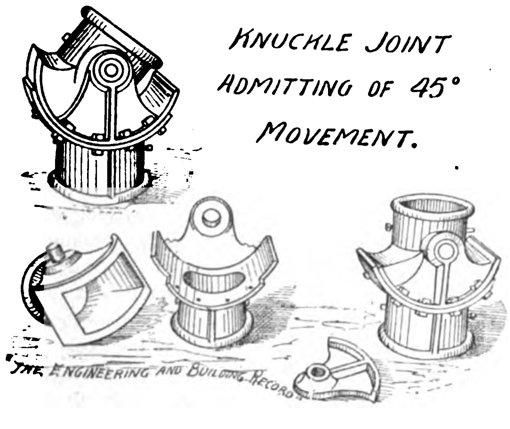
NEW ENGLAND WATER-WORKS ASSOCIATION SKETCHES.

No. XV.

(Continued from page 104.)

FORTY-FIVE DEGREE KNUCKLE JOINT FOR WATER PIPE.

THE accompanying illustration, showing a knuckle joint admitting of 45 degrees movement, formed one of the several sketches submitted at the Portland meeting of the New England Water-works Association. It was presented by F. H. Crandall, Superintendent of the Burlington, Vt., water-works. The joint is in use on the distributing pipe of the lower service reservoirs at that place. The construction is clearly shown in the cut.



THE PLANNING OF EARLY CITIES.

A DISSERTATION on "The New Town of Edinburgh, and on the Planning of Early Cities," formed the subject of Prof. G. Baldwin Brown's recent presidential address before the Edinburgh Architectural Association. Professor Brown, in the course of his remarks, pointed out the fact that the rectangular planning was a prominent feature in ancient Greece, whither it seems to have been imported from the seats of older civilization in the East. Wherever cities have to be laid out afresh on level ground, where no natural features are present to suggest a varied direction, the straight line and the right angle present themselves naturally, and would be delighted in by a people mathematically inclined. This was accordingly the scheme adopted by the old Egyptians and the Babylonians, who built upon flat alluvial plains, and who had, besides, a special reason for favoring a square or rectangular plan. This was Orientation. Among both these peoples, East and West, North and South had religious significance, and buildings or groups of buildings were commonly turned with their sides or their corners facing the points of the compass. The Egyptian tombs and the Babylonian temple mounds followed this law, which was strikingly exemplified also in the city of Khorsabad, built by Sargon II. of Assyria, near Ninevah. This city was foursquare, each side a mile in length, and provided with gates, the corners being turned towards the cardinal points. So much were the people of these regions enamored of this regularity, that in the case of Babylon itself, rebuilt by Nebuchadnezzar on each side of the Euphrates, which has naturally a winding course, the engineers first straightened the river-bed, and gave it a perfectly even line through the city, and then laid out their streets, the main ones parallel to the river quay, and the cross streets joining them at right angles.

The scheme of street planning thus established was transported to the West under the following circumstances. When the epoch of magnificence in public works came to Athens, after the defeat of the Persians, the Peiræus, the sea-front of the city, which was to Athens as Leith to Edinburgh, came to be laid out anew under the administration of Pericles, and his adviser planned it all in straight streets crossing each other at right angles. This adviser was one Hippodamus of Miletus, in Asia Minor. As native of a city on the eastern side of the Greek world, and one famous for its foreign trade and colonizing activity, Hippodamus would be familiar, through travel or report, with the old cities of Mesopotamia, and we may regard the plan be adopted at the Peiræus as derived from this more ancient source. From this time onward the scheme of Hippodamus was regularly adopted in laying out new cities throughout the Grecian world, as in the cases of Thurii in Southern Italy, Rhodes and Megalopolis in Peloponnesus. Still more remarkable was the adoption of this scheme in the magnificent cities laid out by Alexander the Great and his sucessors throughout their extended dominions. In the most splendid of these, Alexandria and Antioch, the whole length of the city was traversed in a straight line by a broad street some four miles in length, bordered by colonnades, and this was intersected at right angles by a second principal thoroughfare, the spot where the two crossed being marked by a circus or a public monument. Lines of trees in the center turned some of these streets into boulevards. Parallel to these great guiding lines ran the subsidiary streets, all measured out with the rule and set square. So far was this passion for regularity carried, that in one of these post-Alexandrine cities—Nicæa in Bithynia—the seat of the famous Council of the early Church that issued the Nicene Creed, we learn from Strabo [xii, 14, 7] that its shape was quadrangular, eleven furlongs in circuit. It had four gates, one on each side; and four main streets, running from these, met at right angles in the center, so that all four gates could be seen from a single stone set up in the exact middle point of the city.

Now it is a remarkable fact about city-planning that this rectangular arrangement could not have presented itself naturally in the case of these Greek cities, for it contradicted in nearly every case the actual lie of the ground. There were here no flat alluvial plains; but, on the contrary, marked natural features. The Peiræus was a seaport occupying a bold rocky headland stretching out into the sea, and almost cut in half midway by deep bays indenting it on each side. The highest point of the headland rose to 300 feet. There were natural features of the most prominent and picturesque character, yet this very spot was chosen for the adoption of an artificial geometrical scheme, completely ignoring the configuration of the site. In the same way with Alexandria. We are especially told that the chief public buildings of the city were grouped together so as to face the great bay which formed the principal port; but it was not the sweeping line of the coast or the boldly projecting Lochias promontory which bounded the bay that gave the guiding line to the streets, but again the geometrical right angle and straight edge. Antioch was built on a hilly site, and it cost the engineers some trouble to secure, by means of substructures, a level line for its principal thoroughfare. The constant adoption of this rectangular scheme for cities situated upon broken ground or by natural harbors naturally provokes comment, and the following may, to some extent, explain it. Hippodamus of Miletus, who set the fashion, was not so much an architect, as a sophist, or amateur philosopher and moralist. Every intelligent citizen of the more advanced Greek States was in his way a political philosopher, and had his own views of the manner in which a city should be organized, and of the proper relations of the various classes of its inhabitants. Just as naturally would he think out the ordering of the material streets and houses in which these were to dwell, and this the more readily because the professed architect in one sense of the term hardly then existed. Hippodamus, therefore, only followed the normal course. Aristotle tells us that he was a thinker who busied himself greatly about the constitution and internal ordering of States, and to lay out streets and squares was merely to him a part of the same work. While he probably obtained the first idea of rectangular planning from the older Oriental cities, he worked it in, doubtless, with his ideas for dividing the classes of citizens and regulating their moral and social life. The persistent use of the scheme in Greece is in this way a testimony to the strength of the principle of order and regularity so binding on the Hellenic intelligence, which they would emphasize in the plans of their cities as one means of inculcating the principle in its moral aspects upon the minds of the inhabitants. A similar moral idea may underlie the conception of the New Jerusalem in the Book of Revelation, which was to lie "foursquare" like Babylon and like Nicæa, and the scheme of which had as much affinity with the New Town of Edinburgh as the old historical Jerusalem had with the "Auld Reekie" of the High Street and the Closes.

There was, however, another way in which this feeling for regularity in city planning might be gratified without adopting the rectangular scheme. This was by working on the principle of radiation, and running the streets in every direction outwards from a central point like the spokes of a wheel. I am not aware that any Greek architect actually carried out such a plan for a city, but that it was contemplated as possible is proved by a passage in the *Birds* of Aristophanes, where the town built by the birds in the air is to be circular, with a market-place in the center, and roads branching in every direction like the rays of the sun.

After the Greek period had passed we find Roman practice greatly strengthening the tradition of rectangular planning. Rome itself, like Athens and all the older cities of Greece and Italy, was of the type of the Old Town of Edinburgh, and remained ill-built, with narrow, crooked streets, bordered by immensely tall houses, till after the great fire, under Nero; but the rectangular scheme was always adopted in the arrangement of the Roman camp of the late Republican and early Imperial times. This was of a square, and sometimes oblong form, with four gates, and was intersected by two or three principal streets, parallel to which ran the subsidiary alleys. As many of the new cities founded by Rome were at first merely military stations, and grew up out of permanent camps of the kind just described, rectangular planning was in this way extended over the regions conquered by the Roman arms.

It would be an interesting task to endeavor to authenticate in Western towns, which had such a beginning, the traces of this original arrangement of the camp; but, speaking generally, we may say of all the cities of the mediæval period following on the breaking up of the Roman Empire, that there was little thought of regular planning, but that they all reverted to the old fortified type, and squeezed themselves in within walls at the foot of their citadels to secure for the inhabitants the utmost possible protection in times of violence and disorder. It is very noteworthy, however, to find the regular rectangular scheme coming forward again into prominence at a more settled period of history. Edward I. of England had a delight in founding new cities both in France and Britain, and adopted the arrangement in every case of a rectangle, with a market-place in the center, and straight streets crossing each other at right angles. Winchelsea, in Sussex, is the best example of his work in the British Islands. The once busy town is now almost deserted, but the broad roads marking out the rectangular plots are still conspicuous, and where the houses which lined them have disappeared their course can be traced by the ranges of finely vaulted cellars which still exist, and give some idea of the former magnificence of the place.

If, now, it be sought to determine in the abstract what is the most effective and convenient scheme to adopt in the laying out of new quarters or new cities, the following points would have to be borne in mind. Unquestionably, where pronounced natural features exist, such as the lines of hills, or of the sea coast, these should be allowed to furnish the main outline of the scheme, and it is curious to find the Greeks, of all people in the world, ignoring the directions thus given by nature.

In the case of more purely artificial schemes, there can be little question of the superiority of the rectangular over the radiating plan. The latter may give scope for a few fine avenues, as in the case of those that converge to the Arc de Triomphe at Paris; but the subsidiary streets have no definite place or plan, while in the parts near to the center, where the ground is most valuable, the plots of land are angular and awkward in shape, and offer perplexing problems to the builder.

In cases where a city or a quarter has to be laid out afresh in a frankly artificial manner, it is probably the soundest taste not to try for picturesqueness and variety, which, after all, will never have the genuine charm of what comes by happy accident, but to aim at stateliness of effect and at an air of calculated unity embracing the whole complexus of buildings dealt with. A rectangular scheme, according to which the space laid out must be definitely bounded on each side, and the whole have compactness and clearness of outline, secures this far better than any radiating scheme, and has the further advantage of giving a natural place for open squares, which come easily and effectively into the composition.

WATER in the city reservoirs at Rochester, N. Y., recently fell so fast as to cause apprehension, and attempts were made to diminish the consumption by stopping the use of garden hose, etc., and by diminishing the pressure. A saving of about 1,000,000 gallons a day seems to have been made by these means.

Novelties.

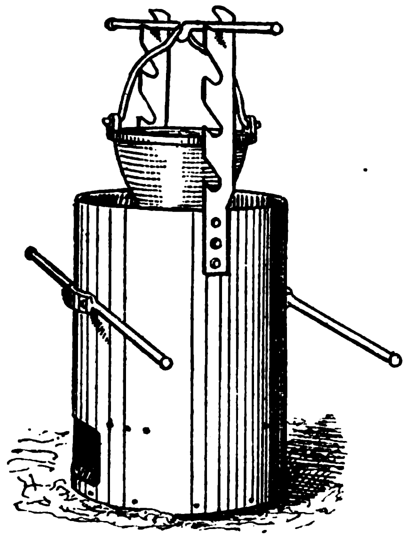
Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course, be understood that the selection does not imply indorsement.

FURNACE FOR USE IN LAYING WATER MAINS.

SEVERAL months ago this journal had an inquiry from a subscriber asking where he could obtain a furnace for melting lead to use in laying water pipe. There is given herewith a cut showing one form of such a furnace which, with slight variations, may be made to do duty for almost any occasion. The long carrying handles may be replaced by hooks on the side of the furnace into which the workmen may insert bars or pieces of pipe with which to carry it. The grate is made in one piece and rests on angle irons without any fastening, so that it is easily removed. The notched supports which carry the kettle are of great convenience in regulating the temperature of the lead. No door is furnished for firing because there is ample room between the kettle and the sides of the furnace to throw fuel upon the grate. The ash door can be closed, if one wishes to shut off the draught, by a piece of sheet iron. This furnace is manufactured by the Taunton Locomotive Manufacturing Company, of Taunton, Mass., and was designed by the Treasurer, William R. Billings, who is the author of "Some Details of Water-Works Construction," published by this journal. This design grew out of Mr. Billings' practical experience in laying water mains.



Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

THE PROPOSED WATER-WORKS CRIB IN CHICAGO.

VICTORIA, B. C., July 16, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: In reference to the inquiry of a correspondent in your last issue, I can give you a few facts and some opinions.

In January, 1887, the undersigned, together with Mr. B. Williams and Mr. S. G. Artingstall, reported to the Mayor and City Council of Chicago, among other matters, the plan of increasing the water supply of the city. The new pumping station was recommended to be built in the central part of the city and a new tunnel from it to the lake. The report further said:

"We believe that a submerged intake will afford a more reliable and safer structure so far as injury from passing vessels and stoppage by ice are concerned, than a structure projecting above the water.

"With the sewage kept out of the lake there is no need of locating the intake further than two miles from the shore, where water can be obtained sufficiently free from suspended earthy matter, and where a depth of about 30 feet is generally found, which is the least depth desirable for a submerged inlet."

The main recommendations of this report were adopted, except the suggestion of a submerged intake and limiting the length of the tunnel to two miles beyond the shore. I myself have never been able to hear of any good reasons why these exceptions were made, and I am not aware that any other engineer was ever publicly consulted with reference thereto, nor do I know who is responsible for advising this remarkable engineering.

The reasons which led us to recommend the submerged intake were about as follows: In 30 feet of water, about two miles from shore, there would be no danger to a submerged structure, either from vessels during storms or from ice. If the area of the intake is made large enough to reduce the velocity of the inflowing water to but a few inches per second, no drift will tend to obstruct the grating.

In addition to the great economy of a submerged intake, the large structure reaching above the surface of the lake is a decided disadvantage in several respects. The undesirability of banishing human beings for the cold winter months to a desolate spot among fields of ice did not influence our opinion, because if necessary this hardship should and could be endured for the benefit of a large community. But we considered that the structure in the lake would prevent the free movement of ice and therefore be exposed to unknown but enormous strains. If no injury resulted therefrom directly, the ice would probably be forced both up and down the face of the crib and tend to obstruct some of the ports, which trouble has occurred at the present crib. The stone and iron at the ports, and of the structure itself, when cooled by radiation would cause the formation of slush and anchor ice about them, which, as in the case of the previous crib, tend to obstruct the ports. Regarding this question of anchor ice, Sir William Dawson, in a discussion at the Canadian Society of Civil Engineers stated: "The fact that it forms most readily in open water without any covering of ice, and in clear, cold weather, indicates that radiation from the bottom has an important influence in its formation; but where the water is sufficiently cold it may crystallize on any nucleus presented to it, and more especially, it would seem, on metallic bodies and stones which are good conductors of heat." Wooden gratings of a submerged intake will probably be free from the danger of anchor ice.

All these reasons seem to indicate that such a structure as proposed is objectionable, and I am not able to discover for it any advantages (except as a terminus for excursion boats), much less any justification for an outlay of over a quarter of a million dollars.

We have, moreover, some positive evidence to confirm these views, as a number of submerged intakes have been successfully used in different lake cities. The largest one is in front of the city of Toronto. It stands in about 26 feet of water, and is about 2,000 feet from shore. The crib is 40 feet square and covered with an oak grating consisting of 2-inch bars and 3-inch openings. It was put into use in 1882, was examined for the writer in the fall of 1888, and found to be perfectly clean. It had never required cleaning. Nor has there been any obstruction from floating ice, as this can readily float over the crib: nor from anchor ice, because of the oak grating. But even in Chicago the present intake for the old Hyde Park Water-Works is submerged, and, although comparatively near shore, it has been working for several years without interruption.

This subject is certainly of interest to engineers, and I hope you have received, or will receive, further communications, giving actual facts and representing different sides of the question. RUDOLPH HERING.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department.* Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

AIR IN WATER.

G. F. COOPER, Superintendent of the Xenia, O., Water Company, writes: "The water here during the summer time is full of small bubbles of air, which makes it look milky when first drawn, but after it has been standing a few minutes the air rises and the water is then clear. Is there any way to remedy it?

We have splendid water, but some people think because it looks milky when first drawn it isn't good?"

[Charles B. Brush, Chief Engineer and Superintendent of the Hackensack Water Company, of Hoboken, N. J., to whom the above inquiry was submitted, writes:

"I do not understand the anxiety of your correspondent in relation to the air bubbles in his water mains. He states that he has splendid water, but that when it is drawn from the mains it looks milky, but after standing for a moment the air rises and the water becomes clear. The condition which gives so much anxiety is one which I have spent a great deal of money to obtain. I have no doubt that the good condition of his water is largely due to the amount of air in it. Nothing pleases our consumers so much as to obtain their water in this condition. If he really wants to get rid of the air he can do so by putting some air cocks in the summits of his mains and blowing the air off. This may be necessary, if there is such an excess of air as to interfere with the operations of his plant. As soon as his customers understand, however, that this æration of the water indicates a high degree of purity and vitality, I believe that further complaint on their part will cease."]

HIGH RANGE PYROMETER.

RUFFORD & Co., of Stourbridge, England, write: "Do you happen to know any makers of pyrometers? We want to have one to register at least from 2,000° to 3,000° Fahr., but cannot find one.

"Our old pyrometer was marked on its face, 'A. Krauss, Paris.' We wrote to Paris to Krauss, but the letter was sent back through the dead letter office. Ours was like a gun barrel with a circular indicator at one end and registered to upwards of 2,000, but it is now worn out."

[We have been unable to find out anything about the firm, "A. Krauss, Paris." Generally speaking pyrometers registering to between 2,000 and 3,000 degrees are not called for owing to their unreliability at such high temperatures, which approach and even pass the melting points of some of the metals used in their construction. Manufacturers frequently state in their catalogues that their pyrometers will indicate correctly only up to 1,000 degrees, though the instruments are graduated up to 1,500 and 1,600 degrees. Such pyrometers can be bought from almost any large dealer in, or maker of, temperature and pressure indicators and appliances. Temperatures beyond their range can, however, easily be determined by a calorimetric method, which consists in exposing a known weight of metal, say iron, to the temperature to be determined, and then cooling it in a known weight of water, noting the initial and final temperatures of the water. The following simple calculation will, with these data, give the desired temperature:

Let T = temperature to be determined = temperature of exposed weight of metal;
" t = initial temperature of water;
" t' = final " " "
" W = weight of amount of water used;
" w = weight of metal;
" s = specific heat of metal.

Then
$$T = \frac{W(t^1 - t)}{w s} + t'$$

For temperatures above 3,000 degrees platinum may be substituted for iron. The specific heat of iron may be taken as .1138, and that for platinum as .0382.]

FILTERING SEWAGE IN BERLIN.

IN a recent paper discussing sewage disposal for London, England, Crawford Barlow, M. Inst. C. E., said of Berlin, that, with a population of 1,400,000, located on 15,266 acres of a flat, sandy plain, there is a total of 30,800,000 gallons of sewage per diem from the 12 drainage districts. This is pumped to several irrigation farms where 6,780 acres of land are in use, of which 3,719 acres are drained.

Mr. Barlow continued, "with sewage five times more charged with fæcal matter than that of Paris, the health of the cultivators and of the inhabitants of the domain is perfect. There is no typhoid fever. The city of Berlin has already established two convalescent homes in the houses of its domains: it is about to found two others in the very middle of its irrigation fields. Typhoid fever has diminished at Berlin till it represents only one-third of what exists in Paris. The towns and villages which are close to the sewage farms make no complaint, and their sanitary state is excellent. Part of the effluent from the sewage farms of Berlin is collected in an ornamental lake in which fish breed freely. This fact alone suffices to show how thoroughly all putrescible matter is removed from the sewage in a well-arranged, well-managed irrigation farm. The chemical analysis of the effluent water from the farms tell the same tale

* * * "We drank of it, for we knew beforehand that chemical analysis showed it to be destitute of organic matter, and to contain fewer microbes than spring water does.

* * * * * * *

"There are no bad odors, and no complaints are made by the convalescents. In the fields of Malchow the meadows of rye grass especially struck our attention. The fourth cutting was being made of grass as green, as thick, and as straight and high, as can be imagined. Seven cuttings are annually made of the same value."

DOMESTIC PLUMBING HEATING LIGHTING & VENTILATION ENGINEERING

PLUMBING IN A SEVENTY-FOURTH STREET HOUSE.

In a new block of five 4-story houses on West Seventy-Fourth Street, New York City, the plumbing in each comprises a servants' bath-room and slop-sink on the fourth floor, two wash-bowls and a toilet-room on both the second and third floors, a butler's pantry on the first floor, and kitchen sink, boiler and laundry tubs in the basement.

The second and third floor toilet-rooms are finished in ceramic tiles and oiled wood-work. Each contains a water-closet, wash-bowl, and a full-length porcelain bath-tub, and that on the second floor contains also a sitz bath.

The water-pipes in these rooms are brass, silver-plated; elsewhere throughout the house they are A A A lead; everywhere exposed. The basement fixtures are polished brass; above they are silver-plated.

City water is delivered by a gas-engine pump in the basement to a tank T Fig. 1, built in an alcove of a fourth story room. This tank is about 7 feet by 2 feet 6 inches by 4 feet deep, copper lined, and neatly cased in wood. The space under it is occupied by a large cupboard, A, affording access to the pipes, and an alcove B that contains a planished copper bath-tub. The tank is filled through a 1¼-inch pump pipe C, and overflows through the pipe D. E is a tell-tale to the basement. F is the emptying pipe, and G is the house service pipe, with a check valve H that opens upwards only to prevent water from rising and overflowing the tank when the city pressure is high. I is a trap vent-pipe. J and K are hot and cold water pipes, respectively, to the servants' bath-tub L, and M M are lead safes.

Figure 2 shows the hot and cold water distribution system in the kitchen. A is an 80-gallon double boiler, the inside portion of which, under tank pressure, is supplied by the pipe G, and delivers hot water to the upper floors through the pipe C with branches D and E to the second floor basins and bath-rooms, and F to the third and fourth floors. Cold water is supplied to the second story bath-rooms and basins through the branches H and I, and to the third and fourth floors through the branch J. The outside boiler is supplied with water under street pressure through the pipe B, and delivers hot water through a pipe N, with branches O and P, to the second story basins and bath-room, and a branch Q to the basement fixtures. Cold water from the street is delivered through branches K and L to the second story bath-room and basins, and through a branch M to the basement fixtures. R and S are hot-water pipes to the laundry tubs, where they are both connected to the same branch. Their check valves T T close against an upward current, and prevent the water from one boiler escaping into the other. The pipes B and C are connected by a special branch with a valve V (not shown) which is generally closed, but may be opened to admit tank water to the street boiler, or *vice versa*. U U are check valves opening upwards. This arrangement gives separate supplies under street and tank pressure, respectively, to the second floor and to the laundry. All the hot water cocks are above and all the cold below; all those at the left hand control the tank pressure system and those at the right the street pressure system, so that their operation becomes very simple, and is facilitated by a brass label on each cock. W W, etc., are marble slabs to which the lead tacks are attached before they are put on the wall. Z is the tack, and X X are common screws that enter the countersunk holes Y Y, which are then poured full of lead.

Figure 3 shows the arrangement of hot and cold water pipes in the laundry, where the cocks are in the same horizontal line, and set at the lowest parts of the pipes so as to completely drain them.

This plumbing was done by Faulkner & Blackburn, of New York.

THE WATER SUPPLY OF BUILDINGS IN A COLD CLIMATE.

J. C. Adamson, of St. Paul, Minn., read at the recent convention of the National Association of Master Plumbers, at Denver, a paper on the water supply of buildings in a cold climate, in which he said: "As a first proposition, I would say that in a properly constructed steam heated building the controlling of the water supply is little or no more difficult in a cold climate than in a warm one. The only mistake that is liable to occur in such a building is the putting of the pipes in exposed parts of the building; in a recess of an outside wall, or crossing an attic with nothing but the roof to protect from the weather. I have in my mind a very prominent building in St. Paul where the pipes froze last winter in a recess of a stone wall three feet thick, and were only kept from bursting by the diligence of the engineer in charge, by putting steam up through the rain conductors, which are in the same box. This difficulty, along with many others, will be avoided when the architect will recognize the importance of having a place provided in a building for the plumbing pipes.

"As a second proposition, I would say that in a poorly constructed, poorly heated building, it is next to impossible to keep your water supply in order in such a climate as ours. In an ordinary self-contained dwelling in a climate where the thermometer takes an occasional dip to 40 degrees below zero, with your water pipes of extra strong lead, seven feet below the surface on the outside, and two feet below the basement floor on the inside of the house, with stop and waste at same depth at foot of each riser, with a rod for convenience reaching to kitchen sink with proper drainage for said wastes, your pipes that are above ground throughout the house graded to empty when shut off, and all placed on inside walls, not under floors, if possible, exposed to view or easily accessible, and you have done all you reasonably can do for the successful working of the job.

"There is a third class of buildings which is commonly met with and uncommonly difficult to handle in the matter of water supply, that is, the unheated tenement, or block of stores with flats over, often well built, but each tenant to furnish his own heat, and probably one-third of the store, or apartments unoccupied. This is where your troubles are at an end, as the Quaker preacher told the young man when he married the shrew, but forgot to mention which end, as the young man soon discovered to his sorrow.

"Now let us see what is commonly done, what is occasionally done, and what ought to be done to get this job to run with some degree of comfort and credit to all concerned, more especially to the man who gets blamed for all the mischief arising from having executed the cheapest kind of a contract, taken under the keenest competition.

"It is not a common occurrence to see a job of the kind with a single line of pipe run up along the stack to supply every fixture from cellar to garret, and under the conditions above mentioned, that is partly occupied, and, of course, partly heated with the mercury meandering among the twenties, how is it possible under such circumstances to control the water supply? Well, very often the water is allowed to run a good stream night and day. That is, doubtless, occasionally effective, but entirely inadmissible for reasons so apparent I need not mention them here.

"Then let us consider the best method of fitting up such a building, and the first important consideration in this connection is, to run a separate riser from a point two feet underground of basement to each and every flat or store or apartment that is to be occupied as a separate tenement; next, to have each line controlled by the occupant at a convenient point in their apartment, by means of the usual rod for stop and waste, or slide with chain and cranks for three-way valves or cock placed, as before stated, below the freezing point, and, lastly, all pipes to be exposed to view, and away from outside walls. You will readily ob-

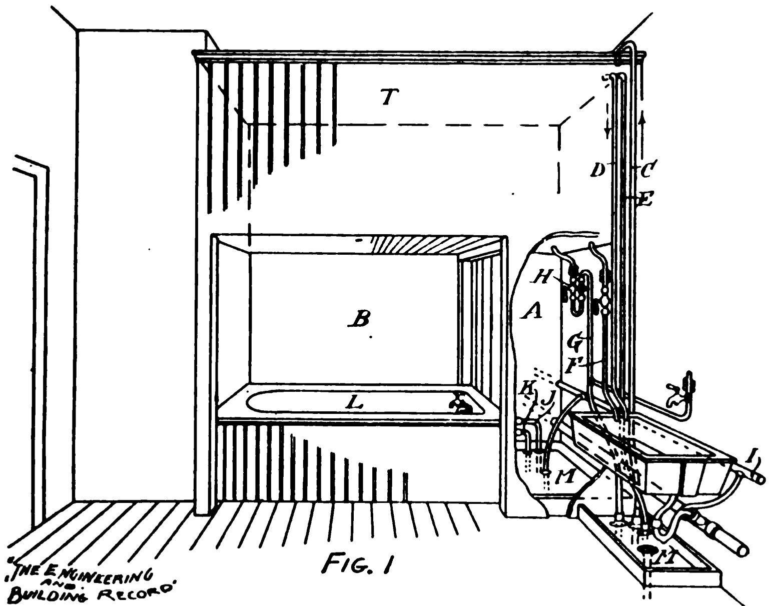


FIG. 1

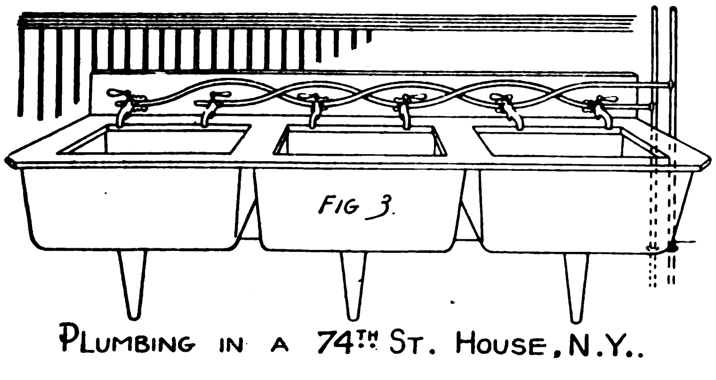

FIG. 3.

PLUMBING IN A 74TH ST. HOUSE, N.Y..

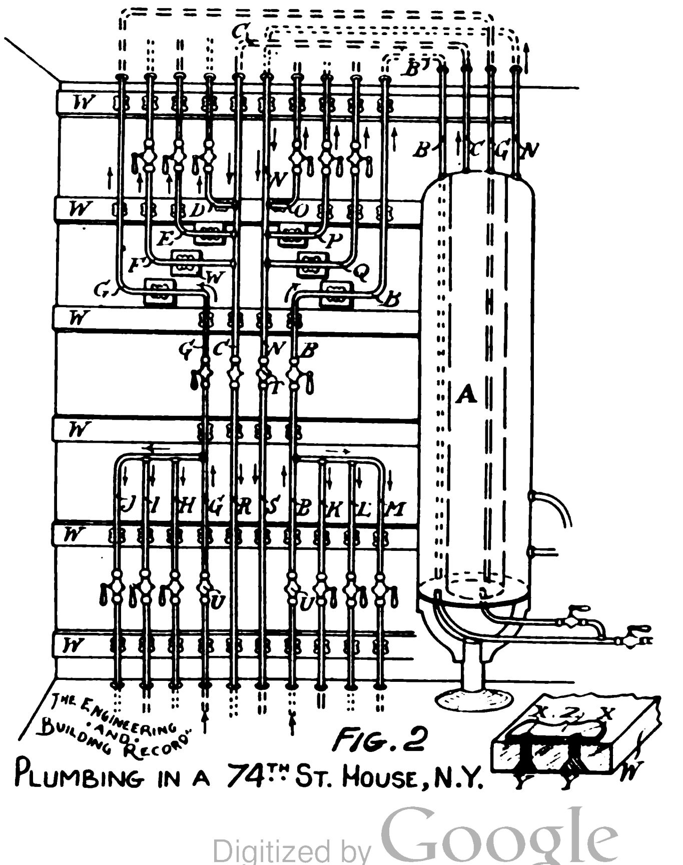

FIG. 2

PLUMBING IN A 74TH ST. HOUSE, N.Y.

serve the advantages of the separate supply, as in the case of a vacant apartment, the water is drained off completely, all fixtures emptied and the traps filled with salt, when all danger from freezing is avoided in that quarter, with the exception of the supply pipe, which may be passing up through for the floor above. This will have to be taken care of. Many details suggest themselves as to the best method of arranging the shut-offs, etc., but I draw this paper to a close by emphasizing my last proposition; that the pipes be exposed to view, and would recommend that the riser be of galvanized iron, standing out from the wall in the same manner as you would run a steam pipe. You will find on reflection much in favor of this system. For example, they can be made to look well, no breaking of walls or ceiling in case of a freeze up, and they are in position for being thawed out, or for large rough temporary boxing, or packing, if thought desirable, in an unoccupied flat."

Experiments on cable propulsion for street cars made on the Chicago City Railway some time ago showed that at an average speed of about 7 miles per hour one horsepower was required for each ton of cable and machinery, and 0.2 horse-power for each ton of car and passengers.

Novelties.

Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course, be understood that the selection does not imply indorsement.

PORTER & CO.'S HOT-WATER BOILER.

In the accompanying illustrations is shown a modified design of the Page boiler, adapted for hot water heating by W. F. Porter & Co., hot water and steam heating engineers, of Minneapolis, Minn.

It will be noticed that the general character of the boiler has not been changed. The front, however, is cast in one piece, giving a more substantial appearance. Clean-out doors are used at the sides (S), to get at the sections instead of having handholes as formerly. The check draught D lifts instead of revolving and trouble from sticking, due to corrosion, is thus avoided. Openings are left in the top section and on the body of the fire-pot in case it is required to run a separate pipe to a radiator. The grate is made in two sections; one is a round center piece, C, which rotates and can be dumped for cleaning out clinkers, while the other, R, forms an outer ring which rests upon rollers and can be revolved.

The grates are made in two styles, one permitting operation by a lever outside with connecting rods to the grates, and the other being worked by a handle over the ash-pit door. The latter is higher than in the older design, enabling easier inspection of the grate.

In the illustrations Fig. 1 represents a vertical cross section of the boiler and setting; Fig. 2, a vertical longitudinal section, and Fig. 3, a perspective. Figure 4 shows, in greater detail, the screw joint between the boiler sections.

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

LEAD OR GALVANIZED IRON PIPE.

G. S. Appleton, of Helena, Mont., writes: "I am exceedingly anxious to get an opinion from good authority upon the relative value of lead and galvanized iron to be used as hot and cold water service pipes in ordinary house plumbing, where pipes are completely covered in building.

"If anything has been written upon this subject please refer me to it; otherwise I would suggest that it might be a profitable subject to discuss briefly in the columns of your paper.

"In the case now in question pressure is from tank in the attic; boiler, 60-gallon, heated with an ordinary fire-back in a range; water, soft; the exposed portions of pipe are to be of polished brass."

[We do not know that any comprehensive and authoritative comparison of these pipes has ever been published, and their relative value in any particular case must depend largely upon special conditions not indicated by our correspondent. The fact that elaborate and expensive systems of plumbing are now sometimes put in under similar circumstances with lead and sometimes with galvanized iron throughout, however, indicates either that those doing the work are divided in opinion or regard the choice as immaterial. Illustrated descriptions of plumbing in New York houses recently published by this journal embrace examples of the use of both kinds of pipe.

The relative advantages of lead, tin, brass, iron and galvanized iron pipes, are discussed in the "Catechism of the New York Trade School," as printed in Vol. XV. of this journal, as follows:

1. What size should the pipe from the street-main to the house be?

Should be as large as possible, according to amount of pressure and size of building.

2. What material is used for this pipe in New York?

Generally lead pipe.

3. What other materials besides lead are used for supply-pipe?

Galvanized iron, black iron, tin-lined lead pipe, brass, and occasionally cast-iron pipe.

4. How is iron used?

Galvanized and black—sometimes lined with block-tin or glass.

5. What are the advantages and disadvantages of lead pipe?

Advantages—Pliability, strength, and durability.

Disadvantages—Danger of poisoning and of corrosion.

6. What are the advantages and disadvantages of plain iron pipe?

Advantages—Cheapness, ease of putting together, and safety from poisoning.

Disadvantages—Want of durability, owing to rust eating holes in it, and of filling it up.

7. What are the advantages and disadvantages of tin-lined pipe?

But little used. Difficulty of preventing water from getting between lining and pipe.

8. What are the advantages and disadvantages of glass-lined pipe?

An excellent pipe in many respects, but liable to have lining broken from bending and from frost.

9. What are the advantages and disadvantages of galvanized iron pipe?

Advantages—Cheapness and freedom from rust, durability, etc.

Disadvantages—Some waters decompose zinc, and the salts are poisonous.

10. What are the advantages and disadvantages of brass pipe?

When well tinned it is light, strong, and durable; objection is that it is supposed to be poisonous when not tinned.

11. What are the advantages and disadvantages of block-tin pipes?

Perfectly safe; but expensive and difficult to work. Hot water affects its durability seriously.

12. What are the advantages and disadvantages of tin-lined lead pipe?

It is a safe and durable pipe for cold water. Hot water produces an unequal expansion in the two metals and soon destroys it. Lime also affects the tin.

13. In using tin-lined pipe what must be guarded against?

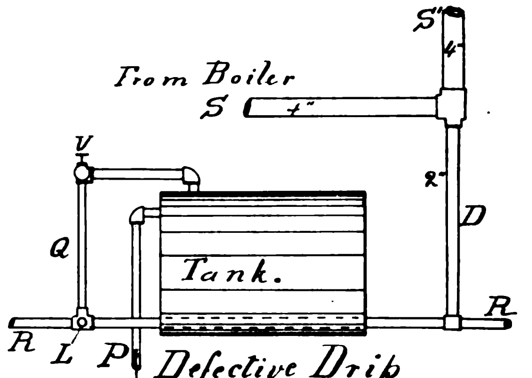
The lining should be carefully preserved in making the joints, either by using the proper kind of solder, or using tinned-brass ferrules.

As regards danger to health from using galvanized iron pipe, as we have before said (page 342, Vol. XVII), with ordinarily pure water, there need be no fear. All drinking water will dissolve zinc on galvanized pipes, but under no circumstances can there be enough dissolved to harm the human body without making the water so milky and giving it such a strong metallic taste that no one would use it. We should be glad to have further correspondence in regard to this matter.]

DEFECTIVE DRIP CONNECTIONS IN A STEAM HEATING SYSTEM.

A correspondent writes as follows: "In overhauling a steam-heating plant which could not be made to perform satisfactorily the peculiar arrangement of drip connections, shown in the annexed cut, was found.

"From the 4-inch main steam-pipe S, a riser S' extended upward to supply the radiators, and a drip-pipe D, extended downward, connecting with the return main R. From this, again, a pipe Q led upward and into a tank. Ordinarily, exhaust steam was used for heating, the pressure in the steam mains being about five pounds. Provision was made, however, for using live steam for heating when the engine was not running, the valve V in that case being closed, and the water of condensation returning to the boiler through the pipe L, with suitable trap connection.



Defective Drip Connections.

"It will be seen that, when using exhaust steam, there was thus an open circuit from the pipes S and S' through the drip-pipe D and returns R into the tank and out through the pipe P, which was designed for an overflow-pipe, into the sewer. While the vertical pipe Q helps to form a water seal, in this case about five feet deep, the water was blown out with a slight increase above about $2\frac{1}{2}$ pounds pressure. As a consequence, a large portion of the steam which ought to have been available for heating, took the more direct course into the tank and thence into the sewer. When turning steam into the system, the tank invariably heated up long before any heat could be secured in the radiators. Will not a steam trap, interposed between the steam and return mains, remedy the difficulty?"

[The interposition of a trap between a steam and return main will prevent a serious loss of steam in that particular direction or pipe, but in cases where there are many connections between the main and return, each would require a trap, and the number might make the remedy impracticable. A trap of the proper kind in the pipe Q will stop the loss of steam through the tank. Of course the pipe Q will be closed when live steam at boiler pressure is used, and the water is being returned directly to the water.

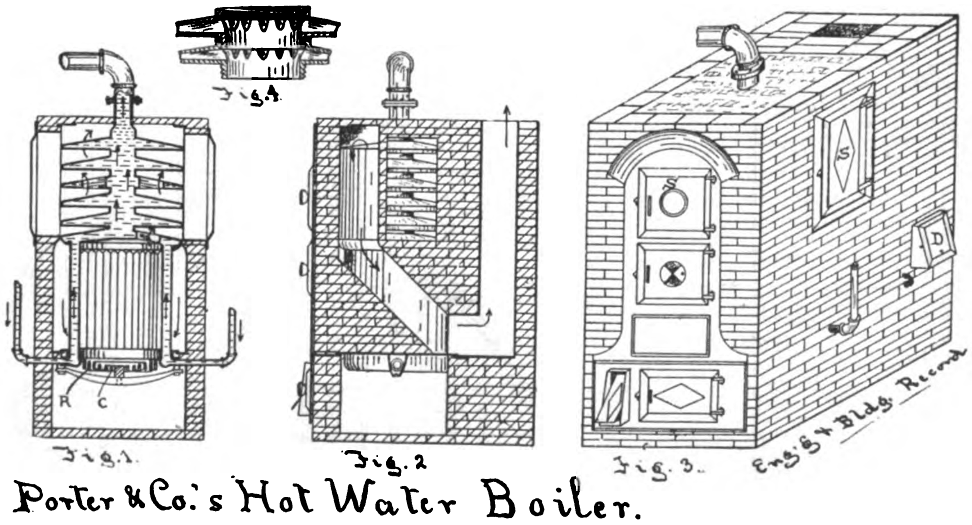
We do not see the necessity for a tank unless it is for a receiving or blow-off tank, to comply with city ordinance.]

TEXAS PLUMBERS' ASSOCIATION ORGANIZED.

Texas plumbers held a meeting at Waco, July 15, and organized a State association, with officers as follows:

F. J. Maddin, of Sherman, President.
J. A. McWhirk, of Dallas, Vice-President.
J. S. Brazleton, of Waco, Secretary.
G. W. Preuit, of Waco, Sergeant-at-Arms.
Frank Pettit, of Denison, Treasurer.
D. J. Sullivan, of Dallas; D. J. May, of Galveston, and F. A. Campbell, of Dallas, Executive Committee.

The next meeting will be held in October, at Dallas.



Porter & Co.'s Hot Water Boiler.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ARCHITECTURAL COMPETITIONS.

Cincinnati, O.—The Board of Education are asking for plans for school buildings, one to cost $70,000, and one to cost $40,000. They will pay $500 for plans accepted for first building, and $300 for second.

Louisville, Ky.—Mayor Lyons invites plans for remodeling the present City Hospital Building, and also for a new building. The sum of $70,000 must cover the cost of remodeling, and $70,000 for the first section of the new building. Plans must be sent to the Mayor by August 2.

CONTRACTING INTELLIGENCE.

For works for which proposals are requested see also the "Proposal Columns," pages i-ii-126-127.

WATER.

For Additional Water Items see Proposal Columns

Asheville, N. C.—There is some talk of establishing a storage system in connection with the local water-works supply of this place.

Roxbury Village, N. Y.—Steps will very soon be taken towards constructing the projected water-works system at this place.

Chambersburg, Pa.—The sum of $35,000 has been voted to make improvements to the local water-works plant.

Waverley, Iowa.—The people of this place will hold a public election, August 1, to settle the water-works question.

Hill City, Tenn.—There is a project being discussed to supply this place with water from the plant at Chattanooga. Water-Works Superintendent Wingfield, of the latter place, can furnish details.

Dayton, Wash.—At the recent city election the water-works proposition to bond the city for $55,000 was carried by a majority of 6 to 1, and only 45 votes were cast against it.

Keyport, N. J.—A special election will be held here on July 29, when there will be voted upon a resolution empowering the Board of Commissioners to raise by special tax the sum of $600, to be expended for experimental purposes, in order to ascertain whether or not a suitable water supply can be secured for the use of the people of the town.

Toledo, Iowa.—The question of issuing bonds for the purpose of establishing a system of water-works is to be submitted to the people of this place at an early day.

Houston, Tex.—It is probable that improvements will soon be made to the plant of the Houston Water-Works Company.

Lamar, Ill.—A water-works plant is to be established at this place by the Lamar Water Company. For particulars address J. Guinney, as above.

Salem, Mass.—Complaint is made of a shortage in the water supply of this city, and steps will probably be taken to remedy the difficulty.

Morgantown, N. C.—It is probable that the sum of $20,000 will be expended on establishing a system of water-works for this place. For particulars, address S. R. Collett, as above.

Babyylon, L. I.—The question of obtaining a water supply is now agitating the people of this place, and it would appear that determined steps in this direction are to be taken. At a public meeting of citizens, held a few days ago, the Board of Town Officers were present and the question was thoroughly discussed, the outcome being that a committee of three was appointed to investigate the matter. At the meeting a petition was offered from the Bay Shore Water Company offering to put water through the village for $750. The fact of a franchise having been awarded to the Long Island Water Supply Company, John Lockwood, President, a few years ago, prevented any decisive action, but as the opinion prevails that the franchise previously granted has become invalid on account of the said company's negligence to fulfill its contract, the committee was appointed to settle the matter. Dr. Arnold is one of the committee, and L. H. Fishel can also give information.

Crewe, Va.—The Crewe Land and Improvement Company has been incorporated here, with a capital of $100,000. Objects: to construct water-works, electric light plants, and gas works.

Quebec, Can.—It is reported that the water supply of this place is to be filtered and that an extensive plant for that purpose is to be established.

Marengo, Ind.—The *Post*, of this place, advocates establishing a system of water-works here.

Carthage, O.—Now that the preliminary steps have been taken it is probable that the construction of the proposed water-works system will commence.

Seattle, Wash.—The City Trustees have decided to purchase a Worthington Pump, with capacity of 1,250,000 gallons per day.

Petaluma, Cal.—The Petaluma Water Company is to build a reservoir on Sonoma Mountain, to hold 50,000,000 gallons of water.

Lumber City, Ga.—There is a project being discussed to establish a system of water-works at this place.

East Aurora, N. Y.—Town Clerk C. H. Luddington writes: "The vote on water-works has been had and stood 153 for and 6 against. Expect to commence surveying and making maps this week."

Chicopee, Mass.—Regarding the report that the water supply at this place was to be increased, Town Clerk John D. White writes; "Our water-works are owned by a private company, but as far as I can learn no steps have been taken to increase the facilities."

Gatesville, Tex.—Richard Potts writes from here as follows: "Our Water Company has just been permanently organized. We are waiting for our charter before going to work."

Monmouth, Ill.—It is probable that an election will be held at this place at an early date to decide the question of expending the sum of $25,000 on a water-works system.

Kimball, Tenn.—This place is to have water-works.

Knoxville, Tenn.—It is probable that immediate steps will be taken towards improving the water-works system at this place.

Fayetteville, N. C.—Reports say that the water-works committee is ready to receive proposals for the construction of water-works. For details address J. D. Neill, Chairman, as above.

Unionville, Conn.—The subject of building a reservoir and water-works at this place is being agitated.

Greensborough, Ala.—Reports say that a system of water-works is to be established at this place at once.

Florence, Ala.—It is reported that the sum of $200,000 is to be issued in bonds for the purpose of establishing a system of water-works.

St. Petersburg, Fla.—Reports say that a system of water-works is to be established at this place.

Quincy, Ill.—A 5,000,000 pumping engine is to be added to the local water-works plant.

Fulton, Ky.—The people of this place will hold a public election at an early day to decide for or against expending the sum of $25,000 on establishing a water-works plant. Edward Starks can furnish particulars.

Duquoin, Ill.—The people of this place held a public meeting recently to discuss the water-works question and the result was that a committee was appointed to look into the matter and report at another meeting to be held later. The clerk of the City Council can furnish particulars.

Amsterdam, N. Y.—Reports say that the local water supply is getting short, and that measures towards a proper remedy will be taken at once by the Water Commissioners.

Monroe, Wis.—Reports say that the water supply of this place is unfit to drink, and that a system of filtration is being considered.

Hicksville, O.—The following proposals for the construction of a system of water-works were received July 16, by J. D. Cook, Engineer, of Toledo, O.:

Contracts awarded to Bourbon Copper and Brass Works for hydrants at $25 each. Rensselaer Valve Mfg. Co. for valves at bid. Bingham & Taylor, Buffalo, N. Y., boxes, at bid.

Machinery and Boilers.—Holly Manufacturing Company, Lockport, N. Y.: No. 1, one C. N. C. H. D., 10x16x10x12, $2,850; two C. N. C. H. D., 10x16x10x12, $5,455. No. 2, one C. N. C. H. D., 8x12x8½x12, $1,825; two C. N. C. H. D., 8x12x8½x12, $3,360. No. 3, one H. P., 16x10x12, $2,190; two H. P., 16x10x12, $4,130. No. 4, two boilers set up complete, 54"x12", $2,670.

Hicksville Cart and Machine Company: No. 1, first engine C. N. C. H. D., 10x16x10x12, $2,775; second engine C. N. C. H. D., 10x16x10x12, $2,365. No. 2, first engine C. N. C. H. D., 8x12x8½x10, $2,375; second engine C. N. C. H. D., 8x12x8½x10, $1,875. No. 3, first engine H. P., 16x10x12, $1,975; second engine H. P., 16x10x12, $1,370. No. 4, first engine H. P., 14x8½x10, $1,825; second engine H. P., 14x8½x10, $1,190. No. 5, two boilers set complete, 54"x12", $2,240.

Gordon Steam Pump Company: No. 1, one engine C. N. C. H. D., 10x16x10x12, $2,815; two engines C. N. C. H. D., 10x16x10x12, $5,180. No. 2, one engine C. N. C. H. D., 8x12x8½x10, $2,410; two engines C. N. C. H. D., 8x12x8½x10, $4,280. No. 3, one engine H. P., 16x10x12, $2,015; two engines H. P., 16x10x12, $3,385. No. 4, one engine H. P., 14x8½10, $1,821; two engines H. P., 14x8½x10, $3,015. No. 5, one engine C. N. C. H. D., 12x18½x10¼x12, $2,970; two engines C. N. C. H. D., 12x18½x10¼x12, $5,490. No. 6, two boilers set complete, 54'x12', $2,415.

Hughes Steam Pump Company: No. 1, one engine, each 10x16x10x12, $2,410; No. 2, one engine, each 8½x14x8½x12, $2,050; No. 3, one engine, each 16x10x12, $1,710; No. 4, one engine, each 14x8½x12, $1 390; No. 5, two boilers set complete, 54"x12", $1,790.

Michigan Pipe Company, Bay City, Mich.: No. 1, two boilers complete and two pumps, 12x8½x12 (Holly pumps), $4,540; No. 2, two boilers complete and two pumps, 14x8½x12, (Hughes pumps), $4,670; No. 3, two boilers complete and two pumps, 14x8½x10 (Gordon pumps), $5,000.

William B. Pollock, Youngstown, O., two boilers and fittings, ex. setting, $1,100.

Mansfield Machine Works, Mansfield, O., two boilers and fittings, $1,284.

N. B.—Contract awarded to Hughes Steam Pump Company for two 14x8½x12 pumps, at $1,390 each complete, and two boilers set up complete, $1,790 for two, complete.

Pipe and Special Castings.—Lake Shore Foundry, Cleveland, O., 4, 6, 8 and 10-inch pipe, $25.55 per ton; specials, 2¼ cents per pound; total, $9,085.70. Dennis Long & Co., Louisville, Ky., pipe as above, $29.75 per ton; specials, 3¼ cents; total, $10,642.30. Addyston Pipe and Steel Works, Cincinnati, O., 4-inch pipe, $26.65 per ton; 6, 8, and 10-inch, $25.65 per ton; specials, 2⅜ cents; total, $9,285.92. Michigan Pipe Co., Bay City, Mich., total for all pipe laid, valves, hydrants and boxes, $13,426.65.

Pipe Laying.—Hicksville Cart and Machine Works, Hicksville, O., 4-inch, 17 cents; 6-inch, 19 cents; 8-inch, 23 cents; 10-inch, 26 cents; total, $4,305.87. J. J. Rumsey, Findlay, O., as above, 16 cents, 18½ cents, 23 cents, 26 cents; total, $4,143.45.

Building.—Daniel Weller, Hicksville, O., $1,386; Hicksville Cart and Machine Works, Hicksville, O., 18-inch foundation, $1,889; 36-inch foundation, $1,989.

Contract for pipe, etc., awarded to Lake Shore Foundry Co.; laying pipe to J. J. Rumsey; building to Daniel Weller.

Opelika, Ala.—It now seems probable that the water-works system projected will soon be established.

Piedmont Springs, Ala.—A small system of water-works is to be established at this place.

Galt, Ont.—It is proposed to add 86 hydrants to the local water-works system.

Statesville, N. C.—The people of this place have voted for water-works.

Malden, Mass.—A new brick pumping station is to be erected at the water-works, and additional machinery is to be established.

Norwalk, Conn.—Town Clerk L. Warner writes: "We are about to lay a new iron pipe for a distance of 2¼ miles."

Fulton, Ky.—This town is agitating the subject of water-works.

Ellsworth, Kan.—A system of water-works is to be established at this place by H. M. Hadley, of Topeka, Kan.

Lansdale, Pa.—It is probable that improvements will be made to the pumping machinery at the local water-works station.

Harvard, Ill.—Town Clerk P. E. Saunders writes: "An ordinance has been passed to grant a franchise to James H. Thompson, of Chicago, to erect and maintain a system of works in Harvard, and preparations are now making to complete contract and proceed with the work at once."

Garnett, Kan.—The people of this place have voted the sum of $30,000 for the purpose of establishing a system of water-works.

Quincy, Ill.—The Quincy High-Water Pressure Company has been incorporated at this place to establish a system of water-works.

Americus, Ga.—The people of this place have voted $25,000 for a system of water-works.

Mauch Chunk, Pa.—A new water company is to be formed at this place.

Water-Works.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Huntington, Ind.; Poughkeepsie, N. Y.; Washington, D. C.; Hinton, W. Va.; Goshen, Ind.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

LA SALLE, ILL.—The City Council has appropriated the sum of $30,500 to be expended on sewers during the year 1890. A letting will take place about August 5th.

GRAND RAPIDS, MICH.—The Board of Health has ordered the establishing of numerous additional sewers.

SALISBURY, N. C.—This city will soon hold an election to decide upon the issuance of $100,000 of bonds for a sewerage system.

KIMBALL, TENN.—Plans are being prepared for a system of sewers for this place.

NORWOOD, O.—Considerable sewer work is to be done at this place. For details address the Sewerage Commission, as above.

BRIDGETOWN, N. S.—A sewerage system is soon to be established at this place.

LOWELL, MASS.—The sum of $50,000 has been appropriated by the aldermen for the purpose of furthering the sewerage work.

SOUTHBOROUGH, MASS.—A new system of sewerage by downward intermittent filtration is being constructed for St. Mark's School, from plans furnished by the engineer, F. L. Fuller, of Boston.

TROY, N. Y.—Numerous sewer extensions are to be established in this city.

MARION, O.—The following proposals for furnishing 17,318 feet of 18-inch outfall sewers were opened July 18 by the Sewer Committee. The figures given are for the following quantities, respectively: Pipe, per foot; excavation and trenching, per foot; masonry, per cubic yard; manholes; covers for manholes; total. Bidders—Baird & Cain, Dayton, O., 45 cents, 65 cents, $6, $12.50 per M, $7.50 each; total, $19,179.80. Kelly Bros., Marion, O., 50 cents, 30 cents, $5, $25 per M, $9.37½ each; total, $14,021.90. Corcoran & Cornell, Toronto, O., 45 cents, 70 cents, no bid, $25 per M, $7.50 each; total, $20,055.70. Irvin & Maher, Greenville, O., 40 cents, 38$\frac{3}{10}$ cents, $5, $16 per M, $10 each; total, $13,683.88. Alexander C. Martin, Seneca Falls, N. Y.; 51 cents, 50 cents, $6, $15 per M, $12 each; total, $17,647.18. W. L. Porter, Lima, O., 40 cents, 39 cents, $3, $10 per M, $9.37½ each; total, $13,780.72. The contract was awarded to Irvin & Maher, Greenville, O., at their bid.

SEWERS.—See our Proposal Columns for information regarding sewers and sewer construction at the following places: Rogers Park, Ill.; La Salle, Ill.; Boston, Mass.; Washington, D. C.; Key West, Fla.; Galion, O.; Gravesend, L. I.; Cleveland, O.; Para, Brazil.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns

STOCKTON, CAL.—The sum of $25,000 has been appropriated at this place for the construction of bridges.

QUEBEC, CAN.—The Quebec Government has granted $510,000 towards the construction of an iron bridge at Valleyfield, Beauharnois County.

NEW IBERIA, LA.—An iron bridge is to be erected across the Teche River, at this place.

BURLINGTON, IA.—The Chicago, Burlington & Quincy has completed plans for the erection of a railroad bridge over the Mississippi River at this place.

DULUTH, MINN.—The letting of the contracts for the foundations and masonry for the drawbridge over Minnesota Point Canal, at Duluth, has been postponed on account of legal matters.

ST. LOUIS, MO.—Forest Park, this city, is to have two new bridges.

LLANO, TEX.—Reports say that a bridge is to be erected over the Llano River, at this place.

DAYTON, ORE.—The contract for a steel bridge over the Yamhill River, at this place, has been let to Hoffman & Bates, of Portland, for $14,000.

CALERA, ALA.—The Louisville and Nashville Railroad Company has awarded the contract for building the union bridge across the Coosa River, for $40,000.

COLUMBUS, O.—City Engineer Kinnear has completed the plans and profile of the High Street Viaduct, and is now at work preparing his estimate.

BOSTON, MASS.—The following proposals for the construction of the Federal Street bridge were opened, July 21, by the Engineering Department: Shaw & Miller, Somerville and Boston, $67,467; Alexander McInnis, Boston, $75,200; John Cavanagh & Co., Braintree, $79,500; W. H. Keyes & Co,, Boston, $79,668; J. N. Hayes & Co., Boston, $90,000; Benjamin Young, Chelsea, $94,000. Awarded to Shaw & Miller.

COLUMBUS, GA.—A $50,000 iron bridge is soon to be erected over the Chattahoochee River, by the Central of Georgia.

DARDANELLE, ARK.—The Dardanelle & Russellville Railroad will erect a pontoon bridge over the Arkansas River, at this place.

BRIDGES.—See our Proposal Columns for information regarding bridge construction at the following places: Mariette, Ga.; Wheeling, W. Va.; Roanoke, Va.; Toledo, Wash.; Waxahachie, Tex.

RAILROADS, CANALS, ETC.

NEW YORK.—A daily newspaper reports that the elevated railroad in New York City is to be extended "at one jump" from the present terminus of the Ninth Avenue line to Yonkers. Nothing authoritative, however, has been made public.

GAS AND ELECTRIC-LIGHTING.

TOWANDA, PA.—The Towanda Electric Illuminating Company will make extensive improvements to its plant.

COLLINSVILLE, ILL.—An electric light plant is to be established at this place by Louis Lumaghi and others. Proposed outlay, $25,000.

MERRIMAC, MASS.—The people of this place are still discussing the electric light question.

SPRINGFIELD, MASS.—Improvements are to be made to the plant of the local electric light company.

TICONDEROGA, N. Y.—An electric light plant is to be established at this place by the Ticonderoga Automatic Light Company. Estimated outlay, $14,000. Address John De Verennes, as above.

BINGHAMTON, N. Y.—The movement to establish an electric lighting plant at this place will probably end successfully. A committee of the Common Council now has the matter in charge.

NEW BRITAIN, CONN.—The Anglo-American Electric Light Company at Kensington, whose plant was burned out, will rebuild at once.

TOLEDO, IOWA.—There is talk of establishing an electric light plant at this place.

ATLANTIC, IOWA.—An electric light plant is to be established at this place.

WAYNESBORO, GA.—The question of electric lights for this place has been decided in favor of establishing a plant at once.

WINDSOR LOCKS, CONN.—The Directors of the Windsor Locks Electric Light Company held a meeting recently and voted to double the capital stock, making it $20,000. Improvements are to be made in the plant.

BEVERLY, MASS.—The people of this place are discussing the electric lighting question.

RUTLAND, VT.—A plant is to be established at this place by the Marble City Electric Light and Power Company.

BALLSTON SPA, N. Y.—Improvements are to be made to the local electric lighting plant.

SLATER, MO.—The people of this place have voted the sum of $7,750 for the purpose of establishing an electric lighting plant.

WARE, MASS.—The electric light station at this place, which was recently destroyed by fire at a loss of $12,000, is to be replaced immediately.

CREWE, VA.—It is now settled that the Crewe Land and Improvement Company will establish an electric lighting plant at this place.

BURRELL, PA.—The Burrell Gas, Water and Improvement Company has been incorporated here. Incorporators, Joseph P. Cappen, W. C Stewart, and others.

LAFAYETTE, IND.—The Lafayette Electrical Manufacturing Company has been incorporated here with a capital stock of $50,000. Incorporators, Dr. E. A. Hutchins, H. A. Hutson, and others.

OTTAWA, CAN.—Improvements will shortly be made to the plant of the Chaudiere Electric Light and Power Company at this place.

ELECTRIC RAILWAYS.—New electric railways will be established and improvements will be made to those already in operation at the following places: Whitinsville, Mass.; Littleton, N. H.; Cedar Rapids, Mich.; Asheville, N. C.; Albuquerque, N. M.; Duquoin, Ill.; St. John's, Ill.; Middletown, N. Y.; Tamah, Iowa; Toledo, Iowa; Cairo, Ill.; Naugatuck, Conn.; Waterbury, Conn.; Rockville, D. C.; Amsterdam, N. Y.; Brockton, Mass.

STREET-WORK AND PAVING.

SACRAMENTO, CAL.—The people of this city have voted to issue $100,000 worth of 5 per cent. bonds for street improvements.

HOUSTON, TEX.—Considerable street paving is to be done in this city at an early date. For particulars address Mayor Scherffins, as above.

CHATTANOOGA, TENN.—Numerous streets and avenues of this city are to be paved this season. Address the City Clerk for details.

NEWARK, N. J.—Bonds in the sum of $100,000 will be issued here for paving purposes.

HANNIBAL, MO.—The street-paving question is still being agitated at this place.

ALBANY, N. Y.—The following proposals for paving were opened by the Board of Contract and Apportionment, July 21: For paving Madison Avenue with Trinidad sheet asphalt from Lark Street to the intersection of Western Avenue. It will require 53,660 yards of asphalt, 16,000 feet of new curb, 290 feet of circular curb, 540 yards of repairing asphalt at street intersections, 120 elm trees, 15,400 for the 21 feet of new flag, gravel and sod sidewalk; 280 feet of old flag trimmed to shape and relaid; the credit price of 52,260 yards of cobble stone, and the credit price for $16,500 feet of old curb stone. The bids received were as follows: Barber Asphalt Company—Per yard for the first item, $3.25; second, 50 cents; third, 50 cents; fourth, 90 cents; fifth, $10 each; sixth, per foot, $2.45; seventh, $1.50 per square foot; eighth, 1 cent per yard; ninth, 1 cent.

Trinidad Asphalt Paving Company—First item, $3.15; second, 80 cents; third, 80 cents; fourth, $1; fifth, $5; sixth, $2.19; seventh, $1.18; eighth, 3 cents; ninth, 10 cents.

The bid of the Barber Company aggregated about $221,000, that of the Trinidad Company about $212,000. The contract was awarded to the Trinidad Company.

For paving Swan Street, from Elm Street to Irving Street, was awarded to Jacob Holler, whose bid aggregated 3,227.40.

LEXINGTON, KY.—The contract for paving Third Street has been awarded to the Southern Construction Company, of Tennessee, which agrees to macadamize the street, furnish the brick and lay them for $2.35 a square yard.

INDUSTRIAL.

THE Berlin Iron Bridge Company, East Berlin, Conn., has the contract for building the new foundry building for The Pratt & Cady Co. at Hartford, Conn. The side walls will be of brick, but the roof will be of iron and fire-proof boards designed by The Berlin Iron Bridge Company. The Pratt & Cady Co. will require three large cupolas, two large traveling cranes, and about 20 small jib cranes.

GOVERNMENT WORK.

WASHINGTON, D. C.—The following proposals for the work named were opened on the given dates by the Supervising architect of the Treasury Department:

New Orleans.—Alterations and foundations necessary to place a steel money vault in the west wing of the United States Mint Building at this place. Opened July 10. Advertisement of June 9. Bidders: John McNally, $4,782; Thomas O'Neill, $5,475; Louis C. LeCorgne, $7,125.

NEW CORPORATIONS.

COLUMBUS, IND.—The Louisville, Richmond and Dayton Railroad has been incorporated, with a capital stock of $4,000,000. The line will be 140 miles long.

PROPOSALS.

(Continued from page ii.)

PROPOSALS FOR SERVICE CONNECTIONS.—Office of Post Quartermaster, Fort Keogh, Mont., July 5, 1890. Sealed proposals in triplicate, subject to the usual conditions, will be received at this office until 12 o'clock noon, on the 5th day of August, 1890, and then opened, for furnishing all the labor required in making **SERVICE CONNECTIONS** with water mains at this post. Specifications, instructions to bidders, and blank forms of proposals will be furnished on application to this office. M. C. MARTIN, 1st Lieut. & R. Q. M. 22d Infantry; A. A. Q. M., U. S. A. 9

PROPOSALS FOR PLUMBING, ETC.—Depot Quartermaster's Office, David's Island, N. Y. H., July 1, 1890.—Sealed proposals, in triplicate, will be received until 11.30 A. M., WEDNESDAY, July 30, 1890, and opened immediately thereafter, for supplying and fitting up **BATH-TUBS, WATER-CLOSETS** and **URINALS** in basement of 1888 Brick Barrack at this place. Plans, specifications, general instructions to bidders and blank forms of proposals will be furnished to bidders on application to this office. The right to reject any or all bids is reserved to the United States. Captain J. MCE. HYDE, Assistant Quartermaster, U. S. Army, Depot Quartermaster. 8

TREASURY DEPARTMENT, U. S. LIFE-Saving Service, Washington, D. C., July 23, 1890.—Sealed proposals will be received at this office until 2 o'clock P. M. of THURSDAY, August 7, 1890, for the construction of a **LIFE-SAVING STATION** at Cold Spring, near Cape May City, New Jersey. Plans and specifications containing full information, and forms of proposal, can be obtained of the Collector of Customs, Philadelphia, Pa.; Superintendent of the Fourth Life-Saving District, Point Pleasant, New Jersey; Keeper Cold Spring Life-Saving Station, Cape May City, New Jersey; Superintendents of Construction, Life-Saving Stations, Atlantic and Lake Coasts; No. 24 State Street, New York City, and upon application to this office. S. I. KIMBALL, General Superintendent.

PROPOSALS.

SEWERS.—GALION, OHIO.

PROPOSALS ARE WANTED UNTIL NOON of August 20, 1890, for the construction of about 9,000 feet of **PIPE SEWERS.**

J. B. WEDDELL,
11 City Civil Engineer.

HUNTINGTON, IND., WATER-WORKS.

SEALED PROPOSALS WILL BE RECEIVED until noon of TUESDAY, July 29, 1890, by The Water-Works Manufacturing Company, of Huntington, Ind., for the following items for the Huntington **WATER-WORKS:**

One thousand five hundred and seventy-seven (1,577) tons of cast-iron water pipe, ranging from four (4) to sixteen (16) inches diameter.

Sixty-two thousand two hundred and seventy-six (62,276) pounds of special castings.

Eighty-four (84) six (6) inch double nozzle fire hydrants.

Fifty (50) four (4) inch double nozzle fire hydrants.

Ninety-seven (97) stop valves, from four (4) to fourteen (14) inches diameter.

Ninety-seven (97) stop boxes for above valves.

Laying of above Pipe, and setting of above Special Castings, Fire Hydrants, Stop Valves and Stop Boxes.

One brick Pumping Station.

One brick-lined circular Pump Well.

One timber Intake Pier.

One or two systems of Driven Wells.

Two (2) compound duplex direct-acting pumping engines, each of one million five hundred thousand (1,500,000) gallons daily capacity, together with two (2) return tubular boilers, sheet-iron chimney and all appurtenances necessary to complete said machinery.

Proposals must be made on the blank forms furnished by The Water-Works Manufacturing Company, and all legal formalities must be complied with to secure consideration of the proposals.

Plans for above work may be examined and blank forms of proposal and specifications can be obtained at the office of the Water-Works Manufacturing Company, Huntington, Ind., or the office of the Consulting Engineer, rooms 21 and 22 Glenn Building, Cincinnati, O.

The proposals must be sealed and addressed to The Water-Works Manufacturing Company, Huntington, Ind., and be indorsed with the name of the person, firm or corporation which make the tender, and be accompanied by a certified check, payable to the order of the Treasurer of The Water-Works Manufacturing Company, as follows:

Water pipe and special castings	$500
Fire hydrants	300
Stop valves	300
Pipe laying	500
Pumping station	300
Pump well	100
Intake pier	200
Driven wells	250
Pumping machinery	500

The company reserves the right to reject any or all proposals.

THE WATER-WORKS MANUFACTURING COMPANY,
WILLIAM MCGREW, Pres't.
JOHN W. HILL, Consulting Engineer,
Cincinnati, O.
HUNTINGTON, IND., June 30, 1890.

PROPOSALS
FOR
Key West Improvements.

OFFICE OF CITY CLERK,
KEY WEST, FLA., June 2, 1890.

SEALED PROPOSALS WILL BE RECEIVED by the City Clerk of KEY WEST, FLA., until 1st of September, 1890, for furnishing the necessary material and putting in an underground system of **SEWERAGE**; also for **GRADING** and **PAVING** the streets of said city and furnishing the material for same; also for furnishing and laying of water mains.

1st. All bids must be made upon the printed forms to be obtained from the City Clerk and inclosed in a sealed envelope, directed to the Board of City Commissioners, and marked on the outside of envelope, "Proposals for Key West Improvements."

2d. Each bid must be accompanied by a cash deposit or certified check of five hundred dollars, to be left in the hands of the City Clerk, subject to the conditions specified, as a guarantee of the good faith of the bidder.

3d. The city reserves the right to reject any and all bids.

4th. Bidders are requested to be present at the opening of the bids.

5th. Bidders are expected to bid separately on sewer system and material, on grading and paving of streets, and on furnishing and laying water mains.

6th. Plans and specifications can be seen at the office of the City Clerk, and at the office of Johnson & Flad, Consulting Engineers, Laclede Building, St. Louis, Mo.

WM. L. DELANEY,
8-10-12 City Clerk.

Proposals for Sewer Construction.

CITY OF POUGHKEEPSIE, N. Y.,
DEPT. OF WATER-WORKS AND SEWERS,
COMMISSIONERS' OFFICE, JULY 24, 1890.

SEALED PROPOSALS WILL BE RECEIVED at this office until noon of TUESDAY, August 5, 1890, for constructing about 1,500 feet of **VITRIFIED PIPE SEWERS** in this city.

Plans and profiles may be seen, and specifications, contract and forms of proposal, together with all necessary information, obtained on application at this office. All proposals must be made upon forms obtained at this office. The right is reserved to reject any or all proposals.

By order of Commissioners
CHAS. E. FOWLER,
9 Superintendent of Water-Works and Sewers.

PROPOSALS.

WATER-WORKS BONDS.

SEALED PROPOSALS ADDRESSED TO the City Clerk, will be received by the city of GALESBURG, ILL., until 6 o'clock P. M., August 4, 1890, for the purchase of **CITY BONDS** issued for water-works purposes in the sum of $100,000, said bonds to be dated October 1, 1890; $50,000 payable ten years after date, and $50,000 payable twenty years after date, all bearing interest at the rate of 4½ per cent. per annum, payable semi-annually. Both interest and principal payable at the Chemical National Bank in the city of New York.

Said bonds to be issued in denominations of $1,000 each.

The right is reserved to reject any or all proposals.

By order of the City Council.
9 J. C. STEVENS, City Clerk.

STREET PAVING.

SEALED PROPOSALS WILL BE RECEIVED for furnishing the materials and laying about 3,300 square yards of **GRANITE BLOCK PAVING** and 170 square feet of crossing stone, at the office of the Board of Road Commissioners of the city of Waterbury, City Hall, until 2 P. M. July 30, at which time and place they will be publicly opened and read. All bids must be upon proper blanks and must be accompanied by a bond for $200, with satisfactory sureties conditioned for the execution of the contract within five days after notice of its award.

A certified check for $200, payable to the city of Waterbury, to be deposited with the Board of Road Commissioners, will be received in place of the above bond. Specifications can be seen at the City Engineer's office, at which place blank forms of proposal can be obtained as well as further information.

By order of the Board of Road Commissioners.
F W. WHITLOCK,
Acting City Engineer.

PROPOSALS FOR CEMENT FOR THE District of Columbia.—Office of the Commissioners, Washington, D. C., July 15, 1890.—Sealed proposals will be received at this office until 12 o'clock M., on TUESDAY, July 29, 1890, for furnishing **CEMENT** for the Public Works of the District of Columbia. Blank forms of proposals and specifications can be obtained at this office upon application therefor, together with all necessary information, and only bids upon these forms will be considered. The right is reserved to reject any and all bids, or parts of bids.

J. W. DOUGLASS,
L. G. HINE,
H. M. ROBERT,
8 Commissioners, D. C.

PROPOSALS FOR THE CONSTRUCTION OF Sewers.—Office of the Commissioners, Washington, D. C., July 14, 1890.—Sealed proposals will be received at this office until 12 o'clock M., on THURSDAY, July 31, 1890, for constructing in the District of Columbia, **TERRA COTTA PIPE SEWERS**, Brick Sewers and Receiving Basins. M., on the 7th day of August, 1890, for all the **LABOR AND MATERIALS** required to complete the plumbing for the U. S. Court-House and Post-Office at CHARLOTTE, N. C., in accordance with the drawings and specification. Each bid must be accompanied by a certified check for $100. The Department will reject all bids received after the time fixed for opening the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be sealed and indorsed, "Proposal for Plumbing for the U. S. Court-House and Post-Office at Charlotte, N. C.," and addressed to JAS. H. WINDRIM, Supervising Architect. 9

PROPOSALS.

EAST RIVER BRIDGE.

Proposals for Plans for Improved Termini.

NOTICE IS HEREBY GIVEN THAT THE Board of Experts appointed to prepare plans for the improvement of the termini of the New York and Brooklyn Bridge in the two cities, will receive plans for the improvement of the termini from any person who may choose to submit them. Plans must be in writing and must be accompanied by drawings. No compensation will be made to any person for plans or drawings submitted, unless such plans or drawings, or some portion thereof, shall be adopted, and in such case the compensation for such plan or drawing will be fixed and determined by the Board of Trustees. The decision of the Board of Trustees upon all questions relating to compensation shall be final, and not subject to question or review.

Plans must be submitted to the Board of Experts addressed to C. W. Buckholz, Secretary, at the office of the Bridge Trustees, on or before September 1. Due notice will be given hereafter of the time and place where oral explanations will be heard.

Any information concerning the subject matter can be obtained at any time at the office of the Trustees of the Bridge.

JAMES HOWELL,
President.

JULY 19, 1890.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M., on the 15th day of August, 1890, for all the labor and material required for the **EXCAVATION CONCRETE FOUNDATIONS, STONE AND BRICK WORK** of the basement and area walls of the United States Custom House and Post Office building at EASTPORT, MAINE, in accordance with the drawings and specification, copies of which may be had on application at this office or the office of the Superintendent, at Eastport, Maine. Each bid must be accompanied by a certified check for $200. The Department will reject all bids received after the time fixed for opening the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be sealed and indorsed "Proposal for Stone and Brick Work, etc., for Basement and Area Walls of U. S. Custom House and Post-Office at Eastport, Maine," and addressed to JAS. H. WINDRIM, Supervising Architect. 9

BUILDING INTELLIGENCE.

BROOKLYN.

Saratoga av, w s, 40 n Atlantic av, 5 fr (br filled) dwells; cost, $10,000; o, a and b, W D Bogart.

Ellery st, n s, 250 e Marcy av, 4 fr (br filled) tens; cost, $28,000 all; o, L Beer and Mr Schaffner; a, B Holmburg.

Decatur st, s s, 22 e Patchen av, and Patchen av, e s. 82 s Decatur st, 5 br dwells; cost, $3,000 each; o, J B Booth; a, F W Ames; b, J N Booth.

Sumpter st, n s, 125 e Saratoga av, 6 fr (br filled) dwells; cost, $2,500; o and b, Wm H Booth; a J E Dwyer.

Covert st, n s, 275 e Evergreen av, 6 fr (br filled) dwells; cost, $2,500 each; o and b, Wm H Barton; a, same as above.

Van Voorhis st, n s, 270 w Evergreen av, 5 fr (br filled) dwells; cost, $3,000 each; o, Mary N McLean; a, G Nichols; b, E L J Bedell.

Bedford av, n e cor N 11th st, br bakery and storage; cost, $15,000; o, Christian Friedmann; a, C Rentz.

Broadway, n e cor Covert st, 4 br stores and tens; cost, total, $50,000; o, P Johnson; a, F Holmberg.

Adams st, w s, 75 s Myrtle av, br theater; cost, $40,000; o, Hyde & Behman; a, J De La Hayse.

Hamburg av, s w cor Harman st, 5 brick-filled tens; cost, total, $180,000; o, George Covert; a, Schrempf & Loeffler; b, H Loeffler.

Atlantic basin, South pier, near William st, fr storehouse; cost, $20,000; o, and b, Atlantic Dock Co; a, E W Perry.

Vernon av, n s, 165 e Lewis av, 4 brown and Euclid stone dwells; cost, each, $6,000; o, J B Booth; a, F W Ames; b, J N Booth.

McDonough st, n s, 300 e Stuyvesant av, 4 b s dwells; total cost, $15,000; o and b, Jas Cummisky; a, E Dennis.

N s Van Cott av. 25 e Eckford st, 2 br dwells; cost, $9,500 all; o, L Michael; a, H Vollweiler.

N w cor Bushwick and DeKalb avs, br Sunday School; cost, $32,000; o, Epworth M E Church; a, B L Gilbert.

149–51 Navy st, 2 br dwells; cost, $24,-000 all; o, Henrietta Fisk; a C Lincoln.

S s Nelson st, 144 e Hicks st, br dwells; cost, $9,000; o, Catherine Leaves; a, J W Bailey.

S e cor Broadway and Siegel st, fr dwell; cost, $7,000; o, M Heisberg; a, D Acker & Son.

W s Washington av, 28 n Gates av, br dwells; cost, $18,000; o, D H Fowler & Co; a, H Olmsted & Sons.

S s Van Voorhees st, 100 w Bushwick av, 3 fr dwells; cost, $12,000 all; o, F Ammonna; a, A D Vreeland.

N s 10th st, 197 w 8th av, 5 br dwells; cost, $32,500 all; o, J F Ranson; a, I D Reynolds.

N e cor Park and Nostrand avs: 2 fr dwells, cost, $14,000 all; o, Mr Sinson; a, H Vollweiller.

W s Saratoga av, 40 n Atlantic av, 5 fr dwells; cost, $10,000 all; o and a, W S Bogart.

S s Dean st, 165 w Brooklyn av, 4 br dwells cost, $24,000 all; o, J A Bliss; a, A E White.

N e cor Underhill av and Park pl, br dwell; cost, 9,900; o, City of Brooklyn; a, F Freeman.

507 Myrtle av, br dwell; cost, $7,000; o, S L Keeney; a, E Van Voorhees.

N s Joraleman, 111 e Henry st, br dwell; cost, $45,000; o, D Chauncey; a, C P C Gilbert.

N w cor Green and Flushing avs, 3 fr dwells; cost, $11,000 all; o, G Covert; a, Schrempf & Loeffler.

N s Sterling pl, 100 e Flatbush av, 4 br dwells; cost, $22,000 all; o, J Kowalinka; a, R Dixon.

E s Shepard av, 175 n Liberty av, 7 fr dwells; cost, $17,500 all; o, E D Yarber; a, C A Covie.

N s Woodbine st, 125 e Central av, 2 fr dwells; cost, $10,000 all; o, G Schwab; a, Wishert & Copeland.

N e cor Saratoga av and Hancock st, br dwell; cost, $10,000; o, J Crawley; a, D T Atwood.

N s 15th st, 97 e 7th av, br dwell; cost, $7,000; o, J J Ferry; a, J L Young.

BUILDING INTELLIGENCE.

BROOKLYN.—Continued.

N w cor Willoughby and Grand avs, br flats; cost, $12,000; o, E Judson; a, W M Coots.

W s Wythe av, 25 s N 11th st, 3 fr dwells; cost, $18,000 all; o, A Huesdadt; a, H Vollweiler.

E s Bedford av, 125 n Willoughby av, fr dwell; cost, $8,000; o, H F Burrough; a, W H Gaylor.

S s N 2d st, 125 e Graham av, 2 fr dwells; cost, $10,500 all; o, Estate of J Joerger; a, T Engelhardt.

N e cor Knickerbocker av and Hannan st, 4 fr dwells; cost, $18,000 all; o, J Bossert; a, J Platte.

S s Bergen st, 200 w Hopkinson av, 2 br dwells; cost, $8,000 all; o, F Kuchunk; a, F Holmberg.

N s Hancock st, 25 e Marcy av, br dwell; cost, $20,000; o, W G Randolph; a, P J Lauritzen.

MISCELLANEOUS.

ALBANY, ORE.—A hotel, to cost $50,000, is to be erected at this place by Charles Pfeiffer and others.

BALTIMORE, MD.—Charles nr North, 4 3-story br bldgs; o, D E Potter.

Maryland av nr 3d, 3 3-story br bldgs; o, same as above.

5th st nr Oak st, 7 3-story br bldgs; o, Chas A Flaggs.

BEATTYVILLE, KY.—M. Q. Wilson. architect, of Louisville, Ky., will make plans for a $15,000 hotel here.

BINGHAMTON, N. Y.—Cor High and S Water sts, br church; cost, $10,000; o, Methodist Society; a, J C Perry, supt; b, Chas Van Orden.

CANTON, O.—N e cor Court and Seventh sts, br bus block; cost, $8,000; o and a, J R Poyser; b, P Hahn & Wm Shoop.

CAMBRIDGE, MASS.—Brattle cor Mason, stone chapel; cost, $10,000; o. St John Memorial; a, Henry Vaughn; b, F L Whitcomb.

282 Broadway, fr addn; cost, $4,000; o, S J Davis; a, W E Clarke; b, E J Packard.

CHICAGO, ILL.—1–5 Emma st, br store and warehouse; cost, $10,000; o, Robert J Walsh; a, C Nelson; b, Jas Oliver.

318 Breill st, br flats; cost, $8,000; o, Mrs S J Grubbs; b, Jos Hodgson.

2–6 Colorado av, br store, offices, etc; cost, $65,000; o, Lowthers Hall; a, S M Randolph.

268 Racine av, br flats; cost, $8,000; o, E T Dodson; a and b, F W Thomson.

85 Fowler st, br flats; cost, $10,000; o, A B Wait; a, W Ohlhaber.

Adams and Dearborn sts, remodeling and addition to office bldg; cost, $350,000; o, Marquette Building Company: a, Holaboid & Roche; b, Geo A Fuller & Co.

131–37 w Erie st, br flats; cost, $25,-000; o, J Cook; a, J F and J P Doerr; b, E Bushner.

422–24 s Paulina st, br flats; cost, $8,000; o, Andrew Wenigar.

1250 Washington boul, br dwell; cost, $8,000; o, Agner Bros; a, C A Weary.

Sherman and 66th sts, br flats; cost, $50,000; o, McCauley & Swartout; a, J Eighton; b, C A Lake.

4624 Emerald av, br dwell; cost, $8,000; o, D E Hartwell; a, Beman & Parmentier.

Peoria and 56th sts, br dwell; cost, $14,-000; o, J L Swan.

367 Cleveland st, br flats; cost, $12,000; o, M Vogalgerang; a, Fromann & Gibsen; b, H Mueller & Bro.

69 Grant place, br flats; cast, $8,000; o, Albert Anbach; a, B F Werges; b, C Hageman.

733 w Jackson st, br flats; cost, $9,000; o, Jas S Kidd; a, J M Van Osdel & Co; b, Jas S Price.

2977–79 Dearborn st, stone and br church; cost, $35,000; o, Bethel African Methodist Episcopal Church; a, E H Turner; b, E Slatery & Sons.

682 w 18th st, br addition: cost, $8,000; o, F Sonnberg; b, M Schultz.

178 n May st, br flats; cost, $8,000; o, Chas Jesen; a, G Isaacson; b, G Gilbert.

BUILDING INTELLIGENCE.

CHICAGO, ILL.—609–11 w 12th st, br addition; cost, $8,000; o, Jno Schwyer; a, Hy Hildinger; b, Pratt & Nieterink.

1314 Michigan av, br dwell; cost; $23,-000; o, Geo Brandt; a, Burnham & Root; b, N McMillan.

Jackson, Clark and La Salle sts, addition to Grand Pacific Hotel; cost, $32,000; o, Drake, Parker & Co; a, W W Boyinglon; b, Mortimer Bros.

Bliss, Hickory and Cherry sts, malt house; cost, $48,000; o, Bemis & Curtis Malting Company; a, S Lindreth; b, A Lanquist.

756 Washington boul, br flats; cost, $12,000; o, Jacob Kramer; a, Geo Gruessing; b, Geo Lehman & Sons Co.

118–24 State st, br addition; cost, $13,-000; o, Chas W Partridge; a, J J Egan; b, Thos Nicholson.

4528 Drexel st, br dwell; cost, $17,000; o, N W Harris; a, C S Frost, b, Angus & Gibdele.

4536–40 Lake av, br dwell; cost, $14,000; o, Geo H Bliss; a, W H Drake; b, J Stacey.

St. Lawrence and 71st st, br dwell; cost, $11.000; o, W E Palmer.

79–81 44th st, br dwell; cost, $12,000; o, A J Toolen.

166 buildings costing less than $7,000 each.

CINCINNATI, O.—Liberty st and Dalton av, 2-story br factory; cost, $8,000; o, Illinois Leather Co; a, Kukertz & Pfeiffer.

Storrs and Burns sts, 3½-story br store and dwell; cost, $7,500; o, Henry Schultz; a, L P Hague.

4th st nr Broadway, remodeling Christ's Church; cost, $25,000; c, W H Stewart's Sons; a, W Martin Aiken.

DAYTON, O.—Nothing over $7,000 in value to report.

DETROIT, MICH.—N side Joy st, bet 3d and 4th sts, 2½-story br res; cost, $7,000; o, John H Johnson; a, A C Varney & Co; b, not let.

S w cor Terry av and St. Antoine st, 2-story br and s res; cost, $7,000; o, Robt J Wilson; a, E A Walshe & Son; b, not let.

DENVER, COL:—Wynkoop st, bet 15th and 16th sts, br warehouse; cost, $15,000; o, L L Higgins; a, F D Robinson.

1st av, bet Clark and Water sts, br dwell; cost, $8,500; o, H Walker; a, Barressler Bros.

17th st, cor Stout st, stone bldg; cost, $1,000,000; o, Denver Equitable Building Company; a, Andrews, Jaques & Rantol.

13th av, bet High and Williams sts, br terrace; cost, $12,000; o, W H Merideth.

DRACUT, MASS.—4-room school house; address Michael Collins; b, not let.

4-room school house; address Percy Parker; b, same as above

EASTON, PA.—Northampton st, an 8-room br school bldg; cost, $18,000; o, Board of Control; a, John M Stewart.

JACKSON CITY, TENN.—M. Q. Wilson, architect, of Louisville, Ky., will make plans for a $13,000 hotel here.

LIVERMORE, CAL.—A church, to cost $15,000, is to be erected at this place.

LONDON, ONT.—Addns to and remodeling of stone cathedral; cost, $50,000; o, St Paul's Church (Church of England); a, Spier & Rohns, Detroit, Mich; b, not let.

LOWELL, MASS.—Western av, 5-story br mill; 75x120; o, A S Russell; b, not let.

MILWAUKEE, WIS.—Oneida and River st, power house; cost, $60,000; o, Edison Electric Light Co; a, E T Mix & Co; b, F Niezerowski.

Commerce st, power house; cost, $20,000; o, Milwaukee Light and Power Co; a, Charles Kirchhoff; b, Charles F Ehlers.

Clinton st, machine shop; cost, $8,000; o, E P Allis Co.

MILFORD, N. H.—Br library bldg; address Mr H H Barber; b, not let.

MONTCLAIR, N. J.—Nothing over $7,000 in value to report.

BUILDING INTELLIGENCE.

MINNEAPOLIS, MINN.—Cor Grant st and 1st av, stone church; cost, $100,000; o, Centenary M E Church; a, W J Hayes; b, H Downs & Son.

2836–38 8th av S, br stores and flats; cost, $16,000; o, a and b, W H Lang.

110–16–18 2d st N, br stores, cost. $24,-000; o, Whetmore & McMillan; a, F A Clark; b, J Condon.

Cor of 8th av N E and 2d st, br hall and school; cost, $10,000; o, St Anthony of Padua; a, F G Corser; b, Kilroe Bros.

4th av N bet 3d and 5th st, 2 br freight houses; cost, $29,000; o, Minneapolis & St Louis Ry Co; a, W B Hixson.

Cor of 8th av S E and 4th st, stone church; cost. $31,000; o, Andrew Presbyterian Church; a, James Carlisle & Son.

Cor Jackson st and 25th av N E, 2-story br ten; cost, $21,000; o and b, S S Farnham; a, Jas S Record.

3d st N bet 18th and 20th, 2-story brick police station; cost, $15,000; o, city of Minneapolis; a, Jas H Record; b, Foster & Smith.

2220–22 Aldrich av, fr apartment house; cost, $8,000; o and b, A D Alrich; a, J Jepson.

OWATONNA, MINN.—The Commissioners of Steele County have voted to build a $40,000 Court House in this city. Work will be begun next spring.

PORTLAND, ORE.—Mr C H Lewis is about to erect a large brick warehouse on Fourth and D sts for the Overland Warehouse Company.

POTSDAM, N. Y.—Messrs. Ives Brothers will soon begin the erection of two stores, stone fronts, three stories; furnace or hot water heating; cost about $10,000; a, J P Johnston, Ogdensburg, N. Y.

PROVIDENCE, R. I.—Humbolt av, fr dwell; o, John M Rounds; b, Whitaker & Smith.

Parade st, fr dwell; o, Mrs Edward R Crowell.

Pitman st, br and fr bus block; o, Manville Manufacturing Co.

Station st, 3 fr cottages; o, Josephine H White; b, A A White.

Ship and Richmond sts, br bus block; o, Delphine J Lanard.

SALT LAKE CITY, UTAH.—Cor State st and Second South st, 3-story fr business bldg; cost, $60,000; o, G H Holmes; a, Huddart & Jacobson.

Main st, bet South Temple and First South sts, 5-story stone office bldg; cost, $80,000; o, Cutler, Hardy & Young; a, R Bowman.

SPRINGFIELD, O.—Nothing in value over $7,000 to report this week.

SPRINGFIELD, MASS.—Elm st, br block of tens, 3 stories; o, Mrs E C Hawes; b, C L Shaw.

SHORT CREEK, O.—4 fr residences; cost, $2,500; o, F B Wilson; a, Jos Leina; b, not given out.

ST. LOUIS, MO.—8th st and Chauteau av, br store and flats; cost, $10,000; o, E A Maime; b, J Schenck.

Page and Prairie avs, br dwell; cost, $10,600; o, C D Jordan; b, Meehan & Cregan.

4th and Elm sts, front to store; cost, $16,800; o, A Busch; b, C Killerman.

VANCOUVER, B. C.—Plans have just been adopted for the erection of a temperance hall and coffee tavern in this town, to cost $30,000. Address Charles E Hope, architect and engineer, Vancouver.

WILKES BARRE, PA.—Nothing to report this week costing over $7,000.

WORCESTER, MASS.—A public school building, to cost $125,000, is to be erected at this city.

WHEELING, W. VA.—North Market st, br office bldg, with stone trimmings; cost, $50,000; o, Peabody Insurance Co; a, E Franzhein; b, not let.

2 12th street, hotel addn; cost, $7,000; o, Hotel Windsor; a, Jos Leiner; b, D Brooks.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22.
NUMBER 9.
PUBLISHED EVERY SATURDAY.
277 PEARL ST., NEW YORK.

NEW YORK, AUGUST 2, 1890.
LONDON, AUGUST 16, 1890.

SINGLE COPIES, TEN CENTS.
Subscription, $4.00 per year in advance, post paid. IN AMERICA.
SINGLE COPIES SIXPENCE.
Subscription, 20s. per annum in advance, post paid. IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street*, *New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.
20*s*. in GREAT BRITAIN. Other Foreign Countries $5.
Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $5; China, Japan, Sandwich Islands, Mexico and Cuba, $5; South America, $5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

STEEL FOR WATER AND OTHER PIPES.

AT the Chicago meeting, last May, of the American Water-Works Association, the question was asked which would be the best material for water-pipes—steel, cast iron, or wrought iron, irrespective of cost, the design evidently being more particularly to bring out whatever data there might be bearing on the use of steel pipes. Unfortunately, however, facts and figures relating to the subject seemed to be entirely lacking, or, what appears more probable, were too meagre to admit of anything like definite conclusions. At any rate, no expression of opinion was volunteered.

It is of interest, therefore, to note some of the developments in this line more recently recorded in England, and referred to in London *Engineering* a short time ago. According to the account there given, substantial progress towards the adoption of steel for the manufacture of pipes has been made during the past year. Mr. James Riley, a prominent engineer, more distinctly associated with steel construction, has been making efforts of a more or less tentative character to secure the adoption of this metal for the purpose, and has overcome what is repsented as the only technical difficulty—the welding of the tubes.

Some time ago Messrs. A. & J. Stewart, Glasgow, and the Steel Company of Scotland, in conjunction, supplied tubes of steel for carrying the water over the Tay Bridge, this being the first illustration of their use in Great Britain. These pipes were welded by Messrs. Stewart, and were fitted with Riley's patent socket, and completed by the Steel Company. They have proved very satisfactory. Tenders have been put in recently for 1,600 tons of steel water mains of large size for the Sydney Water-Works. Estimates and tenders have been made within the last year or two for several very large quantities, requiring from 100,000 to 150,000 tons of steel, but, as was the case on the introduction of steel for ship construction, the progress is very slow. When the strength of steel is contrasted with that of cast iron, of which those large water mains are usually constructed, it will be at once apparent that a great reduction can be made in the thickness and consequent weight of the metal required for the purpose. For transportation, too, the question of freight is a consideration. As an indication of this it may be mentioned that in a contract now in course of execution, the material for which is supplied by one of the steel companies in Scotland, for 20 miles of water main for Mexico, the sheets are not more than one-tenth of an inch in thickness. The fear of corrosion is not shared in by the engineers of this scheme, for having had experience for a number of years with the behavior of wrought iron for this purpose, they have had no hesitation in adopting the stronger and better metal, steel. This main for Mexico is riveted, and the connections are the same as those used in the Tay Bridge pipe. It is under contemplation to make provision in the west of Scotland for executing contracts for steel piping at a more rapid rate than is now possible.

We would remark here that so far as the welding of steel tubes is concerned, this has been successfully accomplished also in the United States. Another difficulty, however, is the fighting down of the prejudices against steel for such tubes, and the determination whether or not these prejudices have a good, practical foundation. At present there is nothing approaching a consensus of opinion on this point.

RECENT COMPRESSED AIR POWER SYSTEMS ABROAD.

DURING the past few years developments in the line of power distribution from central stations have been remarkably rapid, and experience has proved, very conclusively in some cases, that notwithstanding the heavy cost of construction and expense of maintenance of such plants, there is still a fair margin for profit in their working. Steam and hydraulic power systems afford more familiar examples of what can be done in this field, and their success has, in a great measure, encouraged the undertaking of other work involving the same general principles.

Among this must be classed the various installations for compressing and distributing air through underground pipes, probably the first of which was the plant of the Birmingham Compressed Air Power Company in England. Several others followed in rapid succession, notable among them the system of the widely noticed Popp Company at Paris, the main features of which were outlined in our issue of April 12, 1890.

The degree of favor which this system has obtained is best shown by the various Popp projects which are now on foot, not less than four German cities—Würzburg, Bamberg, Fürth, and Offenbach, having the system under consideration. The German engine and machinery firm, August Riedinger & Co., of Augsburg, is at the head of the enterprises. It has been ascertained that at Würzburg the company is assured of a demand for at least 400 horse-power, and at Bamberg of one for 600 horse-power. At Fürth a contract has already been entered into according to which Messrs. Riedinger & Co. will have a monopoly of the business for a term of 40 years. The city will receive annually a certain sum per mile of pipe in operation, and, in addition, will participate in the profits as soon as these will exceed 6 per cent. of the invested capital. After 11 years the city, further, will have the option of buying the plant, the price to be not less than 15 per cent. above the original cost of installation. Twenty-three hundred horse-power have already been subscribed for. The plant is to be ready for operation within two years. At Offenbach practically the same contract is about to be made, and a demand for at least 1,000 horse-power is assured. Two years is here also specified as the time limit for the completion of the plant, but efforts will be made to have everything ready for work next summer. Messrs. Riedinger & Co. are making efforts also to supply the city of Sachsenhausen from their Offenbach station.

It is self-evident that the construction of these several plants calls for a considerable money outlay, and that this would not be readily entered into were not success reasonably well assured, both from practical and financial points of view. In this country nothing, so far as we know, has yet been done in this field, at least so far as power supply in cities is concerned. The peculiar advantages of the system, however, entitle it to recognition.

CEMENT TESTS IN FRANCE.

In obtaining cement for the harbor works at Boulogne and Calais, France, the plan has been followed, since 1885, of not only subjecting the cement to certain tests before acceptance, but of exercising a careful supervision over its manufacture and instituting a series of analyses of the raw material used.

A ministerial decision, dated November 3, 1886, has placed all this work in the hands of the maritime office at Calais, and authorized the establishment of a chemical-testing laboratory at Boulogne for analyzing the raw materials of cements, under the supervision of the Chief Engineer of this office. The laboratory began its work in the early part of 1887, and, though mainly chemical in character, is fitted up with suitable apparatus for carrying out mechanical tests of cements. An extract from a report to the French Cement Commissioner, prepared by W. R. Feret, Chief Engineer of the laboratory, and published in the *Annales de Ponts et Chaussee* for March, 1890, gives an account of some of the work done during the last three years.

The subject is treated of in considerable detail under the following three heads:

(1) Chemical composition of cement; (2) cement grinding; and (3) preservation of cement before use.

Under the first of these heads Mr. Feret considers successively the character of the raw material, calcining, setting properties, specific gravity and resistance tests, etc., and gives elaborate tables of results obtained in the laboratory practice. Under the head of grinding, the much-discussed question as to the degree of fineness to which cement should be ground is taken up. Several methods of determining the degree of fineness are described, and the influence of the degree of fineness on the properties of cement is considered. The most economical degree of grinding, from the consumers' standpoint is also discussed.

Under the third head, the preservation of cement before using, different methods of preservation are briefly described. Artificial ventilation of cement, and the changes which it undergoes on being exposed, in thin layers, to moist air are dwelt upon at some length, and results of tests of cements so exposed for varying periods of time are given.

The various points discussed and experiments described all have a direct bearing on the intrinsic quality of cement. This, however, as Mr. Feret remarks, is not the only point to be considered in a study of the material. A question not less important is that involving the degree in which the properties of cement mortars are influenced by methods of manufacture and of use. This also has been studied to some extent at the laboratory, but the results will not yet admit of definite conclusions as the experiments made are of comparatively recent date and the element of time is of importance.

Mr. Feret's notes, even though forming but an extract from his complete report, are much too comprehensive to admit of reproduction here. Their study in the original, however, will prove both interesting and valuable.

POOR PAVING WORK IN NEW YORK.

Not alone are the granite paving block specifications for the streets of New York being grossly ignored in the matter of size of block, as shown by some of the figures published in The Engineering and Building Record last week, but inferior material is also being extensively used.

Thus the result of recent inspections on the part of the Finance Department has been that fines have been imposed as follows:

Matthew Baird, contract to pave Hudson Street from Beach to Spring Street, used limestone instead of gneiss in laying 2,000 square yards; Comptroller deducted $200 from contract money

William J. Clark, contract to pave Wall Street from Broadway to Nassau Street, used limestone instead of gneiss to lay 236$\frac{9}{10}$ square yards of foundation; Comptroller deducted $23.69.

Charles Guidet, contract to pave Leonard Street from Broadway to Hudson Street, used limestone instead of gneiss to lay 598 square yards of foundation; Comptroller deducted $59.80. Contract to pave Laight Street from Canal to Greenwich Street, used limestone instead of gneiss to lay 769$\frac{8}{10}$ square yards of pavement; Comptroller deducted $76.98. Contract to pave Broad Street, Exchange Place to Pearl Street, used limestone instead of gneiss to lay 782$\frac{1}{10}$ square yards of pavement; Comptroller deducted $78.21. Contract to pave Reade Street, used limestone instead of gneiss to lay 750 square yards of foundation; Comptroller deducted $75.

Thomas Gearity, contract to pave Lexington Avenue from Thirty-fourth to Thirty-fifth Street, used limestone instead of gneiss to lay 1,500 square yards of foundation; Comptroller deducted $150.

Bernard Mahon, contract to pave Spring Street from Bowery to Broadway, used limestone instead of gneiss to lay 275 square yards of foundation; Comptroller deducted $27.50.

James Pollock, contract to pave Cedar Street from Broadway to Greenwich Street, used limestone instead of gneiss to lay 676$\frac{7}{10}$ square yards of pavement; Comptroller deducted $67.67. Contract to pave Platt Street from Pearl to William Street, used limestone instead of gneiss to lay 750$\frac{6}{10}$ square yards of foundation; Comptroller deducted $75.06.

THE EFFECT OF VEGETABLE AND ANIMAL ORGANISMS ON THE TASTES AND ODORS OF WATER SUPPLIES.

J. M. Diven, of Elmira, N. Y., Secretary of the American Water-works Association, has just sent out the following circular:

> At the Chicago meeting the following resolutions were passed, to which we would earnestly solicit your attention.
>
> *Whereas*, The relations which exist between the growth of vegetable and animal organisms and the offensive tastes and odors frequently affecting water supplies are very imperfectly understood, but at the same time of great practical importance to water engineers and the public generally; therefore,
>
> *Resolved*, That it is the sense of the Convention that the investigation of this topic is one which lies within the particular scope and objects of the American Water-Works Association, and that a committee charged with the conduct of this investigation should be appointed, and requested to report at our next annual meeting.
>
> The committee consists of L. J. LeConte, Oakland, Cal.: L. H. Gardner, Superintendent of Water-Works, New Orleans, La.; and Albert R. Leeds, Stevens Institute of Technology, Hoboken, N. J., acting as chairman. While the meeting to which this committee reports is not held until April of next year (in Philadelphia), yet, inasmuch as the waters are most affected by the troubles referred to during the summer season, the committee is desirous of beginning its labors forthwith. To this end the committee invites correspondence with the superintendents and engineers of all water supplies which have at any time been contaminated by the growth and decay of organisms. All specific and precise information which they can give relating to the date, season, duration, nature, extent and results of these troubles in relation to their particular water supplies will be of value.
>
> Moreover, in case a proper sample, which should be of not less quantity than two gallons, is sent by express prepaid, to the chairman of the committee, a biological and chemical analysis will be made and the results communicated to the sender at the earliest practicable date.
>
> The information obtained in these various ways will be condensed and incorporated in the report to the association next May.
>
> Write speedily, and help in starting this very important piece of work.

THE STEVENS INDICATOR.

The July number of *The Stevens Indicator*, which has just been issued, contains, besides other interesting articles, one on "Fabrication of 12-Inch Mortars," by A. A. Fuller and F. N. Connet. It deals with the 12-inch breech-loading mortars now being built for the Government by the Builders Iron Foundry, of Providence, R. I. The process of manufacture is described in detail, and a number of illustrations are given.

Professor J. E. Denton contributes an article entitled, "Notes on the Action of Lubricants," in which the matter of internal engine friction is specially considered.

C. W. Thomas continues his paper on "Cable Traction as Applied to Elevated Railroads," commenced in an earlier issue, and describes and illustrates various cable gripping devices.

F. E. Idell contributes a note on "The Identification of Dry Steam," with special reference to a recent boiler test, and Professor H. A. Wood explains "A New Method of Extracting Cube Root." A lecture on "The Examination of Lubricating Oils," delivered by Professor Thomas B. Stillman before the Senior Class at Stevens Institute, is also given.

PUBLICATIONS RECEIVED.

Heat; the Warming and Ventilation of Buildings. By John H. Mills. Two volumes; pp. 604.

NOTES.

Rrcent tests made in connection with the underground steam pipes in New York by Dr. Cyrus Edson, of the New York Health Board, show that the temperature in some manholes ranged from 140 degrees to 162 degrees, while the temperature in manholes remote from the pipes was between 71 degrees and 76 degrees. Water in the Croton pipes near the steam pipes was found to be heated to 120 degrees at points where it ran into buildings. In vaults under Broadway buildings the air had been heated to 140 degrees. The question just now is whether the sections shall be cut off altogether.

The first annual convention of the United Association of Journeymen Plumbers, Gas Fitters and Steam Fitters opened in Pittsburg on July 28 in their hall, Market and Water Streets, about 50 delegates being present. P. J. Quinlan, of Boston, presided. The apprenticeship question will be brought up during the convention. This question caused the strike of the Pittsburg plumbers some weeks ago, and it remains with the convention to settle the matter. The plumbers are working at present, pending such a settlement. It is likely that the eight-hour question will also come before the convention. Charles Signor, delegate from St. Louis, said that eight hours would certainly be established among the plumbers before long. Many of them have the eight-hour day now.

The State Railroad Commission has approved the application of the Coney Island and Brooklyn Railroad Company for permission to change its motive power from horses to electricity upon that portion of its road in Sea Breeze Avenue, from East Fifth Street to West Fifth Street, on condition that the rate of speed of cars shall not exceed that to be determined by the Highway Commissioners of Gravesend, and that no car shall be operated with less than two men in charge.

The three Brooklyn surface railroad companies which control most of the street car lines in Brooklyn have decided to adopt as a motive power the overhead system of electric wires. They are the Brooklyn City Railroad Company, Atlantic Avenue Company, and Jay and Smith Street Company. The applications of all the lines for permission to use electricity are now before the Common Council, and the consent of the property owners along the various lines is being solicited.

In a recent issue of *La Semaine des Constructeurs* attention is again directed to the rapid deterioration of lead when in contact with oak timber. Gutters and parts of roofs are frequently much damaged by the chemical action set up by such contact. The Société du Nord cites a case where a lead gutter resting on oak supports was destroyed in a few years, the lead being completely oxidized by the combined action of the wood acid and moisture.

OBITUARY.

Samuel Whitney, head of the firm of Whitney Brothers, founder of the town of Glassboro, N. J., and of the great glass manufacturing business there, died at Cape May on July 29. He was 73 years old and one of the best known glass manufacturers in the country.

PERSONAL.

Charles L. Weber, City Engineer of East St. Louis, will sail for Europe in a few weeks, to be absent until next Spring.

John P. Force, civil engineer, has been appointed Engineer in Charge of Street Improvements and Sewers at North Baltimore, O.

Willard Beahan, M. Am. Soc. C. E., was recently appointed Engineer of Maintenance, St. Louis, Mo., with headquarters at the City Building.

Onward Bates, Engineer and Superintendent Bridges and Buildings Chicago, Milwaukee and St. Paul Railway Company, has removed his office from Milwaukee to Rand, McNally & Co.'s building, Chicago.

J. W. Holmes, Consulting Engineer, who has been in charge of the Paducah, Ky., Water-Works for three or four years past, has recently made a contract for five years to serve as Chief Engineer of the above-named works.

ENGINEERING SOCIETIES.

THE BOSTON SOCIETY OF CIVIL ENGINEERS had an excursion to Fort Warren, in Boston Harbor, on Saturday, July 26, by invitation of Col. S. M. Mansfield, of the U. S. Engineering Corps of this district. There were about 50 members of the Society in the party. The fort was inspected and an explanation given of the new method of coast defence by submarine mines.

A PRELIMINARY notice has been issued by Secretary Hutton, of the American Society of Mechanical Engineers, announcing that the twenty-second meeting of the Society will be held in the city of Richmond, Va. It will probably begin November 11. Intending authors of papers are requested to send in the titles of papers now. Manuscripts of papers, especially if illustrated, are desired before, or in any case not later than, October 1.

The second addition of the Society's catalogue for 1890, corrected to July 1, has been issued.

ARCHITECTURAL LEAGUE COMPETITION.

MEMBERS of the Architectural League are at present much interested in a competition over designs for the proposed new building of the American Fine Arts Society. The designs are to be sent in under cipher to the Committee on Site and Plans, of which Edward H. Kendall is Chairman, and whose Secretary, H. J. Hardenbergh, has just sent out the invitations to architects in the League to enter the competition.

The conditions for the competition were arranged at a meeting of the committee held June 17. A jury of award was appointed, consisting of President Chase, of the Society of American Artists, President Sturgis, of the Architectural League, President French, of the Art Students' League, President Butler, of the American Fine Arts Society, Chairman Marquand, of the Board of Trustees of the Gift Fund of the American Fine Arts Association, and Chairman Kendall, of the Committee on Site and Plans. Should there happen to be a disagreement or a tie vote, Richard M. Hunt is to become a member of the jury.

The designs are all to be submitted by September 1. The jury will proceed to select three, and then a second competition will be arranged, in which the authors of the three selected designs will take part. The one of the three whose design is finally chosen, will be awarded the contract for erecting the building at the regular commission fixed for such work by the schedule of charges of the American Institute of Architects. The authors of the other two designs will be paid $200 each. The jury to make the award in the second competition will consist of Messrs. Chase, Sturgis and Butler.

The proposed new building will furnish quarters for the Society of American Artists, the Architectural League, and the Art Students' League. It is to cost $160,000 and to be fire-proof. Sketch plans of the building are sent to competitors. The building is to be so planned that the Society of American Artists shall have at least 1,750 square feet of floor space, the Architectural League at least 2,500, and the Art Students' League at least 10,000.

THE NEW CROTON AQUEDUCT.

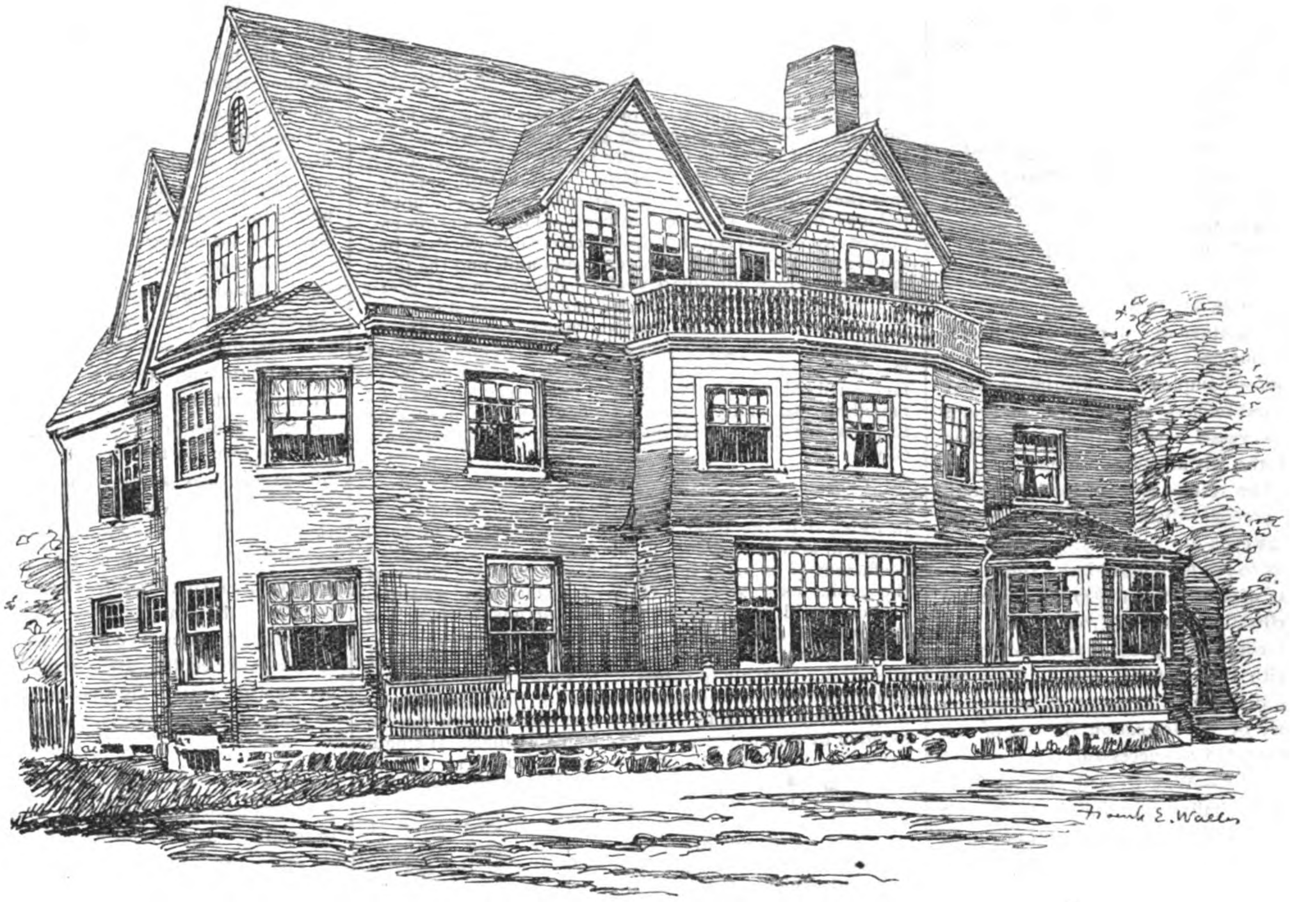
THE first official report since the new Croton Aqueduct opened was submitted on July 30 to the Construction Committee of the Aqueduct Board by Chief Engineer Fteley. In it he explains in detail the progress of the work and the amount of water supplied to New York City daily, which he places at 50,000,000 gallons. As to the alterations which it is proposed to make, and the defects which are to be remedied he makes some suggestions. He proposes to overcome Commissioner Gilroy's objections against cutting off the supply while the repairs are being made by doing the work in sections. He also submits the full correspondence on the subject, and says it is a matter of congratulation that, despite the leakage at Shaft 19, the aqueduct appears to be in excellent condition.

"By agreement with the Commissioner of Public Works," said Mr. Fteley in his report, "the gates at Croton Dam were opened on Saturday evening, July 12, to the extent of furnishing 38,000,000 per day. The water was retained for a while in the aqueduct, as everything was not in readiness in the lower part, and it was desired to let the water in slowly at first. On Tuesday, July 15, the gates were opened at 6 A. M. at the One Hundred and Thirty-fifth Street gate-house, and the water reached the Central Park Reservoir through the five 48-inch pipes. Since that day the flow from the Croton gate-house has been changed from time to time in accordance with the requests made by the Chief Engineer of the Department of Public Works, as per accompanying schedule.

"Schedule of the flow at Croton Dam:

"July 12, 6 P. M., 30,000,000 gallons; July 16, 6.30 P. M., 50,000,000 gallons; July 19, 9.15 A. M., 75,000,000 gallons; July 24, 9 A. M., 50,000,000 gallons; July 30, flow continues at the rate of 50,000,000 gallons per day.

"When letting the water in for the first time the aqueduct was watched with great care, more particularly in the lower part, where the unusual feature of a heavy pressure on the masonry called for especial vigilance. With the exception of Shaft 24, where a leak (not altogether unexpected on account of the unfinished condition of the work at that point), developed itself, the aqueduct appears to be in excellent condition, and, although the saturation of the ground below Shaft 19 must be expected to a certain extent, the present absence of visible signs of it after two weeks of service is a matter of congratulation."



HOUSE AT BROOKLINE, MASS.—ARTHUR LITTLE, ARCHITECT, BOSTON.

COST OF DIFFERENT METHODS OF POWER TRANSMISSION.

THE following comparisons of cost of transmission of power by various methods appeared in the *Revue Universelle des Mines:* (1) Comparative cost on 10 horse-power transmitted 1,093 yards: By cable, 1.77 per effective horse-power per hour; by electricity, 2.21; by hydraulics, 2.90; by compressed air, 2.98. (2) Comparative cost on 50 horse-power transmitted 1,093 yards: By cables, 1.35 per effective horse-power per hour; by hydraulics, 1.87; by electricity, 2.07; by compressed air, 2.29. (3) Comparative cost on 10 effective horse-power transmitted 5,465 yards: By electricity, 2.64 per effective horse-power per hour; by compressed air, 4.66; by cables, 4.69; by hydraulics, 5.29. (4) Comparative cost on 50 effective horse-power transmitted 5,465 yards: By electricity, 2.37 per effective horse power per hour; by cables, 2.65; by compressed air, 2.99; by hydraulics, 3.02. Steam was the prime mover used in each of the above instances, and it appears that for long distances electricity takes the lead in economy over all other systems. The figures are interesting and valuable as comparative measures of commercial efficiencies.

DISINFECTION OF EXCREMENTITIOUS SUBSTANCES.

An account of some experiments on the practical disinfection of excrementitious substances is given by Dr. S. von Gerlóczy in the *Deutsche Vierteljahrschrift für öffentliche Gesundheitspflege*, and is reproduced, in part, in the volume of foreign abstracts of the British Institution of Civil Engineers.

The experiments were carried out in the course of the past year at the Pesth Hygienic Institute, in order to test the real values of the various substances employed as disinfectants, concerning which much difference of opinion had been expressed. The author divided the matters to be disinfected and deodorized into five groups—viz.: (1) Night soil from cess pits; (2) liquids from sewers; (3) solid contents of street gulleys; (4) dry road scrapings; and (5), fresh excreta of patients suffering from acute diarrhœa and typhoid fever. The disinfectants used were: (1) corrosive sublimate; (2) iron sulphate; (3) zinc sulphate; (4) copper sulphate (for comparison); (5) crystallized carbolic acid; (6) raw carbolic acid (two descriptions of which are obtainable, that employed by the author, known as 50 to 60 per cent. solution, actually contained 18.7 per cent. of carbolic acid); (7) carbolized lime, commercially known as 5 per cent., but yielding on analysis 2.1875 grams of carbolic acid per 100 grams; (8) creolin, (9) *α*-oxynaphtoic acid. On the score of their extreme cheapness the author used also: (10) raw concentrated sulphuric acid; (11) freshly slaked lime; (12) boiling water; (13) hot and cold solutions of wood-ash lye (specific gravity of the lye 1.037, equivalent to 4 per cent. of carbonate of potash); (14) solution of common salt, containing 26.1 per cent. of salt. Specimens of the disinfected materials were withdrawn on a platinum needle, and introduced into warm fluid peptone-gelatin. The cultivation took place both at ordinary temperatures, and also at a temperature of from 35° to 37° Centigrade.

The specimens were examined at intervals of 24 hours, 48 hours, and three to four days after treatment.

Group I. *Night Soil.*—Samples for experiment were obtained from a night soil removal contractor; 100 grams were placed in a glass vessel, and treated with weighed quantities of each of the disinfectants enumerated, in various proportions. The results are set forth in detail, and they show that a practical disinfection of night soil is all but impossible, as even 2.5 per cent. of corrosive sublimate is insufficient to render it germ-free; this quantity would entail a cost of 150 gulden ($47.80) per cubic meter. Complete sterilization resulted from the use of a 4 per cent. solution of copper sulphate, and it would appear from this that with this material, one cubic meter of night soil could be disinfected at a cost of 12 gulden ($5). For the purpose of deodorization the use of raw carbolic acid may be regarded as successful.

Group II. *Sewage Water.*—Was treated with the foregoing disinfectants in a similar way, full details of the experiments being given. Here again the author draws attention to the extraordinary value of copper sulphate; a solution of 1 per mille sufficed to destroy all germs, and rendered the liquid clear and inodorous.

Group III. *Sludge from Gulleys.*—The series of experiments recorded shows the extreme difficulty of disinfecting thoroughly this substance. For deodorization, carbolized lime in moderate quantities sufficed, but the author recommends the use of raw carbolic acid diluted to 1 per mille.

Group IV. *Street Sweepings, etc.*—Owing to the last cholera outbreak in Pesth, the authorities ordered that carbolized lime should be freely used in the dwelling houses, and they caused it to be strewn along the roads, against walls, under doors, and over gulley holes. The author therefore carried out special experiments to test the value of this treatment, and to ascertain how far it might be possible to practically disinfect road sweepings. Treated with the foregoing disinfectants it became manifest that complete disinfection was out of the question. Even where thoroughly soaked with solutions of corrosive sublimate, copper sulphate, etc., the road dust was far from sterile; nor did experiments with respect to the strewing of carbolized lime yield satisfactory results. The advantages of this mode of disinfection are illusory.

Group V. *Disinfection of Excreta.*—In certain cases it becomes of the utmost importance to thoroughly and rapidly sterilize the dejections of patients. The excreta used for these experiments were in all cases diluted with three times their weight of water. All the various disinfectants were tried in different proportions, and the results of the experiments are recorded. The conclusions arrived at by the author are: That a strong solution of copper sulphate should be used, at least 1 gram of the disinfectant being added to 100 cubic centimeters of excreta; but still better results arise from the employment of thrice their weight of boiling lye (2 parts of water to 1 part of wood ashes). Milk of lime (1 part of slaked lime in 20 parts of water), used in the proportion of $\frac{1}{8}$ to $\frac{1}{10}$ of the weight of the excreta, likewise disinfects cheaply and well.

MAINS FOR HIGH PRESSURE ALTERNATING ELECTRIC CURRENTS.

In a paper under the above head by C. Jacquin, published recently in *La Lumière Electrique* and abstracted in the Excerpt Minutes of the Proceedings of the British Institution of Civil Engineers, the subject is treated from two points of view: first, as regards loss of current by leakage, and second, as regards loss of energy by induction.

It has been shown by Foederruther that the insulation resistance of a cable diminishes by 10 per cent. if the pressure be increased from 1 to 100 volts, and assuming this ratio to hold good for higher pressures, Mr. Jacquin finds that the insulation resistance of a 2,000-volt cable must be 20 times that of a 100-volt cable. The specification for the cables to be used in connection with the 2,400-volt alternating currents supplied from the Municipal Station at the "Halles," Paris, stated that the insulation shall be 1,000 megohms per kilometer, or about 624 megohms per mile.

The equivalent insulation of a 100-volt cable would, at this rate, be only 26 megohms per mile. Moreover, the insulation of the cable is further reduced by joints, and it was, in the case of the "Halles" installation, specified that the insulation of the cable after laying should not be reduced by more than 10 per cent. The insulation employed by some German and Austrian cable-works is jute impregnated with some resinous compound, and the insulation resistance immediately after manufacture is given as from 310 to 375 megohms per mile. These standards, the author thinks, cannot be maintained, since all fibrous substances are hygroscopic, and with the admission of moisture the insulation must be lowered. As a matter of fact, such cables after laying have never reached even 62 megohms per mile. The author gives the following formula for the insulation resistance of high-pressure cables:

$$M = \rho \frac{l}{E},$$

in which ρ is the total insulation resistance, l the total length in kilometers, and E the pressure in volts. The coefficient M is 400,000 ohms per volt per kilometer of the cables used at the "Halles" installation, and the author considers a cable to have become unsafe if M has decreased to 10,000 ohms per volt per kilometer.

The author next investigates the induction effect of alternating currents in cables. He shows that two simple unarmored cables, laid side by side, are likely to disturb neighboring telephone lines, which disturbance can be avoided by the employment of concentric cables. If single cables are individually provided with iron armor, or if two single cables are placed within the same iron tube, exterior disturbance is also avoided, but a certain loss of energy is incurred, consequent on the magnetization of the iron. The magnetic circuit, in the case of single armored cables, is completely closed, but in the case of two cables within the same iron pipe the lines of force flow partly through air and partly through iron, and the waste of energy is less. The author has made experiments to determine this waste of energy in a cable of 220 yards length, laid in the works of Mr. H. Ménier, at Grenoble. The cable was looped to bring its two ends close together, and these could be joined, by means of a special switch, with the terminals of a dynamo and those of an alternator. There were in circuit a rheostat, a wattmeter and a dynamometer. The experiments were made in the following manner: The switch was placed to the alternator, and the readings of the dynamometer and wattmeter were noted. The switch was next placed to the dynamo, and the rheostat adjusted, until the dynamometer indicated the same current as before. The wattmeter indicated now simply the loss by ohmic resistance, and this reading, deducted from the previous reading, gave the loss due to hysteresis and eddy currents in the previous experiment. Three cables were thus tested, the first having no metallic covering, the second having a lead sheath, and the third being covered by lead and armored with iron wires. The copper conductor of all the cable had a sectional area of 0.0465 square inch, insulated by pure rubber. The frequency of the alternating current was 50 cycles per second. The current was 18 amperes. In the first cable no energy was lost beyond that due to ohmic resistance. With the lead cable two experiments were made. In the first the cable rested on the ground, and the two ends of the lead tube were not otherwise connected; whilst in the second they were short-circuited by a copper wire. The losses were, respectively, 1 and 2 per cent. of the loss due to ohmic resistance. With the armored cable three experiments were made—namely, (*a*), the ends of lead and iron covering insulated; (*b*), lead covering insulated, and iron covering connected; and, (*c*), lead and iron covering connected. The losses in these cases were, respectively, 18, 27.4, and 34.5 per cent. of the loss due to ohmic resistance. With a frequency of 25, all the losses were about 60 per cent. of their former value. The experiments were not repeated with a higher frequency than 50, but the author estimates that, with a frequency of 100, the loss in the most unfavorable case, (*c*), would not exceed 50 per cent. of that due to ohmic resistance, or, say 2.5 per cent. of the total energy flowing through the cable.

DRY AIR REFRIGERATING APPARATUS WITHOUT MACHINERY.

Under the above head London *Engineering* describes what is known as Hill's system of dry air refrigeration, recently shown at the Royal Military Exhibition at Chelsea, England.

The distinctive feature is that no machinery is in use, the cold air being produced from the distillation of ammonia gas, a principle which is not by any means new. The apparatus consists of steam generator, ammonia boiler, separator, and condenser for producing cold, and a refrigerator or cold chamber. This chamber is constructed in most cases of a double casing of wood, lined with charcoal as a non-conductor, and the roof is formed by a tank containing a bath of chloride of calcium liquor in sufficient quantity to store up the cold as produced. The solution of ammonia in the boiler is heated by steam from any boiler, or from a specially constructed slow combustion stove, with a spiral coil giving large heating surface. Alongside it is placed a water separator for drying the steam, which passes to a boiler three-fourths filled with a solution of ammonia. To this the steam entering by several pipes imparts heat, driving the ammonia into the form of gas. Above the boiler is placed a separator for taking off water carried forward in the distillation of the ammoniacal gas. The water thus separated passes by gravitation to the boiler. Alongside it is a corresponding cylindrical vessel into which the dried ammoniacal gas passes, and there it is condensed by its own accumulation of pressure and the latent heat carried off by the circulation of cooling water. This liquid anhydrous ammonia flows into the refrigerators suspended in the tank forming the roof of the cooling chamber. The pressure is then rapidly reduced by opening a communication with a separate chamber, and the sudden evaporation of the liquid anhydrous ammonia takes place at the expense of the sensible heat in the cold storage bath in the tank, which therefore becomes very cold and draws heat from the chamber in which the meat is stored. The bottom of the tank is corrugated, which gives a large increase in the cooling area, and to the lower angles of the corrugation gutters are suspended carrying off the water, so that the atmosphere is dried as well as cooled.

PRESERVING ROPES.

It has been suggested in a French paper that in order to insure greater strength, and consequently more safety in ropes used for scaffolding purposes, particularly in localities where the atmosphere is destructive of hemp fibre, such ropes should be dipped, when dry, into a bath containing 20 grains of sulphate of copper per liter of water, and kept in soak in this solution some four days, afterward being dried; the ropes will thus have absorbed a certain quantity of sulphate of copper, which will preserve them for some time both from the attacks of animal parasites and from rot. The copper salt may be fixed in the fibres by a coating of tar or by soapy water, and in order to do this it may be passed through a bath of boiled tar, hot, drawing it through a thimble to press back the excess of tar, and suspending it afterward on a staging to dry and harden. In a second method the rope is soaked in a solution of 100 grammes of soap per liter of water.

One man was killed and another was hurt seriously by the falling of part of a big chute at the Western Union Building, New York, on July 30. The chute was erected soon after the recent fire, to enable workmen to pass down rubbish from the upper stories to the street. It extended up as far as the eighth story, and its lower end hung over the gutter of the street. Many tons of rubbish were thrown down the chute after it was built, but it became clogged on the day of the accident, because the stuff had not been removed promptly from the lower end. The greatly increased strain thus brought to bear on the structure caused its lower half to give way, carrying two workmen with it.

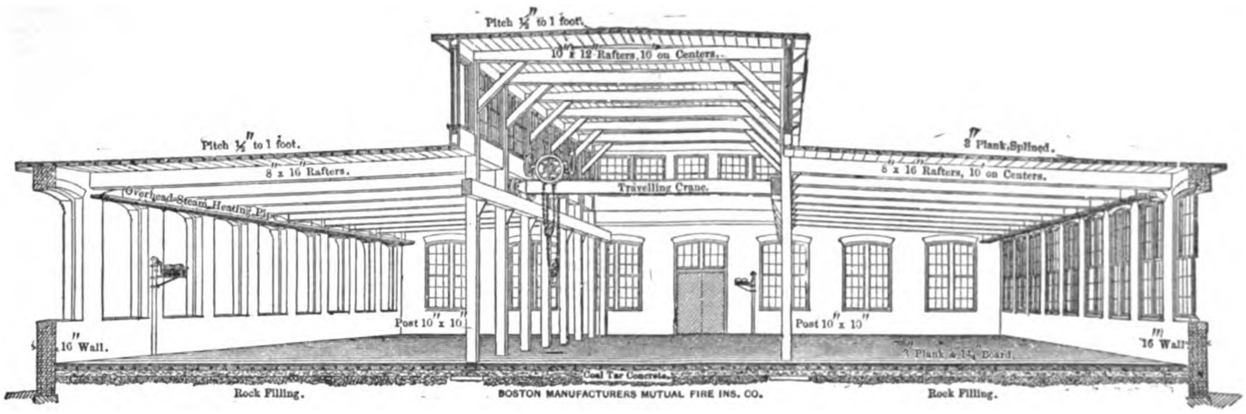


FIG. I.—MACHINE SHOP, SECTION.

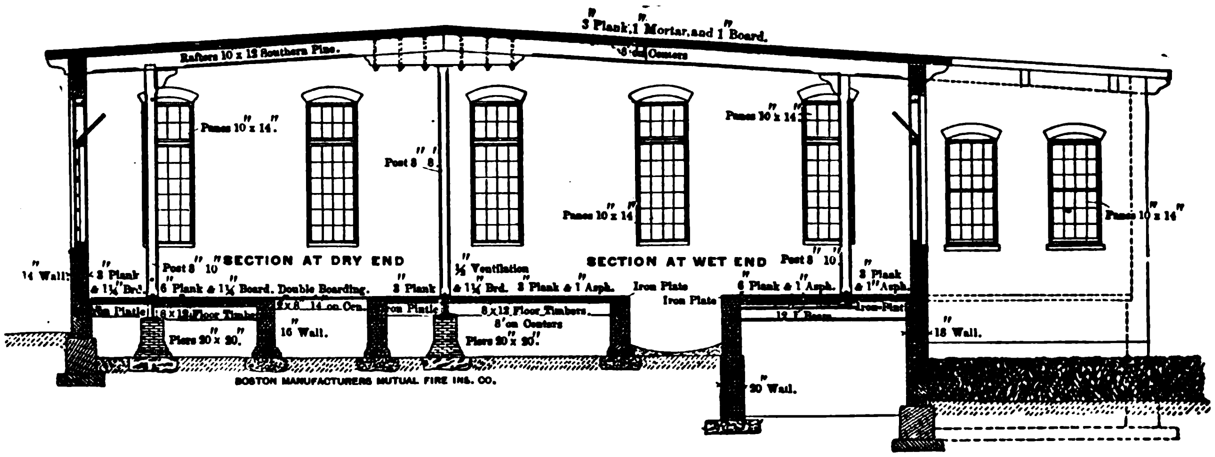

FIG. 2.—PAPER MILL, SECTION OF MACHINE ROOM.

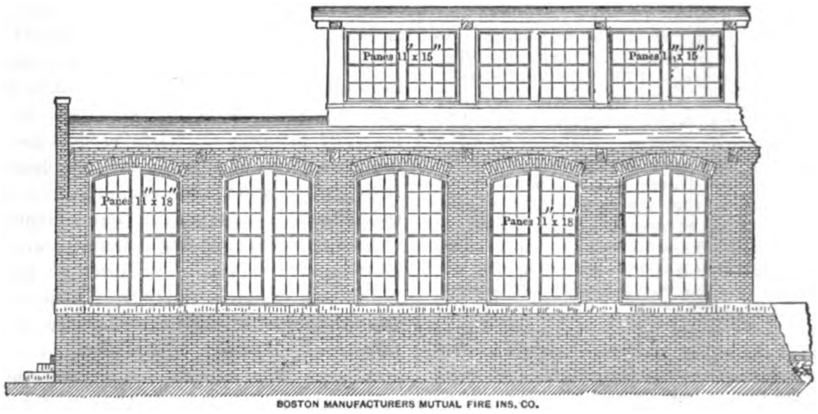

FIG. 3.—MACHINE SHOP, ELEVATION.

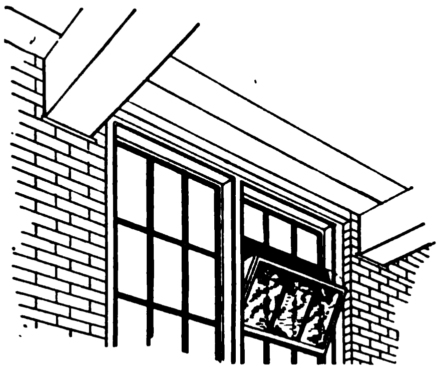

FIG. 4—WINDOW VENTILATOR.

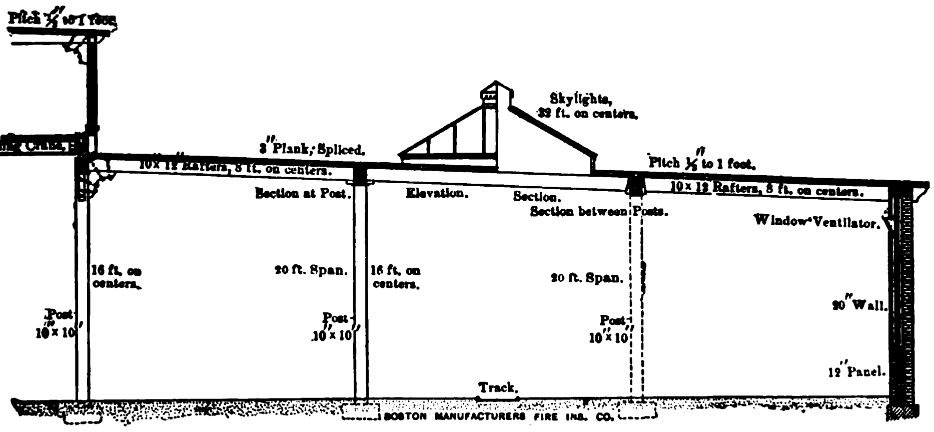

FIG. 5.—FOUNDRY, SECTION.

EXAMPLES OF ONE-STORY SLOW BURNING CONSTRUCTION.

THE accompanying illustrations represent examples of one-story, slow burning construction recommended by C. J. H. Woodbury, for the Boston Manufacturers Mutual Fire Insurance Company, to whom we are indebted for the engravings and particulars. The designs embrace improvements which have been developed by experience in the construction and use of one-story factory buildings up to the present time.

For establishments on cheap, level land, especially where the stock is heavy, one-story buildings have proved to be more economical in cost of floor area, supervision, moving stock in process of manufacture, and repairs to machinery—many kinds of which can be run at greater speeds than when in high buildings. Such buildings are readily warmed and ventilated, and heavy plank roofs are free from condensation in cold weather; the large window area reduces the hours of artificial illumination.

Forced circulation of heated air is a very desirable method of heating a mill, being economical as to maintenance and repairs, and thoroughly under control. Overhead steam pipes are very satisfactory, if used in the ratio of 1 foot of 1¼-inch pipe to 70 cubic feet of air.

It is convenient in machine shops to provide rails extending the length of the building under the roof timbers for the purpose of clamping counter-shafts to these rails as may be desired.

Floors.—Floors over an air space or on cement are subject to dry rot. Asphalt or coal-tar concrete is softened by oil, and the dust will wear machinery unless covered by flooring. Floors made by laying sleepers on 6 inches of pebbles, tarred when hot, then 2 inches tarred sand flush to top of sleepers and covered by double flooring, have remained sound since 1865; but double flooring at right angles can be laid on the concrete without the use of sleepers, and nailed together. It is usually preferable to secure nailing strips to stakes 4 feet apart each way and driven to grade, concrete flush to top of strips, and lay single 1½-inch flooring.

Walls.—Piers reach to roof timbers, and light walls to window-sills are finished with slope on inside. In some instances it is preferable to build brickwork up to window-sills, and support the roof by square posts filling the spaces between the windows, and which are secured to the beams by timber knees or iron brackets Large windows are placed high, and the sashes separated by a mullion. Lower sashes should be stationary and glazed with rough glass, with transom sash or window ventilators above. If the light is too strong apply to glass white zinc and turpentine.

The swinging sashes in monitor can be moved in groups by bell cranks from a shaft turned by an endless screw. The connection should not be rigid, but flexible steel links or springs should be introduced to provide for the sashes being out of line, and also to close them with an amount of yielding pressure sufficient to prevent any jarring.

Columns.—Wooden mill columns, Southern pine or oak, safely sustain loads of 600 pounds per square inch;

a square column is stronger than a round one of the same diameter. They should have a 1½-inch core bored from end to end, and two half-inch holes through the column near to each end.

The columns should be securely held at each end, the base resting on iron plates projecting above the floor level, and the caps at the top bolted to the roof beams.

Roofs.—Double or solid timbers of Southern pine support the roof plank, and the ends pass through the wall, and are finished as brackets to the cornice. The beams are anchored to plates in the walls by means of tongues which project into grooves across the lower side of the beams. Beams should not be painted or varnished until thoroughly seasoned.

The roof planks should be two bays in length, breaking joints every three feet. There is no need of gutters, but a concrete walk, sloping toward drains, will take the water from the roof. Do not drive nails upward into the roof plank, as moisture will condense and drop from the heads.

The form of paper machine room shown in Fig. 2, with thick, solid roof, has proved to be very successful in practical operation, being comfortable and free from vapor, and easily ventilated.

The ventilator shown in Fig. 4 is made by removing a row of lights from a window and securing to the inside an inclined sash in a suitable frame, and with hinged cover having an overhanging edge. It does not interfere with the light, or motion of the sash, can be opened or closed at will, and, the air being directed against the ceiling, does not produce draughts.

The foundry roof (Fig. 5) has no lodging place for dust if a sloping cover is placed on the small portion of beams under the skylights. The stringing beams hold the alternate roof beams by iron stirrups, and should be 10 by 15 inches. The roof plank should be slightly raised at the left of the skylights.

The illustrations are on a scale of 14 feet to the inch.

DESTRUCTION OF LARGE MASSES OF IRON AND STEEL BY BLASTING.*

THE author classes these under three heads—viz.: (1) Bodies which can be broken, or rather blown to pieces, by charges of dynamite laid loosely on or against them. (2) Hollow bodies, where the blasting charge can be placed as in a bore-hole, or whose capacity is sufficiently large to admit of their being filled with water, into which the dynamite charge can be placed. (3) Huge masses of steel or iron which must be bored into as if they were rock and then blasted.

Under the first head is included mainly the destruction of iron railway bridges in time of war, and which the civil engineer therefore seldom has an opportunity to deal with. The author, however, quotes the iron bridge (on the Leipzig-Dresden line of railway) over the Elbe at Riesa which, destroyed by a flood in 1870, fell into the river below, completely blocking the bed, and had to be blasted out.

Under the second head are comprised large guns, press-cylinders, boilers, etc.; and, under the third head, rolled steel and iron plates, and rails, cofferdam piles, blast-furnaces, etc.

The formula adopted by the Corps of Military Engineers, for bodies classified under the first head, is $L = 0.0063ba^2$,

where L = dynamite charge in kilograms.
b = breadth of body in centimeters.
d = thickness " "

and this formula applies to wrought-iron structures solid or riveted, provided the rivets are more than 16 centimeters apart; but wrought-iron plates with rivets less than 16 centimeters apart, and all cast-iron plates require only half the charge given by the formula; cast-steel plates, however, require double this charge. Examples are given of the application of the formula to the case of an iron chain-link, and two girders of different section. Under No. 2 head it is stated that the charge for guns, or other similar bodies filled with water, would be 0.1 kilogram of dynamite per centimeter of diameter; for example, for a gun 16 centimeters in diameter, the dynamite charge would be 1.6 kilogram. The following particulars are given of the blasting of a 21-centimeter breech-loading bronze gun. The tube was 4.425 meters (14.5 feet) in length.

Diameter of bore in the rifled part = 20.9 centimeter (8.25 inches).

Thickness of metal at the breech = 31.3 centimeter (12 inches).

The total weight was 14,169 kilograms (31,171 pounds), and the breech chamber was lined with a copper tube 94.8 centimeters (37.323 inches) long, and 6.6 millimeters (0.025 inch) thick.

The committee which conducted the experiment filled the gun with water, and then exploded a charge of 6 kilograms (13.2 pounds) of dynamite in it. This did little damage, so the water was poured out, and a second charge of 36 kilograms exploded; this only bulged and cracked the tube but did not burst it. A third charge of 94.5 kilograms of dynamite shattered the gun into thirty-four large and forty smaller pieces, of which the largest weighed 1,850 kilograms, and four other pieces 1,500 kilograms each. The committee's referee gave it as his opinion that the charge of 94.5 kilograms was the proper charge to have used at first, the gun having been previously filled with water. Other examples are given of the success of the author's experiments in the Archduke Albrecht's works at Trzynietz, in destroying with dynamite a large press cylinder and two boilers, the charge in each case being less than half that given by the formula above for guns, the reduction being due to the trifling thickness of the metal in comparison with the diameters of the cylinder and boiler. Under the third head, the author confirms the opinion of Engineer Trauzel, Director General of the Nobel Dynamite Works—viz.: That bore-holes from 21 to 30 millimeters in diameter and repeated small charges are the only rational methods of blasting very large masses of iron or steel; and he has found that 1,000 kilograms of these metals can be blasted into pieces sufficiently small for recasting at a cost of about 2½ florins.

The paper is illustrated by diagrams and sections of the various bodies experimented on.

THE PURIFICATION OF SEWAGE.

IN discussing the sewage purification problem, the London *Engineer* of recent date says:

"We are justified in saying that the problem remains to a very large extent as insoluble as ever. It is possible to purify sewage to a certain extent, but only at a very serious outlay; and a gallon of really first-class effluent may easily be made to cost as much as indifferent beer. It is very difficult to decide what process of several contending for patronage gives the best result for a given outlay; and all over the country local boards and town councils are trying experiments, and spending money with more or less inconclusive results. The difficulty of purifying sewage augments with its dilution; the more nearly pure it is to begin with, the more difficult it is to make it purer. Thus, if every gallon of sewage contained a pound of impurity, there would be little trouble in getting out half a pound; but when the impurities are measured by grains instead of pounds, it becomes a difficult task to extract the last dregs of objectionable matter.

"Among several systems claiming attention, there are two which, at all events, promise a great deal. The first of these is the electrical process. Plates of wrought iron are placed in tanks containing sewage, and a current of electricity is made to flow from plate to plate through the sewage. The result is that a very tolerable effluent is obtained. The theory of the process is simple enough. In the first place, the iron plates corrode, and the oxide of iron acts as a purifier in a way not, perhaps, fully understood, although more than one plausible explanation has been advanced. But this action of the iron is only secondary · the efficiency of the process is mainly due to the decomposition of the sodium chloride—common salt—which all town sewage contains to the extent of 50 or 60 grains in the gallon. This salt goes away from our dinner tables. All but a small portion of the contents of our salt-cellars ultimately finds its way into the sewers. The water in which salt provisions are boiled supplies a considerable quantity; the spent brine from the butchers is discharged into the sewers. The wonder is, not that sewage contains so much salt, but that it contains so little. The electric current decomposes the salt. The chlorine is set free, and acts as a disinfectant. It decomposes water, setting free oxygen, which, in its nascent condition, readily enters into new combinations. Chlorine combines with hydrogen present in putrefying matters, and forms hydrochloric acid. It appears that if salt were not present in sewage, the electrical process would have little or no value; and it is not improbable that the addition of sea water to sewage might be found of considerable utility.

"The second process to which we have referred consists in filtering the sewage through a bed of the material known as polarite. A certain amount of mystery is maintained concerning this thing. It appears, however, to be nothing more or less than an oxide of iron found in a spongy condition. Iron oxide has long been celebrated for its purifying action on water, and polarite supplies the oxide in a form mechanically perfect in its adaptability to the intended purpose. The surface exposed in each fragment of polarite is comparatively enormous. There still exists, however, incredulous individuals who assert that polarite does not accomplish as much with sewage as the world has been led to believe. On this point we express no opinion, because we do not think enough is yet known with certainty to permit us to speak positively one way or the other. The representatives of polarite, however, do not, it must be said, trust to it alone, because they treat the sewage as a preliminary with a dose of what they term 'ferrozone,' which seems to be an iron sulphate. Concerning the cost of the process we are unable to say anything. It is urged by the disbelievers in the polarite that just as good an effluent may be got with sand by itself, but they adduce no proof of this. There seems to be no doubt but that with either electricity or polarite an effluent can be obtained which is sufficiently good.

"The unsatisfactory condition of the purification of sewage problem seems to be due, in large measure, to the Protean form it assumes. Nothing, for example, is easier than to send specimens of sewage and effluent to the chemist for analysis; but the examination of a dozen, or even ten times as many specimens may give inconclusive results. Not only is it next to impossible, in many cases, to find two samples of sewage alike on the same day, but from house to house, almost, changes take place in its character. Thus, for example, the sewage from the West End of London is quite different from that discharged by the East End. A process therefore which might answer admirably in the case of a large agricultural town, might be unsuitable to a place where manufacturing processes were carried on. Of course, certain impurities are common to all sewage; but the quantity varies with the district, with the weather, and the water supply. Curiously enough it is the amplitude of the water supply in great towns that has told so heavily against the process of purification. To render a few thousand gallons of, so to speak, concentrated sewage fairly pure is a comparatively simple and inexpensive matter; the treatment of a deluge of weak sewage is quite another thing. The extent of land necessary is enormously increased if sewage farming be attempted, and if chemical treatment is adopted the outlay on tanks, etc., is very greatly augmented. The variations in the quality of sewage render experiments inconclusive, and this leads to delay. Corporations and town councils naturally desire to get the best possible value for an outlay which must, in any case, be high; but, unfortunately, the experience of any one town is seldom conclusive as regards the fitness of a process or a system to the case of another town. Thus, we have experiment after experiment, and meanwhile the effluent is impure."

UTILIZING WASTE AS BUILDING MATERIAL.

IN a paper on utilizing waste products, published in the *Wochenschrift des österreichischen Ingenieur und Architekten Vereins*, and abstracted in Excerpts of Proceedings of the Institution of Civil Engineers, it is pointed out that a good and useful building material may be produced by roasting at a temperature of 302° Fahr. the rubbish obtained from old buildings; that by such process so much water is driven out of the material as to reduce the volume from 20 to 40 per cent., and hence the employment of such a perfectly dry material in a building will prevent the settlements so often observed, resulting from the drying of the material within the walls of the building itself. A further advantage is a sanitary one, for while the original waste product may contain within itself the germs of disease, these are destroyed by the intense heat to which they are subjected in roasting, and the material is therefore completely disinfected.

Another useful building material is manufactured from blast-furnace refuse in the form of bricks and paving slabs, and this has established a new industry in the smelting houses on the Schwechat near Vienna, where the furnace slag is broken up and mixed with hydraulic lime and then molded under steam pressure into bricks. The value of the product consists in the formation of silicate of lime from the combination of the silica in the slag with the lime, resulting in a hard material which increases in hardness on exposure. The brick in this condition is of a uniformly grayish white color of rather coarse grain and very sharp edges, and possesses in a high degree the two valuable properties of permeability and porosity, and thus constitutes an essentially healthy building material The durability of the material, too, has been tested by a 15 years' exposure in some cases, and no signs of wear or weathering have been noticed; in short, the results of its employment have been so favorable that it has been recommended by the Board of Works for general purposes, and to be used with a mortar made from slag, sand and hydraulic lime.

Paving slabs are now made according to a patent process by mixing furnace slag with Portland cement and other constituents, which produce rapid hardening and great strength, and such pavements are now laid down for special purposes in London, Paris and Vienna.

THE determination of the speed at which the air is changed in inclosed spaces is a problem which has frequently to be solved. A plan of measuring it proposed by Pettenkofer, depends upon estimating the decrease in carbonic acid which takes place after a given time in an atmosphere artificially charged with this gas, by which means the amount of fresh external air which has become mixed with that under examination can be calculated. Other methods which depend upon the thermometer and the anemometer may be used to check that of Pettenkofer.

IN the irrigation canals of India the water flows with a velocity of 1¾ feet to 2 feet per second, in light sandy soil. In more stable soils a velocity of from 2½ feet up to 4 feet is adopted.

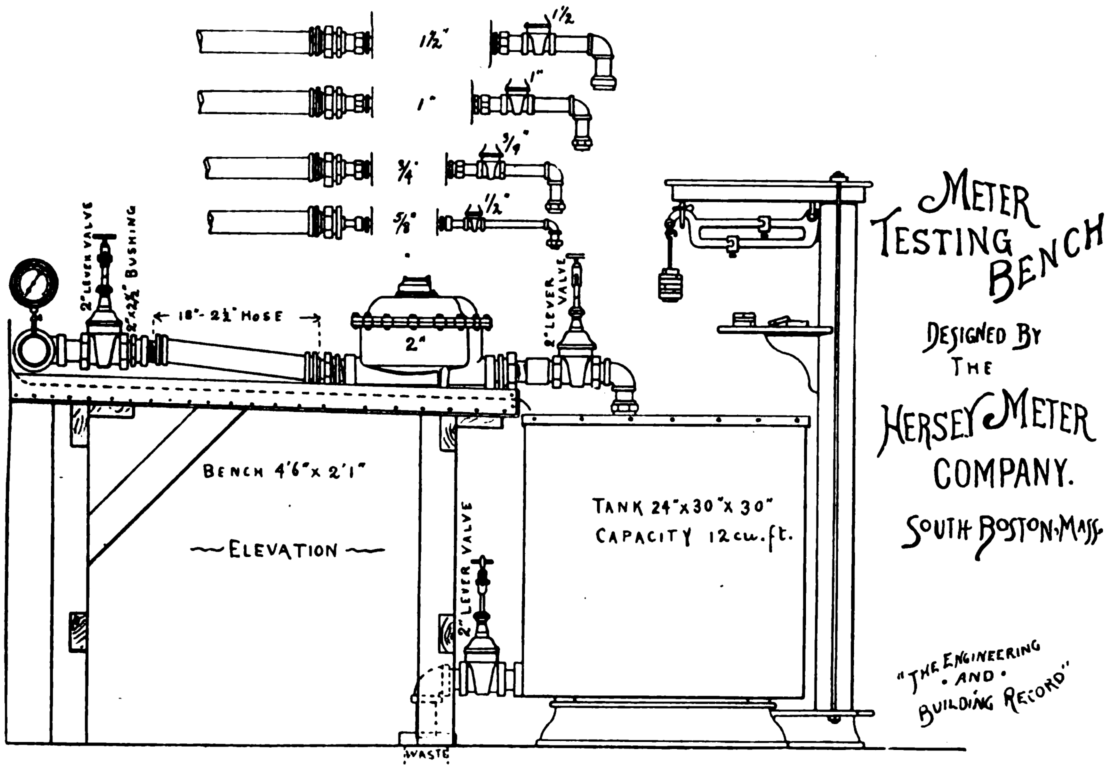
NEW ENGLAND WATER-WORKS ASSOCIATION SKETCHES.

No. XVI.

(Continued from page 121)

WATER METER TESTING BENCH.

THE meter testing bench shown in the annexed illustration was designed by the Hersey Meter Company, of South Boston, Mass., and formed one of the series of subjects of which sketches were presented at the meeting of the New England Water-works Association, at Portland, Me., a few weeks ago.



It will be noted that the arrangement is designed for testing meters of various sizes, connections being shown for meters ranging from ⅝-inch to 1½-inch, with a 2-inch meter in position. The method of testing will at once suggest itself and calls for no further explanation. The bench is covered with No. 18 galvanized sheet iron. The tank has a capacity of 12 cubic feet.

REGARDING CHARGES FOR WATER.*

REPORT OF COMMITTEE ON WATER-WORKS.

IN reply to the following question: Should applicants for extensions of water mains be obliged to guarantee a certain percentage where the property is, or has been, paying water taxes? If so, why? And what is a reasonable percentage?

Answer: Yes. A system of water-works should be conducted on purely business principles. Where the income from water is not sufficient to pay interest on the cost of the works, together with the cost of maintenance, no extension should be made until such a sum is guaranteed, in addition to the regular rates, as will cover the interest on the cost of such extension.

There is not the urgent need for water in the suburban part of a city that there is in the built up portion, and to demand that it be piped on the same scale would ruin any private enterprise.

W. H. RICHARDS,
A. R. WADSWORTH,
HENRY W. AYRES.

Mr. Whitlock: I wish to give you a case—not exactly a supposed case—but is a standing matter of fact with us in Waterbury. We have a system of water-works, owned and run by the city, and there is a clause in the charter which prohibits it supplying any parties outside of the city limits (except where that supply has been given in return for value received from these parties in some manner, such as the right of way through their property). In two cases I think of parties who are supplied under that clause. Otherwise all parties within the city may obtain water by complying with a certain amount of red tape. Now, here is the case:

There is a party, who, owing to certain combinations or circumstances, has been unable to get water. He has lived too great a distance from the supply to make it advisable to get to him until say this year. This year, in the course of extension, the pipe has come within such distance of his house or property that he can, with propriety, ask for water from the city. Now, he has paid water taxes; in other words, he has paid a certain proportion of his city taxes, which has been diverted and used for water-works, pure and simple, and nothing else. Now, is it proper to require him to guarantee sufficient cost to pay the interest and expense of laying 300 feet of pipe?

Mr. Ayres: Yes, it is.

Mr. Whitlock: When he has already paid for 10, 12, or 15 years?

Mr. Ayres: Yes, for he has been paying all this time, as well as his interest toward this water, also for electric lights and police protection.

Mr. Whitlock: He has already had the benefit of the lights, the benefit of the sewers, and the benefit of the police.

Mr. Ayres: And the benefit of the water.

Mr. Whitlock: In what way?

Mr. Ayres: Every way, except for his own direct benefit; the city has been benefited in sprinkling the streets and in fire protection, and he is interested in it, but he has been placed in an unfortunate position, that is all.

Mr. Whitlock: The circumstances rather had the best of him, and your idea is to keep him in the hole.

Mr. Ayres: My idea is to give him the water as soon as you can afford to.

Mr. Whitlock: Does that necessarily imply that he should guarantee he will pay enough to cover the cost.

Mr. Ayres: Yes, I claim that it does; that somebody now is paying for this water that the town of Waterbury is furnishing its water consumers. Now, then, this man asks for water, and if you put water into his place, why somebody has to pay for that pipe you run out. You may get one or two parties additional which will help him out, but because he lives a few feet inside the outskirts, where it costs more to supply him than any amount you can get back, if he wants the water he must pay for it.

Mr. Whitlock: At the same rate as others?

Mr. Ayres: By no means at all. He must pay so that the company will not be the loser, financially, by his taking the water. Don't make any difference whether it is a private company or whether it is a corporation.

Mr. Whitlock: For instance I am at the end of a street 500 feet long; I apply for water on it; I am the last man on the street; my application is granted, and for perhaps six months I am the only man who takes water on it. Is it not a fact that almost as soon as that case exists, it is rectified by other people applying for water and taking it?

Mr. Ayres: Well, when that happens you are free from your responsibility and guarantee.

Mr. Whitlock: How long should you make that guarantee last?

Mr. Ayres: Until there are enough water takers on your additional pipe to pay the interest on the outlay.

Mr. Chandler: Are you not given the benefit of it?

Mr. Ayres: The taxes will give it back to him.

Mr. Chandler: You make him guarantee for the first year the expenses, while you are making money?

Mr. Ayres: No, he is getting the benefit of it. The money is put back in the town sinking fund or something else. It is just exactly on the same principle as where we trade at a grocery store where a number of people don't pay their bills. We folks who do pay our bills have to pay their share too, and that's all there is to it.

Mr. Jarvis: You are pretty solid on the financial question, ain't you?

Mr. Whitlock: It has never seemed fair to me, for a man who is placed in the position I have just described, to be called upon to guarantee a revenue from a pipe in his street when, as in the case in Waterbury, and in many other cases, the water-works are not only paying, but are turning into the public treasury more money than they spend. In such a case as that it doesn't seem to me fair to require a man on the outskirts to guarantee anything of that sort.

Mr. Ayres: Why can't he just as well have an electric light in front of his house, and keep a policeman at the front door, as to take water he didn't pay for?

Mr. Whitlock: This man does pay, and has been paying for ten years.

Mr. Ayres: He pays for watering the streets down town so that the dust shan't blow in his eyes.

Mr. Whitlock: You may be right, but it don't look so to me.

Mr. Chandler: Because all other things run wrong, the water must be run so, too?

Mr. Ayres: You might just as well say that—well, I won't say it.

Mr. Jarvis: What is it, a hardware bill, this time?

Mr. Brinsmade: Should the same rules govern city water as govern a private corporation?

Mr. Ayres: I think just the same basis.

Mr. Brinsmade: You shouldn't expect a private corporation to put pipes out to a man unless he guarantees the interest on the outlay?

Mr. Bunce: That is not the question.

Mr. Brinsmade: The question is, supposing that this man is paying for water in taxes.

Mr. Whitlock: In a private corporation you have got into a different case entirely. A private corporation levies no taxes for water until the water is supplied. They may enforce restrictions, as they not only oblige him to guarantee a sufficient revenue to pay expenses of laying the pipe down there and maintaining it, but they oblige him to lay the pipe himself. That is a case I know of myself.

Mr. Brinsmade: You dont't think both ought to be on the same basis. You don't agree with Brother Ayres?

Mr. Whitlock: No, sir; I don't on that ground, because a man that lives in the city and is supplied by a public water company pays from the moment he takes up his residence in the city and owns property in it; he pays a certain proportion of the running expenses, and gets no direct benefits.

Mr. Ayres: Suppose that the water company is making money enough and assess no taxes?

Mr. Weld: No such case happens.

Mr. Ayres: In our own city of Hartford there has been no tax levied for water-work purposes for years and years.

Mr. Weld: No tax except the water bills?

Mr. Ayres: No tax except the revenue derived from water rents.

Mr. Bunce: Indirectly there is, because the city has been paying interest on a large amount of borrowed money all the time.

Mr. Ayres: The city, no! The water company has been paying their own interest on it.

Mr. Bunce: How long?

Mr. Ayres: It must be ten years. The last I knew about it one-quarter cent tax was paid to help it out.

Mr. Bunce: Indirectly, the city is still paying that, from the fact that if there was no interest on that bonded debt, the water rates, which is the water tax to users, could be diminished. Although the water would and is nominally paying its own interest, it is paid, of course, by the contributions of the citizens of Hartford, who are using the water.

Mr. Weld: The Water Board doesn't furnish water to the city free, or to any of its buildings free, but every man who lives in the city has to pay some certain taxes for the water that is used in the city buildings and for water used in the hydrants, so, as I said before, the case never happens when a man doesn't pay some water tax.

Mr. Ayres: You are not obliged to pay that tax?

Mr. Weld: No, but he has to pay something towards the cost.

Mr. Bunce: He can't escape, because the fact is the city is paying it.

Mr. Weld: He has to pay something into the treasury to pay for water in the hydrants, in the city buildings, etc.

Mr. Ayres: The hydrant tax would be a very small matter.

Mr. Weld: And this man who lives on the outskirts, he has to pay some water tax without getting any benefit.

Mr. Ayres: He is deriving the same benefit that he derives from having his house built up in proper shape. Same as you would if you lived in a school district, because it educates the people around you.

Mr. Whitlock: I would like to ask if any appropriation is made by the city of Hartford for the water department.

Mr. Bunce: The tax, I believe, is derived from the water rates, which are more than the expenses of running the department require. In other words, those taxes or water rates are made high enough so that each year the interest of the bonded debt, and a portion of the bonds are extinguished. The bonded debt, and thereby its interest, being wiped out, of course the water rates may be lowered to the same extent as the expense of running the department.

Mr. Loomis: It seems to me that the water rent business is explained in this shape: Now, for instance, a number of years ago I bought a place; no water in it, and I had to run a surface pipe from the main pipe to connect one or two buildings. In the course of time, when other parties came in and built, they tapped our pipes and drew the water away from us so that we were left without any pressure, although we had paid the expenses of laying our private pipe. In the course of time the city laid pipes. Now, in regard to water rates; the parties that own real estate have to see that the water rate is paid. The bondholders and those parties who own insurance stock, I don't know as they pay taxes, so, it really comes on the real estate holders to pay the water rates.

---

* From Transactions of the Connecticut Association of Civil Engineers and Surveyors, February, 1890.

Mr. Chandler: The privileges Mr. Ayres speaks of enjoying do not seem to be any reason why people who chance to get water a little further off from the center than others ought to pay anything additional. They have received these common benefits, so has every one else in equal proportion, and so it is policy to extend the water main to every citizen as soon as convenient. A man should not expect to get water until the main is somewhere near him, but when they do get sufficiently near so that it is convenient, and he has been paying the same tax, it doesn't seem just that he ought to pay any more for his water when he finally does get it, on account of having waited for it so long.

Mr. Wadsworth: It seems to me that this simply illustrates the point that a person residing in the corporate limits where there is a tax for public benefits, and who is so unfortunate as to be so far out that he cannot take advantage of the privileges he pays for, must simply wait the development and progress of the system until it reaches him This is a very common thing. In putting water-works into the towns in this State they charter a company and secure the right to tax all individuals within a certain district, perhaps in the whole town, and they tax every proprietor in the town, and he pays his proportion of the water rates, and has no advantage from it whatever. There has been considerable discussion of this subject during the last year, but I see in spite of it the people with no interest in the water-works are governed by the others, who are in the majority; those interested being leading citizens, willing to pay the tax, and make all others pay. The others receive no benefit whatever in any way, shape or manner. They simply pay taxes without receiving any public benefits that come from the use of the system pipes in the village. And now comes in this man who lives so far out beyond the system of water-works; he must simply pay until his hour comes, and wait until the water pipes come to him, unless he wishes to pay for pipe of sufficient size to furnish water for his place, or compromises with the city in some way by which he can secure that benefit for which he has been taxed this term of years, and I reply "Yes" to the question were it so spoken to me. There is no substantial corporation of intelligence, that I know of, that wouldn't lay pipes to connect with his place as soon as he advanced the funds to do it. I had a case in my system where there was a greenhouse that wished water; said they wished to lay pipes along in front of the place. About half the distance we had no takers of water, and it would cost more than the first year's rents, but there were other houses in that direction who would take water in time. Perhaps between the individual and the city there might be a compromise and each one pay half or a certain proportion, so that this man could actually receive the benefits for which he has been paying taxes.

Mr. Whitlock: I think that Mr. Wadsworth agrees with me, and will say that my method for supplying customers would be about equitable for all. It is this: A customer comes in that is far off, no large street main near him to supply him, which makes it exceedingly expensive. He comes in and says he must have water and is willing to pay for it, to which the water-works say, "If you want the water, you lay your pipe, and when we get so it is required by the city, we will pay you the cost of laying that pipe and take it up; take it off your hands." Would you consider that an equitable arrangement?

Mr. Wadsworth: It would depend upon the size of the pipe.

Mr. Whitlock: He lays one sufficient to supply him and the section between him and the existing main. This is the method I have seen adopted in one or two cases.

Mr. Ayres: Well, if he is willing, that is his lookout.

Mr. Bunce: That would be great deal more of a hardship than under the present arrangement. Mr. Ayres, when you lay a pipe here you pay the expenses, but ask the applicant to guarantee a certain income upon the expense of laying that pipe?

Mr. Ayres: Certainly; then you can lay pipes that fit into your system. You don't let a man put in different sizes of pipes here and there.

Mr. Kunce: The only difference, Mr. Whitlock, in the case you speak of would be this: That in the case where the man guarantees a certain percentage on the cost, he eventually loses that, and in your case he puts out a very much larger expenditure of money at first and some time gets it back. All he loses is the interest on the money in the meantime.

Mr. Whitlock: Yes, and the general result is that he gets it back in the course of two years.

THE Mannesmann process of tube making is to be carried out on a large scale in England. The London Steel Company's works have been bought for the purpose by a syndicate headed by Siemens and Mannesmann.

PLANS for new water-works, estimated to cost $235,000 have been ordered by the Dundee, Scotland, Water Commissioners.

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

No. XCVIII.

(Continued from page 105.)

RAISING AND MOVING A BRICK FURNACE.

THE Worcester Steel Works, of Worcester, Mass., some years ago built a large 12-ton steel furnace with brick walls braced by the iron rails R R, etc. Figs. 1, 2, 3 and 4, and tie rods B B, etc., having a total estimated weight of from 200 to 250 tons.

In building the foundations excavations were made to what was supposed to be the natural gravel bed and the structure erected thereon. After a time, however, it was noticed that the furnace was settling, especially on one corner, and this settling became so bad that it was decided to rebuild the foundation and at the same time to move the furnace 3½ feet horizontally. It had been ascertained by soundings that what was supposed to be a gravel bed was in reality a gravel filling on top of a lot of cinder. From the heat of the furnace and gas flues this cinder had caught fire and was gradually burning out, causing the settling.

Fig. 3 is a plan of the furnace from X X, Figs. 1, 2 and 4, and shows the brickwork in section and everything else in plan.

Figs. 1 and 2 are elevations from Z Z and Y Y, Fig. 3, respectively, and show the timbering and jack-screws for raising the furnace.

Fig. 4 is an elevation from Z Z, Fig. 3, and shows the timbering, screws and rollers for moving the furnace horizontally.

The first thing was to get a solid bearing on which to support the furnace. To do this the ground around the furnace was excavated 5 or 6 feet, and a double row of 8-inch piles, S S, etc., 20 feet long, were driven each side of the furnace. These carried stringers, T T, and caps, L L, pierced in the center by a 4-inch hole to receive the jack-screws J J, etc. Meanwhile 15 heavy iron I beams, C C, were let through the side walls of the furnace, projecting out some 6 or 7 feet on each side. These were the needles. There were also four hard pine timbers 16 inches deep, laid across parallel with them. All these pieces were to support the side and middle walls. The cross walls were supported by four pairs of rails, D D, etc., laid across the needles under each wall.

Sixteen inclined braces, A, were set up on each side, bearing at F on plank and timbers laid across the ends of the needles and under the second line of horizontal brace rails R. To keep the foot of the braces from slipping out some hooks, H, of inch iron were carried from the planking at F to the lower line of the brace rails R. Thirty jack-screws, J J, etc., were then set on either side and brought to bear on hard pine beams I I, which came up and supported all the needles. The screws were turned up till all the weight was taken off the foundation, and the furnace was brought up to its original position.

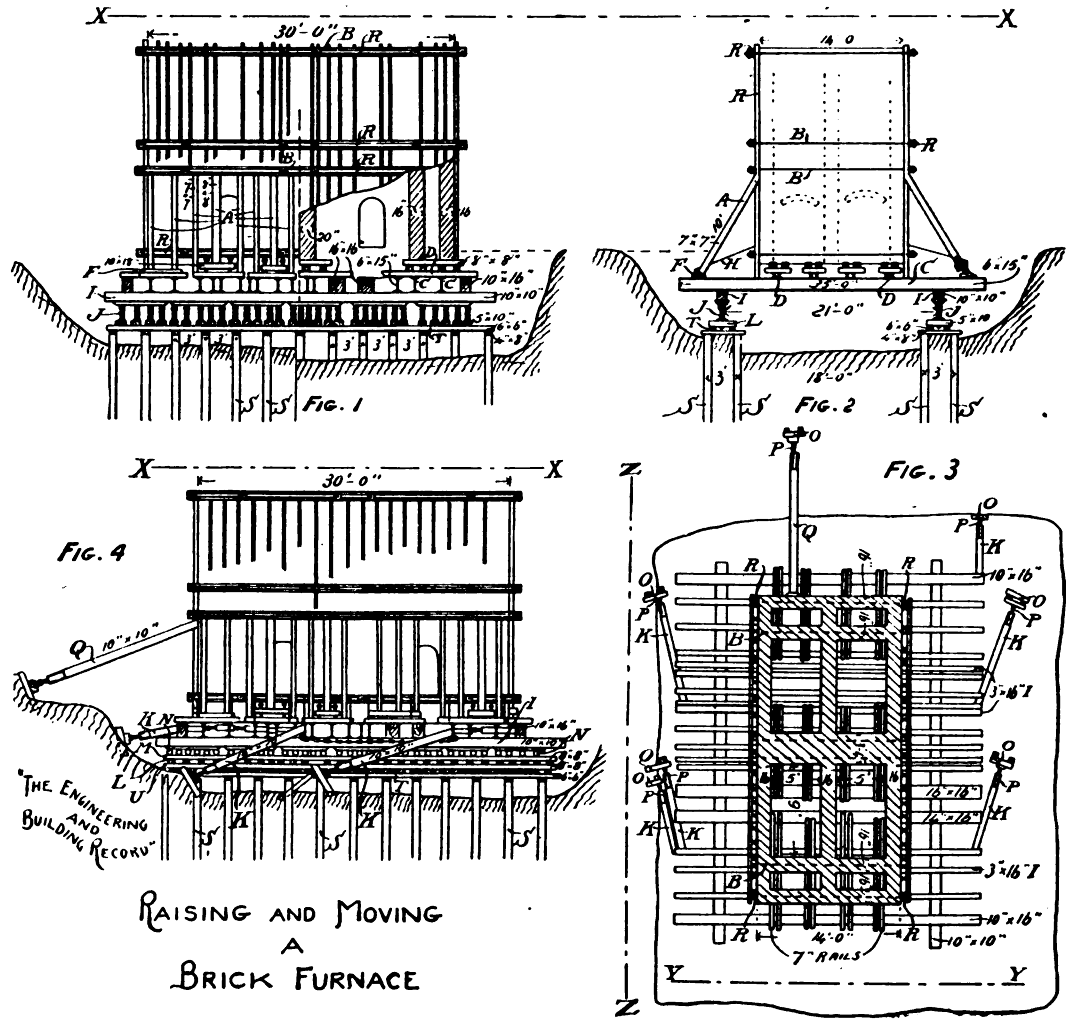
The old foundation was then removed and hydrant water let on for some hours to extinguish the fire in the cinder filling, so that the excavation would be carried down to the natural surface. Here a solid stone foundation was put in and brought up to within 20 inches of the bottom of the needles.

Four open spaces were left in this foundation 3 feet 6 inches by 9 feet to allow the mason to build up under the walls of the furnace; the spaces to be filled after the connections with the old work were completed and the needles taken out. Before this was done, however, the whole furnace had to be brought forward about 3½ feet. A line of timber U, Fig. 4. was laid each side of the jack-screws on the cross pieces L, and short 8 by 8-inch blocking was introduced between the screws, and a second line of stringers M, placed on top. Between these and stringers I were placed 32 6-inch wooden rollers N N, etc., on each side, and then the screws were turned down and removed leaving all the weight on the rollers.

The forward propulsion was obtained by setting braces K K, etc., against the ends of some of the needles, with foot-blocking, O O, etc., for solid bearing against the sides of the excavation. A jack-screw P P, etc., set in a hollow turned block of wood was placed between the end of each brace and its blocking. Blocking was also placed and wedged in between the ends of all the needles so as to carry the pressure uniformly and prevent their slipping. Another brace Q, was placed against the rear of the furnace and directly in the line of movement. When all was ready the jack screws P P, etc., were manned by three men each, and all turned together at given signals, each turn advancing the furnace about ¼ of an inch. The progress was about 1 inch in five minutes when everything was running smoothly, but as the rollers had to be changed and new blocking put behind the screws every time these were run out their full distance (14 inches), the average progress was about 1 inch in 15 minutes.

When the furnace was once in place the work of supporting it on the new foundation was simple and quickly done.

Isaac Blair, of Boston, Mass., executed the work of raising and moving the furnace.



RAISING AND MOVING A BRICK FURNACE

CLEANING A RESERVOIR AT NEW BEDFORD.

THE method used in cleaning the distributing reservoir of the New Bedford, Mass., Water-Works, was recently described by Superintendent R. C. P. Coggeshall before the New England Water-Works Association.

The reservoir has a surface form of a trapezium and covers an area of about five acres. The earthen embankments which compose its sides are 15 feet in width at the top, with slopes inside and outside of two feet horizontal to one vertical. The general dimensions through the middle are about 345 feet by 255 feet. The bottom is the natural surface left after excavation, and is gravel well filled with clay. The vertical height from the bottom to the level of the top of the embankment is 20 feet. A depth of 18 feet constitutes a full reservoir, and that volume contains 14,957,101 gallons.

During the month of April, 1888, this reservoir was drained for the purpose of making extensive repairs to the well of the gate-house, and also to the stone facing on the inside slope walls. While these repairs were in progress, the side walls and bottom were thoroughly cleaned.

At a convenient location on the south inside slope, a runway 4 feet in width was placed. Two-inch planking was used, and a ledge fastened to the sides to prevent the truck from slipping off. At the top of the slope this runway connected with a level plank platform, extending across the top of the embankment and continued to a convenient distance beyond the foot of the outside slope. Near the end of the platform and well beyond the outside slope was a hole of convenient size, through which debris was dumped some 15 feet to the ground beneath.

The runway on the inside slope allowed the use of a truck 2½ feet by 5½ feet, constructed of 2-inch planks, having three cross-pieces underneath 2 inches by 6 inches, and two cross-pieces on top 2 inches by 6 inches placed edgeways—one on the lower edge of the truck, the other in the middle. This allowed the placing of two tubs upon the truck at the same time for haulage up the slope without danger of either slipping. The truck ran on six large casters, having 4-inch wheels.

The haulage was made by means of a single rope spooling over a 4-inch derrick wench without gearing. This wench had a crank on each end and required two men to operate. A third man manipulated the slack of the rope. By this method the truck was operated with ease, and more rapidly than it could be done in any other way.

Six tubs were used. These were made from 50-gallon oil casks cut in two. For convenience in lifting handles were placed on opposite sides.

In eight days from the time the reservoir was discontinued from the distributing system the bottom was in condition for cleaning. Nearly all moisture had then evaporated from the material to be removed. A vegetable deposit, averaging from a quarter to a half an inch covered the bottom. At the foot of the slope walls, especially in the corners, there was found a large quantity of gravel which had become displaced from beneath the stone lining of the slope by reason of the continued wash of years upon it.

All the material to be removed was thoroughly scraped into convenient piles and then transferred to the foot of the runway by means of wheelbarrows. Here it was placed in the tubs, they being upon the truck. The truck was then hauled to the top of the slope and run along the platform to the hole near its end. The material was then dumped, and the truck, together with the tubs, quickly returned to the bottom of the slope The dump heap thus formed beneath the platform was afterwards removed by carts.

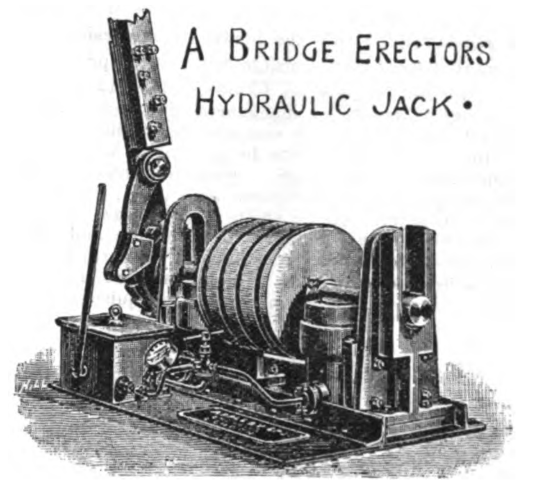
BRIDGE INSPECTION IN AUSTRIA.

ACCORDING to the Paris *Chronique Industrielle*, a decree addressed by the Government Inspector General to all Austrian railroads in regard to bridges, calls especial attention to the following points: Preventing any accumulations of moisture on the structures, search for loose rivets and bolts and opening of built riveted members, repainting around new rivets, special examination of box and plate girders, provision of new and free operation of old drainage holes, the removal at least once during its life of wooden sleepers in iron trough girders, the painting of the girders and the interior inspection of box and tubular girders. Especial care is taken to detect and prevent rust, since it caused the destruction of the Mahrisch-Ostray suspension bridge.

A BRIDGE ERECTOR'S HYDRAULIC JACK.

THE Excerpt Minutes of the Proceedings of the Institution of Civil Engineers contain a description by C. J. Appleby of a special hydraulic jack used in launching a railroad bridge 525 feet long (in three spans), weighing 340 tons, across the Rio Jauchy River in Brazil.

It was much more convenient and economical to deliver the materials and rivet up the bridge complete on one side of the river than to carry on the work on both sides. Staging, or floating lifting arrangements, were alike impracticable, and as the front end of the bridge might "sag" a little, adjustment was made by ten twin hydraulic jacks. Each pair was mounted on a strong wrought-iron bed-plate, with shackles for lifting, and bolts for securing the bed-plates to the staging, abutments, or piers. Each pair of jacks was provided with differential pumps. The pump of larger diameter was, of course, used for running up quickly, or for light loads, and the smaller one for the maximum duty, but could be worked by one man. The object in having one pump to each pair of cylinders was to ensure both rams being maintained at the same height. The heads of the rams were used as bearings for a steel shaft carrying a roller about 2 feet in diameter, which was grooved to take the heads of the rivets and thus give the bottom flange of the girder a fair bearing and good rolling surface; the end standards were merely intended to keep the shaft in its proper position. As there might possibly be a load of 120 tons on the roller each jack was tested to 100 tons, or 200 tons for the pair. The main girders being ready the jacks were set under them and lifted the completed section high enough to allow its packing to be removed and used for the next section. Then two men at each jack, working by signal on the pawl handles, propelled the bridge across the water to its position on the bridge seats.



If the front end was too low to ride over the rollers fixed on the piers or abutment it was quickly raised by the jacks. The bridge was launched considerably under the estimated cost.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

REPAIRS TO MACADAM ROADS.

AUSTIN, TEX., July 19, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: I beg to forward the following remarks on Mr. Owen's article on "Repairs to Macadam Roads," published in your issue of the 28th ult.

Mr. Owen states he builds his roads so that "they may wear down uniformly." Uniformity of wear over a road is another phrase for uniformity of traffic over its whole surface; the terms are synonymous. Granted this uniformity of traffic, and uniformity of wear is its natural consequence. There will then be of course no need for patching. As soon as the road under this uniform traffic is worn to the limit of safe bearing, the renewal of its entire surface is in order; and thereafter, even wear and entire renewal will follow in regular order, *ad infin*. The difficulty, however, that presents itself to me is, how on country roads to insure or effect this uniformity of traffic and consequent evenness of wear. It is simply impracticable. The rule of the road, which obliges a driver to keep to his right, will, to avoid the inconvenience of pulling aside for every passing vehicle, cause him to always keep to his right-hand edge of the road. Thus, there will be on all country roads four special lines of wear, corresponding to the space between the wheels, and the ingoing and outgoing traffic. Again, though great attention bestowed on a road surface during its first construction will insure, *cæteris paribus*, greater uniformity of wear, yet it will happen that on a road of many miles in length, a few stones will become loosened here and there per mile, or a few pieces of softer material inadvertently slip in, causing in each instance a tendency to form a hole of more or less size by the action of every wheel passing through it. Thus, from the causes mentioned, ruts and holes will occur and must be repaired, or, in other words, patched, to keep the road in good order. My remarks in regard to ruts do not apply to the streets in a city. Here the continual change in the line of movement of every vehicle produces a more uniform wear of the street surface.

Mr. Owen objects to steam rollers It would be a waste of power to use a 15-ton steam roller on the repair of a rut or patch. For such repairs a 2-ton roller will suffice. But for the original construction of a macadamized road, and for general repairs or entire renewals of the surface, a steam roller is far more efficient and economical than a two or four ton roller drawn by horses.

As to the use of clay or loam instead of broken stone screenings: In this, as in general, the better the material the better the result. Stone screenings will bind better with its own larger material below than will clay or loam. Every shower of rain will soften the clay and destroy its binding effect. At the same time only as much hard screenings should be used as will fill the interstices of an already rolled road. A little experience will determine this quantity. The size of the road metal should be such as to pass through a ring one and a half inches in diameter.

Lastly, as to Mr Owen's method of consolidation. To quote his own words, "the result is at first ruts and unevenness," which, to continue his statement, is overcome and remedied by a great deal of extra care and labor. Whereas by the method of consolidation described by me in my prize essay on Road Making, published in your issue of the 12th and 19th of April, 1890, the road surface will not require the extra care and attention to remedy the evil of "ruts and unevenness" in a newly made road. If Mr. Owen had 200 or 300 miles of road to maintain, in addition to his other duties as civil engineer and architect of all the public buildings in his State, he would not have the time to give this double attention to road construction, but would perfect his road at the first effort. In India road construction, which is here in its infancy, has been reduced to a science under the experience of 100 years of road making. The government there also owns the soil as landlord, and it considers it an economic policy to provide efficient communication throughout its vast estate, containing 275,000,000 of inhabitants, both as feeders to the railroads and for the general traffic and convenience of its vast population. It thereby increases the value of its own property by the enhancement of the value of the land, thus legitimately increasing its revenues and benefiting its subjects. The country roads in India are kept in better condition than are the streets of the great majority of American cities.

I. F. POPE,
Civil Engineer and Architect.

CRESSON SPRINGS, CRESSON, PA., July 26, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: I have read with much interest Mr. North's and Mr. Owen's remarks on road building in your issues of June 28 and July 12, and while agreeing with the statements made by both gentlemen in several particulars in regard to the subject at issue, I am obliged to differ from them in some slight respects. The fact is, I think some of the views are somewhat extreme in both cases. Our experience, for instance, in the construction of roads in Fairmount Park would indicate that there are many occasions where a steam roller is an almost indispensable tool for the proper and economical construction of Macadam and Telford roads, and there are other cases where, from local circumstances, a horse roller may be desirable. I do not think that an excessively heavy roller, say 20 tons, is as desirable or as efficient as one of, say about ten tons, for reasons which are obvious now to engineers of experience in road construction. We have found that good hard angular trap rock makes the best road, and that it is not desirable to use such a heavy roller as will round off the angular edges of the metal; a more firm bond is evidently made between the materials forming the road if the edges and angles are wedged into each other than if the stones are crushed and rounded by excessively heavy rolling. In regard to the surfacing with trap rock screenings, we find that by all odds it makes the best finish, but we do not use more than about half an inch of it, and previous to spreading it have found it always necessary to give the stone a slight coating of clay to act as a matrix between the stone. We generally use this clay in the form of a dry powder and sow it over the stones, then sprinkle the road with a watering cart, and then roll either with steam or horse roller depending on circumstances. It is hardly necessary to say that in grading for the road we cut out the cross-section to subgrade in the same form as the finished road surface is to be, and compact the bed thus made by thorough rolling.

RUSSELL THAYER,
Chief Engineer, Fairmount Park, Philadelphia.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department.* Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

DRY AIR REFRIGERATION.

REFERRING to our recent reply to an inquiry concerning ammonia refrigeration, F. M., of Jersey City, N. J., writes: "Will you make the necessary calculations for me showing how to determine the amount of air to be compressed and subsequently expanded to get a given cooling effect?"

[Briefly stated, we may proceed as follows: Suppose we wish to freeze water having a temperature of, say, 60° Fahr. The amount of heat to be taken from a pound of water at this temperature to reduce it to ice at 32 degrees is 170 heat units. This becomes clear when it is remembered that the latent heat of fusion of ice, or the amount of heat to be taken from a pound of water at 32 degrees to transform it into ice at 32 degrees, is about 142 heat units, and that cooling of water from 60 degrees to 32 degrees involves the abstraction of 28 units. One pound of air at one atmosphere, and 60 degrees compressed to two atmospheres, is heated through about 116 degrees.* Multiplying this by 0.238, the specific heat of air, we have 27.6 heat units per pound of air. Hence to freeze a pound of water from 60 degrees requires $\frac{170}{27.6} = 6.16$ pounds of air, which is equal to about 81 cubic feet at one atmosphere and at 60 degrees. Now to compress one cubic foot of air to two atmospheres requires about 1,630 foot-pounds of work. Therefore $1,630 \times 81 = 132,030$ foot-pounds, or total required to compress 81 cubic feet to two atmospheres. A horse-power being equal to 33,000 foot-pounds per minute, one horse-power would, therefore, produce $\frac{33,000 \times 60}{132,030} =$ about 15 pounds of ice per hour. If 33 per cent. be deducted for friction of air compressors, etc., and allowing, say, 5 pounds of coal for a horse-power, we would have $\frac{10}{5} = 2$ pounds of ice per pound of coal burnt under a boiler.]

BOOKS ON BUILDING, ETC., WANTED.

A PHILADELPHIA correspondent writes: "I am desirous of receiving a complete book on building houses, factories, etc., one that gives all the technical terms known to the builder; also a book definitely describing the use of the engineer's level and transit. Have you such?"

[Our correspondent would probably do well to begin by providing himself with Kidder's "Architects' and Builders' Pocket Book," price $3.50, and with Trautwine's "Civil Engineers' Pocket Book," price $5. These will most likely tell him all he wants to know about building and architectural terms, and the construction and use of surveying and leveling instruments, and a great many other things besides, as they are standard works in their respective departments. For instruments only, perhaps Gurley's "Manual of Surveying Instruments," price 50 cents, would answer all purposes. In designing and superintending the construction of buildings Hatfield's "American House Carpenter," price $5, (which embraces much more than carpenter work, by the way,) and Clark's "Building Superintendence," price $3, will be found very helpful. Garnsey's "American Glossary of Architectural Terms" would probably tell our correspondent all he wants to know about them. Gillespie's "Surveying," price $3.50, and his "Leveling," price $2.20, describe at length the construction and use of the instruments.

Any of these books will be sent by the Book Department of this journal, postpaid, on receipt of price.]

PAINTING FLOORS.

ACCORDING to a French journal painting floors with any color containing white lead is injurious, as it renders the wood soft and less capable of wear. Other paints without white lead, such as umber or sienna, are not injurious, and can be used with advantage. Varnish made of drying lead salts is also said to be destructive, and it is recommended that the borate of magnesia should be used to dispose the varnish to dry. A recipe for a good floor varnish is given as follows: Take two pounds of pure white borate of manganese, finely powdered, and add it little by little to a saucepan containing ten pounds of linseed oil, which is to be well stirred and raised to a temperature of 360° Fahr. Heat 100 pounds of linseed oil in a boiler until ebullition takes place, then add to it the first liquid, increase the heat, and allow it to boil for 20 minutes. Then remove from the fire and filter the solution through cotton cloth. The varnish is then ready for use, two coats of which may be used with a final coat of shellac, if a fine polish is required.

DE SAINTIGNON'S DIFFERENTIAL PYROMETER.

BEARING on the recent inquiry in our columns concerning a pyrometer for high temperatures, the following particulars of De Saintignon's differential pyrometer will prove interesting. They are taken from the Excerpt Minutes of the Proceedings of the British Institution of Civil Engineers, and were originally given in *Le Génie Civil.*

The pyrometer in question determines the temperature of a furnace by exhibiting the rise in temperature of a constant stream of water made to circulate through a copper pipe inserted in the furnace. It consists briefly of a short copper pipe called the "explorer," which is inserted into the furnace, and into which a stream of water descends from a reservoir through an india rubber pipe, passing on its way through a filter. From the explorer the water is taken off by another india rubber pipe to a small glass stand-pipe, from which it is discharged by a cock. The object of the stand-pipe is to enable a constant flow to be maintained by adjusting the cock so as to keep the water-level in the stand-pipe constant. The stand-pipe is graduated so that instead of altering the cock the level may, if preferred, be read off and the proper corrections made. Before and after entering the explorer the water passes around thermometers. If the zero of the second thermometer is made to coincide with the reading of the first, then the desired temperature of the furnace can be read off directly, for with a constant flow of water the rise in temperature for the same instrument is proportional to the difference of temperature of the furnace and of the water, and one experiment will suffice to determine the scale for the second thermometer. To avoid the influence of the furnace walls the explorer should be inserted through an "isolator," which is a tuyère supplied from the same reservoir as the pyrometer.

The pyrometer may also, by means of a thermo-pile, be made to transmit its indication by electricity to a distance, and exhibit them on a graduated galvanometer.

Novelties.

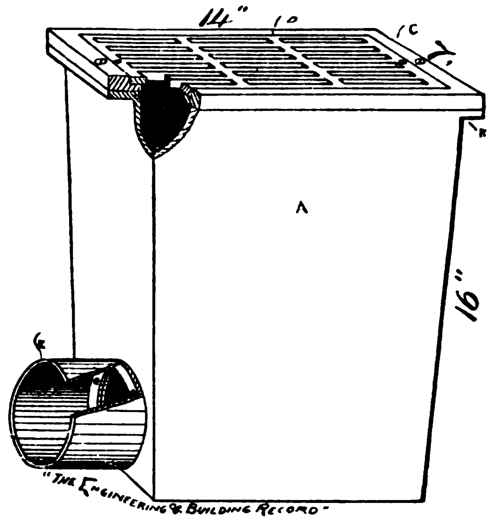
Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course, be understood that the selection does not imply indorsement.

A FRESH AIR INLET.

THE sidewalk inlets for fresh air to sewer traps frequently consist of a small brick chamber with an iron grating over it into which the end of the vent pipe is cemented or loosely inserted. The brickwork is likely to be poor and perishable, and almost sure to be injured or destroyed by sidewalk repairs, etc., sooner or later. For greater convenience, tightness and durability than the brick construction usually affords, a cast-iron box A, shown in the accompanying illustration, has been designed, which rests by its flange B in a hole cut through the pavement. The top plate C is cast separate from the box and is galvanized, as is the grating D, which can be easily removed. The flange thimble E is bolted to the box and receives the vent pipe, which is firmly calked in.



FRESH AIR INLET

This box is made by the J. L. Mott Iron Works, 88 Beekman Street, New York, and was first used by Paul S. Bolger, master plumber, Madison Avenue, New York.

STREETER'S PATENT PIPE-LOWERING APPARATUS.

FIGURES 1, 2 and 3 show the apparatus designed by Daniel A. Streeter, Waterbury, Conn., as an improvement on his methods of pipe laying that have been described in this journal on pages 262 and 273, Vol. XX. Figure 1 is a general view of the apparatus in position ready to begin moving and lowering the pipe; Fig. 2 is a cross section of the trench with the pipe sustained over it ready to be lowered, and Fig. 3 is an elevation from Z Z, Fig. 2, of the latch detail. The main beams C C are adjustable on standards A A, and each carries a sliding frame F composed of two iron straps *a* and *b*. These beams C C are placed across the trench as shown, and frames F are set just beyond the center of the trench and support the ends of the short skids E and E. The ropes M M are fast at one end to frames F and F, are led through snatch blocks under beams C C, and have the other end free. The ends of the pipe D are slipped into the bights V V, and, when the free ends of the ropes are hauled in, the bights shorten and roll the pipe up on the skids E, as shown in Fig. 2. If the latch rope L be now pulled it will trip the catch K and, releasing the cross-piece G, allow the skid E to drop or be removed while the pipe remains suspended in the bight of the rope L, by which it can easily be lowered by slacking off the free end.

MEASURES for smoke prevention are just now attracting a good deal of attention in Germany also. The united architects' and engineers' societies have taken the matter under consideration. In Saxony a government appropriation of $1,700 has been made for practical tests of smoke preventing apparatus.

---

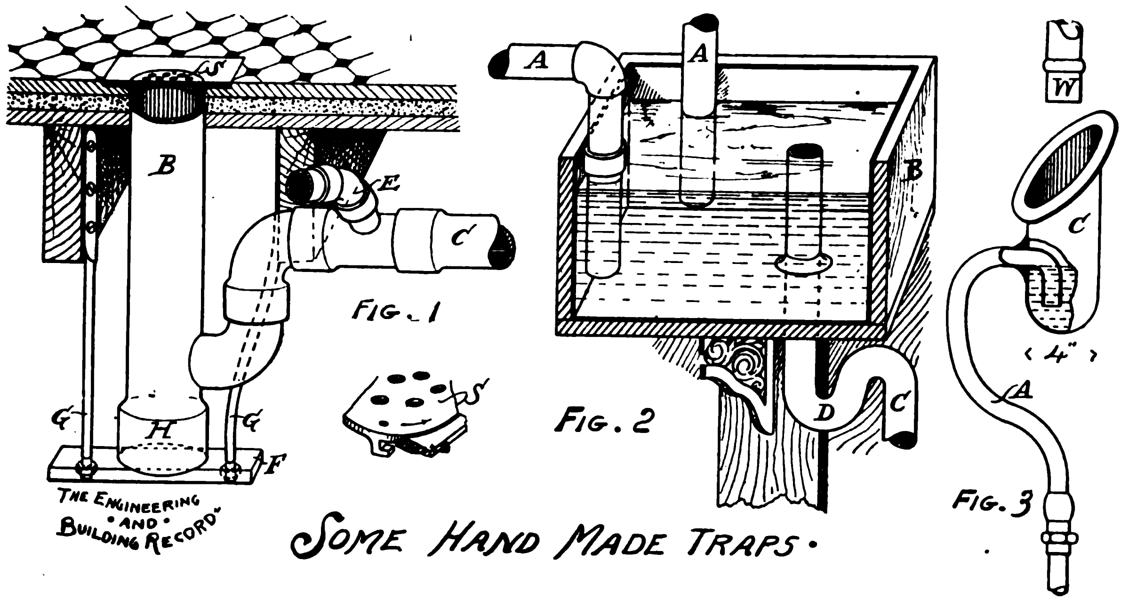
* Tables in engineering hand-books will give the temperatures for certain degrees of compression. They may be calculated, if desired, by different formulæ.

DOMESTIC PLUMBING HEATING LIGHTING & VENTILATION ENGINEERING

• SOME HAND-MADE TRAPS.

ILLUSTRATIONS of simple traps made by hand from the commonest materials, and adapted for special requirements, may give some hints to plumbers who are accustomed to find almost every fitting ready-made and catalogued, or may suggest devices for isolated places where special fittings are hard to get.*

Figure 1 shows a trap made to receive the floor drainage from a saloon. The 5-inch strainer plate S is daily removed, and cigar stumps and other rubbish swept into the trap, which therefore needs special provision for cleaning and for free discharge. This was secured by using a 6-inch Y bend B 22 inches long for the barrel. The 4-inch waste pipe C was calked to the elbow D, and had calked joints for the tee and ⅛-inch bend connection with the 2-inch vent pipe E. The lower end of the bend B had a calked stopper, and was supported from the floor joist by the 4 by ¼-inch iron plate F and ½-inch gas pipes G G. This trap had a very deep seal, and below its outlet a space at H to hold the sediment and heavy rubbish which could be readily removed when the strainer plate was taken off.



SOME HAND MADE TRAPS.

Figure 2 shows the double trap protecting the refrigerator drips A A in the same building. These drips discharge into a small copper lined box B fastened to the cellar wall. This box is emptied through a pipe C to the sewer. Sewer gas is trapped at D, while the pipes A A discharge below water level so that their ends are sealed against an upward current that would permit the circulation of cellar air in the refrigerator.

Figure 3 shows a drip cup on the basement wall of a down town office building. W is a waste pipe from a toilet-room floor safe, and A is the discharge to the sewer. The cup C is made of 4-inch lead pipe, flanged out at the top and closed at the bottom. The outlet is placed so as to discharge the water without taking either sediment or floating scum, both of which can be conveniently removed through the open top.

The above described articles were made by Colin Campbell, 158 East Forty-fifth Street, New York City.

HEATING AND VENTILATING SCHOOL-HOUSES.

SEVERAL months ago a series of papers describing some of the prevailing methods of heating and ventilating school-houses was presented to the Boston Society of Civil Engineers by William E. McClintock, Theo. P. Perkins, and Prof. S. H. Woodbridge. The papers are given in full in a recent issue of the *Journal* of the Association of Engineering Societies, from which the extracts given below have been made. Mr. McClintock, among other things, says:

"The normal amount of carbonic acid in the air is from three to five parts to the 10,000, while an addition of two to four parts makes a perceptibly bad impression. While we may not arrive at perfection in this matter, we can approach to a point that may be said to be safe. On authority of such able men as Dr. Parks, of London, and Surgeon Billings, of our own country, the general practice of to-day is to call ten parts of carbonic to the 10,000 the maximum allowable amount in a room where many persons are assembled together. The air as it is exhaled from the lungs leaves the mouth at a temperature of about 100 degrees; and although the carbonic acid in the exhaled air is great, yet the loss in density caused by the increase in temperature is sufficiently great to cause the air to rise toward the top of the room, where it rapidly mixes with the other air, gradually lowering the standard of the whole room.

"This carbonic acid gas has at times been a stumbling block to many, and has, in the past, given rise to a theory that the only way to ventilate a room was to furnish openings at the floor and allow the heavy gas to flow off like water. Although such a condition might exist in a room very near air-tight and with a temperature unchangeable, yet where the temperature is at all changeable the different gases must mix thoroughly. It strikes me that the problem sought is rather one of how much of the bad can we take mixed with the good and how shall we introduce the good and get rid of the bad. I find, after wading through long arguments, where all the conditions are considered, that if we can get from 25 to 30 cubic feet per minute per scholar we are getting very good results, and we can keep the carbonic acid to the required ten parts in 10,000.

"It is the purpose of my paper to rather give some of the methods of heating and ventilating to be found at the present time than to theorize. I shall first refer to a church which has a seating capacity of 750 and an air space of about 150 cubic feet per person when full. There is a round ventilator in the center of the ceiling connected by a box with a brick tower having a window on each of its four sides. The box has a cross section of 3¼ square feet, and with the ordinary velocity of, say 3 feet per second, would allow about 35,700 cubic feet per hour to pass off. This amount, with the air space above referred to in the room, would seem to give very fair results; but on several occasions that I looked at the outlet box I found the damper in it closed. I at last succeeded in inducing the sexton to keep this damper open, but even then the results did not change. I then went to the tower and found that the large windows before referred to were entirely boarded up on the inside, leaving no chance for air to pass either in or out. By removing the boards from these windows we now have a fair flow of air. I find on an examination that most of our churches have this method of ventilation, which must be very extravagant, to say the least, as the heat passes from the registers in the floor directly up and through the roof, to the extent of the capacity of the outlet box. In addition to the extravagant feature of this method as to fuel, there is the worse feature of leaving all the corners with but very little pure, or even warm, air in them.

"I call to my mind some school-houses that I have looked over. A brick building having 12 rooms was actually planned to have two 20-inch flues for ventilation, having a 15-inch iron smoke-pipe passing up the center to give the needed power or draught. Each room was to be connected into the common flue, with no means of preventing the air from passing from one floor to another. The heat was to be direct steam. To get any decent change of air would require a velocity in the flues of about 50 miles per hour, even provided there was any air in the rooms to take out. After long discussions this plan was so changed by the committee having charge as to give good-sized flues from the rooms, while fresh air was taken direct from outside and passed over steam radiators located in the room to be heated. I am unable to give any figures at this school, but do not think they would be wholly satisfactory.

"A wooden four room building I examined had 8x12 brick flues for the lower floors, while the upper floors used the unfinished breasts beside the chimney for ventilators. On closer examination the breasts were found to end in the attic with no openings from attic to outer air. In these cases the air flowed through the registers at a velocity of about two feet per second, which, taken with the size of the flues, would give only 5 or 6 cubic feet per minute per scholar.

"A two-story four-room brick building seemed to have small registers into brick flues 8x12 inches, two rooms using a common flue. The air here was simply unbearable, and an inspection in the attic showed that the brick flues were built on the same principle as a cannon—viz., with hole at one end only. A two-story wooden building of two rooms had a very small flue and a still smaller register. The theory in all the older types of buildings seemed to be to get a register at any cost, and never mind the flue.

"I shall now have a word to say of some of our more modern buildings—buildings that have very pleasant exteriors as well as interiors, buildings that have been planned by so-called architects who should never have been permitted to foist such abortions on a long-suffering public. A fourteen-room brick building, with hall, was heated by hot-air furnaces, with no extracting flue worth mentioning. Much fault was found with this building by the parents on account of headaches and other ailments among the children attending the school.

"A two-story four-room building of wood, as originally planned by the architect, showed a 10-inch square wooden flue that could not be built on account of the valley rafters; and even if it could have been built it was to end in the open attic without openings of any kind to the outer air. The changes in original plan delivered the four flues from the rooms into a cupola with no more than one-half the sums of the four sections. This building was heated by direct steam by the use of lines of pipes around three sides of the rooms.

"A building of exactly the same plan as the last was planned to be heated by hot-air furnaces, with plaster-finished extracting flues ending in a close attic, which later on were carried into a cupola. Direct steam was put in instead of hot air.

"An eight-room two-story wooden building, located in a beautiful spot, with cheerful and finely finished and furnished rooms, was heated by the same lines of steam pipes on the three sides of each room. The ventilation is by tin pipes in each of the outer corners of the building and registers at the top and bottom of each room. The lower rooms have 8-inch pipes extending to the attic floor. The upper rooms have 12-inch pipes starting at the second floor and placed outside the smaller pipes. The outer pipes from one-half of the building join into a pipe of the same size (12-inch) and end in a brick flue having a 12-inch glazed pipe passing through the center for a smoke-pipe. The required velocity of the air in this 12-inch pipe, as it enters the brick flue to change the air of its part of the building in, say, 20 minutes, is 45 feet per second. The required velocity in same pipe to ventilate but *one* room is a little more than 10 feet per second. The actual observed velocity in the pipe was from 2 to 3 feet per second.

"A four-room two-story wooden building has the same line of steam pipes on three sides of the rooms. The ventilation in this building is by 12-inch tin pipe from each room, the same entering a common brick flue 3 feet by 2 feet in the attic and having a glazed smoke-pipe passing through the flue. The main defect here is the entire lack of any means of admitting fresh air.

"A twelve-room two-story building, heated by hot-air furnaces, had no extracting flues except some old and disused chimney flues about 8x10 inches with registers near the top of the rooms. The basement of this building was partitioned off into a series of rooms, and a large quantity of rotten wood added its smells to the water-closet tanks to sweep through the whole building.

"I could easily cite many other cases equally bad as the ones already referred to, many of which will probably continue to exist until some power other than the local boards order the changes made. There is no doubt but that heating and ventilating must go hand-in-hand; they cannot be separated; and no great improvement can be made unless one conforms to the other.

"*First.*—We cannot introduce fresh air in any quantities into a room without first removing an equal quantity of the air already in the room.

"*Second.*—We cannot take air out of a room unless we introduce an equal volume.

"*Third.*—We cannot keep the air of a room good unless we introduce enough fresh air to mix with the air already in to thoroughly dilute the same and keep it to a certain standard.

"*Fourth.*—In the introduction of fresh air we must avoid cold draughts, which means the introduction of large quantities of air at about the required temperature and through a flue of sufficient section to give a low velocity.

"*Fifth.*—The warm-air inlet and cooled outlet must have such relation to each other as to compel the air to thoroughly mix and intermingle in all parts of the room with but slight variations in temperature."

(TO BE CONTINUED.)

---

* Original and ingenious little details of handwork are alway interesting to the mechanic and designer, and this journal would be glad to receive such pencil sketches and descriptions from journeymen readers for publication in this column, as specimens of handwork.

STEAM-HEATING IN THE MECHANICS' BANK BUILDING, NEW YORK.

PART I.—ARRANGEMENT OF EXHAUST MAINS, BOILER-FERD HEATER AND WARMING FRESH-AIR BLAST.

THIS building* is heated throughout by direct radiators, supplied mainly from the exhaust steam from the various pumping, elevator and dynamo engines.

The board room and bank offices or the first and second floors are supplied in winter with warm air, besides their radiators.

Figure 1 shows the general arrangement ot steam-pipes in the engine-room. Exhaust steam from all the engines is collected in the main A, whose branch B connects with the Berryman feed-water heater Z, and whose branch C connects with exhaust main D, which terminates at one end in the smoke-stack, and at the other in the distribution main F that supplies all the radiators. A branch, not shown here, from F to the boiler, is controlled by a valve *t*, and can supply live steam to any part of the system.

Ordinarily, the heater Z and all the radiators are supplied by the exhaust steam, and the back-pressure valve *e* is set at ten pounds, valves *b*, *f* and *g* are open, and valve *c* is closed, then steam passes through heater Z and into main F, any pressure above ten pounds escaping direct to stack through valve *e*; if the exhaust pressure falls below ten pounds, the regulating valve *t* opens and admits live steam until the pressure reaches ten pounds. Closing valves *b* and *g*, and opening *c* cuts out heater Z, and supplies steam to the radiators only; closing *f* and *c* and leaving *b* and *g* open, cuts off the radiators (as in very warm weather), and supplies the heater only, and closing *b*, *g* and *f*, and opening *c* and *e*, cuts out both heater and radiators, and discharges exhaust directly into the stack. The heater receives cold water through pipe Y, and delivers hot water to the boilers through pipe X. *q* is a safety valve, *a* a hand-hole, and U a steam trap.

"THE ENGINEERING AND BUILDING RECORD"

V V are drip and sediment pipes, and W W are the legs supporting the heater. *d* is a grease trap. *m* is an 80-inch Sturtevant blower which receives air from above the roof through the galvanized iron conduit *n* and delivers it at a pressure of about one ounce through conduit T and branches N N, etc., to the board rooms and bank offices on the first and second floors. There are several branches N, each of which opens freely at *i* into a box L which contains a steam radiator that takes steam through J and discharges it through K.

Box L communicates at *k* with the conduit M to the room which constantly receives the fresh-air blast, whose temperature is regulated by the damper S, that is automatically controlled by a thermostat and electric pneumatic valves, to be described hereafter. The blast from N always enters freely into box L; if the damper S is down, as shown, the blast passes out of box L (where it has been warmed) through *k* to conduit M; if S be turned straight up it closes branch *k*, and though the blast can enter L it cannot escape, and so passes outside of it, from N to M, and is delivered cold; if S is partly raised the hot and cold air is mixed, and different temperatures may be secured in M. H is a relief pipe.

Figure 2 is a section through the Berryman heater, to show its connections more clearly. *o o* is asbestos jacketing.

The figures are not drawn to scale, being intended only to illustrate the system. Pipes A B C D and E, Fig. 1, look disproportionately large on account of being shown jacketed, while the others are not covered.

(TO BE CONTINUED.)

STEADY progress is being made in the raising of the tracks of the Pennsylvania Railroad above the street level, at Jersey City, N. J.

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

WHEN IS IT ECONOMICAL TO USE EXHAUST STEAM FOR HEATING?

J. H. B., Beckleysville, Md., writes: "Have just been reading Baldwin's work, "Steam Heating for Buildings," and find it interesting reading, though not giving much relative to exhaust steam for boiling purposes. This, however, may not be relative to the subject, and if not objectionable to you may I ask the following of your paper: I have been somewhat puzzled as to using exhaust steam for boiling stock in our paper mill in open tubs, and wish to know,

(1) If all exhaust would be necessary to maintain circulation, would it be cheaper than using live steam?

(2) Would it be cheaper if a condenser were used on the engine and live steam used for heating?

(3) Could exhaust be used economically in a rotary boiler?

(4) In mill are two tubs about 8 feet diameter and about 9 feet high, nearly two-thirds filled with cold water. In center of movable bottom was an upright trough covered on top but perforated near top with large openings and smaller ones below water level. Water was forced up by the exhaust steam and out over contents of tub and thus a circulation and distribution of hot water was maintained. Check valve prevented water going back to engine cylinder. Have been using, however, only plain slide valve engine."

[(1) If you can do your work with the exhaust steam, it is nearly always cheaper to do so than to take live steam directly from the boiler. A pound weight of exhaust steam has practically the same heating value as a pound weight of live steam. The only case in which it can be cheaper to use live steam is when the quantity of exhaust steam required is very small, for instance, to warm a small radiator in an office, or a glue kettle, or some such trifling apparatus, it would be foolish to throw two pounds back-pressure on a large engine, say 100 horse-power, when the two pounds back-pressure would be equivalent to the loss of about four horse-power in the engine. When the steam required for heating exceeds the four horse-power, however, from this point on the economy of using the exhaust steam becomes greater and greater.

(2) The reply to your second question is somewhat similar to your first one. If you use a condenser you will make the average engine from one-fifth to one-third more powerful, according to the point of cut-off and the mean-pressure of steam in the cylinder. So that assuming your engine to be 100 horse-power (non-condensing), you may make it develop 125 horse-power by the condenser, or, you may get 100 horse-power out of it for eight-tenths of the steam you formerly used, and assuming the latter to be the fact you will save 20 horse-power by the condenser, and should the amount of steam required for heating be considerably less than 20 horse-power, why then, use a condenser and use live steam for heating. If, however, it is greater than 20 horse-power, from that point onward it would be as foolish to run your exhaust steam into the atmosphere, when you require it for heating air or warming water, as it would be to throw your fuel in the river.

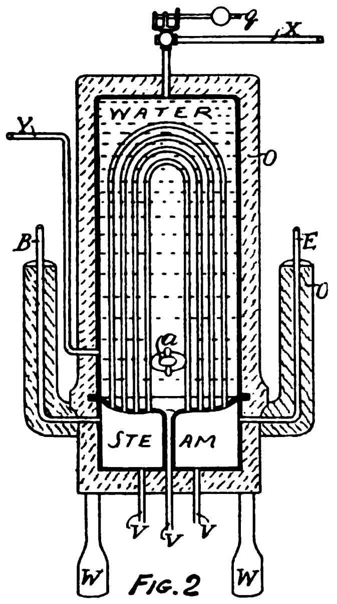

Fig. 2

(3) Exhaust steam can be used in a rotary rag boiler if the temperature is sufficiently high to disintegrate the rags. There is no other objection.

(4) We would arrange the connections from engine to tubs in such a manner that the condensation would not flow back on engine, by carrying the pipe first upwards and then down to the tubs. We would also use a back-pressure valve on the roof connection, so the excess of exhaust steam would pass off by that direction.]

TRADE PUBLICATIONS.

SEWER VENTILATION.

ARCHIBALD FORD, Assoc. M. Inst. C. E., and E. G. Wright, Portsmouth, England, have sent out a pamphlet, entitled "Sewer Ventilation," in which they illustrate and describe their patent ventilating sewer and drain pipe, and system of sewer and drain ventilation. The nature of the invention is presented in an interesting manner and the advantages claimed for it are pointed out.

THE work of laying the cable for the Broadway Railroad will be commenced at an early date. Plans and specifications have been filed.

---

* A general description of the building was given on page 11.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ARCHITECTURAL COMPETITIONS.

VALPARAISO, IND.—The German Lutheran congregation will erect a church at a cost of $10,000. Plans have not been made. Architects may address Claus Specht, as above, for particulars.

CONTRACTING INTELLIGENCE

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." *Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.*

For works for which proposals are requested see also the "Proposal Columns," pages i-ii-142.

WATER.

For Additional Water Items see Proposal Column

ALGONA, IOWA.—City Clerk W B Quarton writes: "The city is now sinking a well for water supply, and as soon as completed will then need the other necessary things to complete the system, such as water mains, pumping machinery, etc. We will then issue bonds for $10,000 and negotiate the same. The city has no other indebtedness and therefore bonds will be first-class."

HOQUIAM, WASH. — John Richardson, Chairman of the Committee on Fire and Water, writes: "We contemplate putting in a water-works plant, but as yet have not got plans and specifications. Making a rough estimate, we think it will cost something like $30,000 or $40,000. If the town puts them in we shall have to issue bonds for the payment by three-fifths vote of the voting population."

ALEXANDRIA, LA.—The Town Clerk at this place writes: "An ordinance was passed July 11, 1890, granting a franchise to Henry Sour & Co., of Shrevesport, La., for the purpose of constructing, maintaining and operating a system of water-works and a system of sanitary and domestic sewerage for the term of 30 years."

BANGOR, ME.—The Eastport Water Company will largely increase the water supply at their reservoir. Work will be commenced at once.

VENICE, ILL.—The water mains at this place are to be extended. The Village Clerk can furnish details.

NEVARRE, O.—There is a movement at this place favoring establishing a system of water-works.

CENTRALIA, ILL.—The City Clerk at this place writes: "The proposition of submitting to the vote of the people the question of granting a franchise to erect a system of water-works in this city was voted down at the last meeting of the Council. There is some talk of the city erecting a system of its own, but no steps in that direction have yet been taken."

RUTLAND, VT.—Town Clerk C. B. Mann writes: "We have bought four acres more land and will enlarge the water storage soon, cannot state how soon."

RICH HILL, MO.—The Rich Hill Water, Light and Fuel Company will establish a water-works system at this place.

FROST, TEX.—The people of this place will soon establish a system of water-works. For further particulars address J. H. Galbreath, as above.

CINCINNATI, O.—The B. P. I. have given Superintendent Sharp of the water-works instructions to prepare plans and specifications and estimate of cost for four new pumps of ten million gallons capacity each. Proposals will be asked for as soon as the plans are finished.

FULTON, KY.—This town has voted to bond itself in $25,000, to build water-works.

CANTON, DAK.—It is reported that the people of this place have voted to establish a system of water-works.

WELLSTON, O.—This place has issued and disposed of bonds for the purpose of establishing a system of water-works.

NORTH BROOKFIELD, MASS.—The water-works system at this place is to be improved.

NEENAH, WIS.—It is probable that the water-works system projected for this place will be established at an early day.

GRAND RAPIDS, MICH.—It is probable that the projected improvements to the water-works system at this place will be made very soon, as the City Attorney now has the matter in hand.

WEBSTER, MASS.—The people of this place want water-works, and a system to cost about $75,000 is talked of.

SEATTLE, WASH.—The report of Consulting Engineer B. Williams, regarding the distribution system, has been adopted and the City Clerk has been directed to advertise for proposals for furnishing the following materials: Cast-iron pipe—8,000 lineal feet 30-inch pipe, 5,600 lineal feet 24-inch, 13,800 lineal feet 20-inch, 2,700 lineal feet 16-inch, 5,900 lineal feet 12-inch, 9,700 lineal feet 10-inch, 24,000 lineal feet 8-inch and 60,000 lineal feet 6-inch. Wrought-iron pipe—12,000 lineal feet 12-inch pipe, 6,000 lineal feet 8-inch, 4,000 lineal feet 6-inch; 300 fire hydrants, valve and valve boxes. About 170 tons of special castings will also be required.

ASHLAND, KY.—M. M. Tidd, C. E., of Boston, Mass., has been consulted in the matter of building a new system of water-works for this place.

HAMPTON, IOWA.—Regarding the contemplated water-works at this place, Recorder Charles Kray writes: "No action will be taken by the City Council until the question where to get the water is settled. When that is determined, and the city is ready to issue its bonds and let the contract, I shall write you."

SOUTH ORANGE, N. J.—Reports say that the authorities of South Orange have contracted for a supply of drinking water with the Commonwealth Water Company. The daily supply is to be 50,000 gallons.

WATER-WORKS.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following place: Goshen, Ind.

THE Editor of THE ENGINEERING AND BUILDING RECORD is always glad to receive items of news for the Contracting News Department. But such items are not considered news except when the prices and particulars of the award of a contract are given.

The announcement that ——— has sold ——— to ——— without giving the *prices* and particulars concerns only the buyer and seller. Such notices are always excluded, except in the case where a certain firm is stated to have taken a certain contract, the execution of which would require that they should buy certain materials. Such an item would be used if deemed of more than local interest, because it would suggest to some readers the possibility of their making a sale or securing a sub-contract.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

RICHMOND, VA.—The city will probably issue $75,000 of bonds for the construction of sewers.

NORTH BALTIMORE, O.—Two miles of pipe sewers are to be laid here soon. Address John P. Force, engineer in charge of the work.

GENEVA, N. Y.—The Geneva *Advertiser* is advocating the need of a thorough system of drainage and sewage.

GLOVERSVILLE, N. Y.—The following bids for the construction of certain sewers were received by F. E. Abbott, City Engineer, July 21: McDonald & Skinner, Little Falls, N. Y., $6,230.30; Frank Dwyer, Gloversville, N. Y., $6,732.35; Van Vranken & Duell, Schenectady, N. Y., $7,488.20; Salmon & Gray, Albany, N. Y., $7,778.65; Bennett & Doll, Utica, N. Y., $8,019.85; S. C Ferguson, Gloversville, N. Y., $8,128.55; A. P. Bovier & Beardsley, Elmira, N. Y., $8,162.15, John C. Miller, Amsterdam, N. Y., $8,210.00; M. J. McCann, Albany, N. Y., $8,755 00; Adam Miller, Saratoga, N. Y., $8,810.80; Troy Public Works, Troy, N. Y., $9,307.00; George W: Barlow, Seneca Falls, N. Y., $9,670.90; Wm. Huggett, Gloversville, N. Y., $3,407.47.

BOSTON, MASS.—The following proposals for the improved sewers, Section 3, outfall sewer, Squantum to Moon Island, were opened July 24:

BIDDERS.	ITEMS AND ESTIMATED QUANTITIES:										Total.
	a Earth Excavation and Refilling in Trench. 2,100 lin. ft.		*b* Brick Masonry in American Cement. 1,475 cub. yds.		*c* Brick Masonry in Portland Cement. 550 cub. yds.		*d* Concrete Masonry. 8,450 cub. yds.		*e* Dimension Stone Masonry. 2 cubic yards.		
H. P. Nawn, Boston	$10 86	22,806.00	$12.80	18,880 00	$14.00	7,700.00	$4.40	37,180.00	$20.00	40.00	$86,606.00
National Construction Co., Boston	10.20	21,420.00	12.80	18,880.00	14.85	8,167.50	4.65	39,292.50	45.00	90.00	87,850.00
Thomas A. Rowe, Newton	8.17	17,157.00	13.80	20,355.00	16.10	8,855.00	5.18	43,771.00	40.00	80.00	90,218.00
Aaron A. Hall, Boston	10.80	22,680.00	12.00	17,700.00	13.12	7,216.00	5.04	42,588.00	60.00	120.00	90,304.00
Perkins & White, Boston	13.00	27,300.00	11.80	17,405.00	14 00	7,700.00	5.00	42,250.00	35.00	70.00	94,725.00
James Killen & Neil McBride, Boston	11.00	23,100.00	13.00	19,175.00	14.50	7,975.00	6.00	50,700.00	25 00	50.00	101,000.00
Collins & Ham, Boston	13 00	27,300.00	12.60	18,585.00	15.00	8,250.00	5.75	48,587.50	50.00	100.00	102,822.50

Awarded to H. P. Nawn.

LEXINGTON, KY.—Our correspondent here writes: "This city wants plans for a complete system of sewers, pipe system." Address W. J. Hulihan, as above.

FAR ROCKAWAY, L. I.—Investigations are being made regarding the adoption of a system of sewerage for this place. President Jones, of the Sewer Commissioners, can furnish particulars.

KANSAS CITY, KAN.—The Kansas City *Times* of July 26, prints the following: "Alderman Kimball's plan to bond the city for $1.500,000 to pay for constructing within the present city limits a sewerage system commensurate with the pressing needs of the rapidly growing city for properly constructed sewers, is bearing fruit. He has not as yet formulated all the details of the plan and it is yet in embryo, but notwithstanding this, the Board of Public Works is at present discussing the sewerage question on the line of the plan proposed by Alderman Kimball, and it is probable that steps looking to the formulating of even more extensive plans will be taken by the Board in the near future."

SEWERS.—See our Proposals Columns for information regarding sewer construction at the following places: La Salle, Ill ; Poughkeepsie, N. Y.; New York City ; Tiffin, O.; Rogers Park, Ill.; Boston, Mass.; Greensboro, N. C.; Key West, Fla.; Para, Brazil; Galion, O.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

FOREST CITY, PA.—There is some talk of erecting a bridge over the river at this place.

SOUTH ST. LOUIS, MO.—A pontoon bridge is proposed for South St. Louis, across the Mississippi, to cost $170,000, and have a draw 500 feet long.

ZANESVILLE, O.—T. C. Connar, County Surveyor, writes: "I have prepared plans for a bridge to be erected over the Muskingum River, at the north end of Fifth Street, this city, the cost of which will be from $104,000 to $108,000."

LEAVENWORTH, KAN.—The Leavenworth and Platte Bridge Company will substitute a pivot draw bridge over the Mississippi River in place of the pontoon bridge at this point.

EUREKA, CAL.—The following bids for bridge over Eel River at Alder Point were received by O. D. Stern, Clerk Board of Supervisors, July 15: San Francisco Bridge Company, San Francisco, combination, capacity 800 pounds, $31,780; California Bridge Company, San Francisco, combination, capacity 800 pounds, $35,900; Bay City Iron Works, San Francisco, combination deck, capacity 800 pounds, $37,610; Pacific Bridge Company, San Francisco, combination, capacity 800 pounds, $35,800; Randall, Hunt & Co., San Francisco, combination, capacity 800 pounds, $38,993; American Bridge and Building Company, San Francisco, combination, capacity 800 pounds, $33,600; Pittsburg Bridge Company, Indianapolis, wrought-iron bridge, capacity, 500 pounds, $28,780, superstructure only. Contract awarded to San Francisco Bridge Company at above figure. Bridge to be completed December 1, 1890.

BROWNSVILLE, TEX. — The Continental Bridge Company has been incorporated, with F. C. Roman, President, Enrique Viscaya, of Mexico, Vice-President, and J. A. Brown, Secretary, to build a railroad and wagon bridge across the Rio Grande River to Mexico. The capital stock is $1,000,000.

OTTAWA, ONT.—The New York *Star* of July 31 prints the following: "It is reported that the rival promoters of the Ottawa, Morrisburg and New York Railroad, and the Ottawa, Waddington and New York Railroad, have arrived at an agreement to combine their forces on the scheme to build a bridge across the St. Lawrence. The first-named company is willing to co-operate with any company to build the southern half of the proposed bridge and the line to Albany to give the required New York connection, and it is believed the latter company will agree to this plan."

COLUMBUS, O.—The third lot of bids for the superstructure of iron work on the proposed Rich Street bridge has been considered by the County Commissioners, and the contract awarded to the Columbus Bridge Company at $27,853. The Columbus Bridge Company was also awarded the contract for the iron work on the Fishinger Mill bridge and the Mound Street superstructure work at their bid, respectively, of $14,850 and $22,000.

JERSEY CITY, N. J.—The Delaware, Lackawanna and Western Railroad Company has decided to rebuild its long bridge over the Delaware River two miles below Portland. It will be a steel structure carrying two tracks. Work is to begin immediately, and it is expected that the new structure will cost about $300,000.

NASHVILLE, TENN.—The Nashville, Chattanoogo and St. Louis has submitted a proposition to the Charlotte Turnpike Company, looking to the construction of an iron bridge over the Nashville, Chattanooga and St. Louis tracks at the Charlotte crossing.

WHEELING, W. VA.—The following proposals for building the 158-foot span stone arch foot-bridge, over Wheeling Creek, at Main Street, have been received by the sub-committee of the City Council: Page, Carey & Co., New York City, $109,583.50; Hallock Bros., Rootstown, O., $107,985.47; S. Harrold & Campbell, Beaver Falls, Pa., $112,185.75; B. B. Harris, Greensburg, Ind., $127,802.75; J. LeDuke & Co., Berea, O., $132,274.10; Jutte, Stratton & Foley, Pittsburg, Pa., $139,941.02; Jolly Bros., Pittsburg, Pa., $144,299.50. The contract was awarded to Page, Carey & Co. Two of the bids were irregular, and were not considered. The bid of Hallock Bros. was withdrawn by the firm before the work was let.

Elmira, N. Y.—The Lake Street bridge in this city is to undergo extensive improvements. Alderman Cotton can furnish information.

New London, Conn.—Extensive improvements are to be made to the Niantic draw bridge.

Bridges.—See our Proposal Columns for information regarding bridge construction at the following places: Roanoke, Va.; Easley, S. C.; Toledo, Wash.; Montgomery, Ala.; Beeville, Tex.

NEW DEPOTS.

Brooklyn, N. Y.—Reports say that a mammoth railroad depot is to be built at Sixty-fifth Street; and that the New York and Sea Beach Railroad is behind the project. The Brooklyn and Brighton Beach and the Brooklyn and West End roads are, it is said, also interested in the plan, which contemplates a union depot.

Philadelphia, Pa.—Plans are being prepared by Wilson Brothers & Co., architects, for a large freight station at Camden for the Reading Railroad. The new station will be equipped with extensive sheds, platforms, and siding for 100 cars. A float ship wharf and transfer bridge will be built and a coal yard established.

STREET-WORK AND PAVING.

Buffalo, N. Y.—Paving contracts aggregating over $400,000 have been awarded to the Barber Asphalt Company, by the Common Council of this city.

St. Louis, Mo.—The Board of Public Improvements will soon decide on a date for awarding the contract to put down granitoid sidewalks on Pine Street; estimated cost, $8,000.

Flushing, L. I.—Thomas F. Tuohy & Co., of this place, were the lowest bidders for the contract for rebuilding the North Hempstead turnpike, their figure being $62,500. Thomas Willetts, of Roslyn, was the only other bidder and offered to do the work for $67,000, but since the bids were opened he withdrew his offer. The Town Board of North Hempstead will meet this week to award the contract.

Lexington, Ky.—All the principal streets of this city are to be paved with brick. Estimates are wanted for doing the work.

North Baltimore, O.—A small lot of macadamizing and curbing will shortly be done here. Address John P. Force, engineer in charge.

GAS AND ELECTRIC-LIGHTING.

Slatington, Pa.—This place is about to abandon the incandescent and substitute the arc lights for street illumination.

Lawrence, Mass.—The Committee on the Streets, of the Board of Aldermen, met recently to consider proposals for street lighting. Two bids were submitted, both of which were accepted, that of the Lawrence Gas Co., to furnish 70 or more 2,000 candle-power arc lights at $100 each per year, and of the Edison Illuminating Co., for 500 or more 20 candle-power incandescent lights at $1.00 each per night, to burn until midnight, and at least 150 of these to burn all night, at $3.04 each. A proposition by the former company to furnish 90 or more 1,200 candle-power lights of the divided arc system, at $85 per year, was not acted upon.

Hulings, W. Va.—It is probable that the Hulings Lumber Co. will establish an electric lighting plant at this place.

Laurel, Md.—This place is to have electric lights. Address John Chollar for particulars.

Beatrice, Neb.—The Beatrice Gas Company will soon want proposals for laying two miles of additional gas pipes.

San Francisco, Cal.—In this city bids for street lighting for the years 1891 and 1892 have been received as follows: San Francisco Gas Company, for lighting each gas lamp per night, 55 cents. California Electric Light Company, for each 16,000 candle-power mast, $4.40 per night; for each 2,000 candle-power lamp per night, 55 cents. The bids have been placed in the hands of the Lighting Committee.

Tecumseh, Mich.—The people of this place will have an electric lighting plant at a cost of $50,000.

Newark, N. J.—About four miles of additional gas mains will be laid at this place.

Oil City, Pa.—By authority of the City Council the Comptroller will soon advertise for bids for lighting this city with electric light for ten years, the plant to have a capacity of not less than 100 arc lights of 2,000 candle-power, and 1,000 incandescent lights at 16 candle-power each.

Batesville, Ark.—For important information regarding a projected electric lighting plant for this place, address J. W. Hamilton, as above.

Dawson, Ga.—It is probable that immediate steps will be taken towards establishing an electric lighting plant at this place.

Lansing, Mich.—The National Fuel Gas Company has been incorporated here with a capital stock of $500,000.

Birmingham, Ala. — The Birmingham Fuel, Gas and Heating Company has been incorporated here with a capital stock of $250,000. The incorporators are Lewis M. Parsons, J. M. Crowder, and others.

Tremont, Pa.—This place is to have an electric light plant.

Clinton, Mass.—Improvements are soon to be made to the plant of the Clinton Gas Light Company.

Dallas, Tex.—The Dallas Electric Company has been incorporated at this place, and will establish a lighting plant at an estimated cost of $300,000. Address J. P. Smith, as above.

Port Angeles, Wash.—An electric light company has been incorporated at this place and a plant is to be established at once; estimated expenditure, $20,000.

Fresno, Cal.—The officials of this place have granted a franchise to Robert Barton to erect and maintain for fifty years an electric light plant. Operations will begin at once.

Logan, Utah.—This place is to have electric lights.

Fort Worth, Tex.—The Citizens' Electric Light and Power Company has been incorporated here, with a capital stock of $20,000. Incorporators, Henry Wells, Harris Schulze and others.

Cleveland, Tenn.—Reports say that W. S. Beckner, of this place, desires to purchase an electric light plant.

Selma, Ala.—An incandescent electric lighting plant will be established at this place by the Selma Gas and Electric Light Company.

Electric Railways.—New electric railways will be established and improvements will be made to those already built at the following places: Little Rock, Ark.; Belleville, Ill.; Springfield, Mo.; Boston, Mass.; Oakland, Cal.; Tacoma, Wash.; Puyallup, Wash.; San Bernardino, Cal.; Colton, Cal.; Bellingham Bay, Wash.; Grand Rapids, Mich.; Rockland, Me.

The Contracting News Department of **THE ENGINEERING AND BUILDING RECORD** is edited with a view of giving space to no item that does not indicate where professional services or supplies may be needed in the near future, the prices bid for work or supplies, and the correction of false or misleading reports in some papers, that may subject readers to needless trouble and expense in going after something that does not exist.

BIDS OPENED.

Dallas, Tex.—Robert L. Jones, of this city, has been awarded the contract, at $276,967, for the construction of the new Court House. Red sandstone from Pecos, and white limestone from Honey Grove, all Texas material, will be used.

New York City.—At the meeting of the Dock Board July 31, the contract for supplying 15,000 cubic yards of cobblestones and 20,000 cubic yards of common stone for filling in bulkheads was awarded to Andrew A. Bowker, of New York City, his bids being 97 cents per cubic yard for the cobble and 67 cents for the common stone.

GOVERNMENT WORK.

Washington, D. C.—The following proposals for the work specified, were opened on the given dates by the Supervising Architect of the Treasury Department:

Pittsburg, Pa.—Iron stairways and iron work of interior finish for the United States Court House and Post Office at this place. Advertisement of June 28. Bidders: The Champion Iron Co., $31,880; Hough, Ketcham & Co., Iron Works, $56,222.39; The Samuel J. Creswell Iron Works, $60,994; Tacony Iron and Metal Co., $61,500; Poulson & Eger, $63,923; McHose & Lyon Co., $63,986; Fred J. Meyers M'f'g Co., $80,900; The Snead & Co., Iron Works, $81,868; L. M. Morris, $86,662.

Bedford, Mass.—General and trench excavation for the United States Post-Office building at this place, opened July 29. Advertisement of July 7. Bidders: Brownell & Markland, $1,705.20; Charles J. Place, $2,500.

Pittsburg, Pa.—Plumbing and gas piping for the United States Court House and Post-Office at this place, opened July 18. Advertisement of June 27. Bidders: Montgomery & Pattison, $33,500; Standard Plumbing Co., $34,000; Charles H. Humbert, $40,046.74; James Hay, $45,264; I K. Becker, $47,380; John M. Tate, $49,896.86.

INDUSTRIAL.

Geneva, N. Y.—On July 12 the New York Central Iron Works Company completed its organization by the election of the following officers: President, Wm. B. Dunning; Vice-President and Treasurer, O. J. Cammann Rose; Secretary and Manager, Edward H. Squires; Superintendent, Charles H. Huke. Mr. Squires, it will be noticed, retains the place held by him so many years.

Elizabeth, N. J.—The Singer Sewing Machine Company will make numerous improvements to their plant here, including the erection of additional buildings and putting in new machinery.

Long Island City.—At a joint meeting of the Boards of Supervisors of Kings and Queens Counties, held at this place on July 31, a committee was appointed to visit Chicago for the purpose of studying the tunnel under the Chicago River, with a view to the construction of a similar work under Newtown Creek.

PROPOSALS.

(Continued from page ii.)

JULY 26, 1890.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M. on the 19th day of August, 1890, for supplying and delivering at freight depot at place of designation, the Post Office lock boxes, lock drawers, locks, pulls, plates, etc., for U. S. PUBLIC BUILDINGS as may be ordered during the fiscal year ending June 30, 1891. Copies of the specification and any additional information may be had on application at this office. Each bid must be accompanied by a certified check for $100. The Department reserves the right to reject all bids received after the time fixed for opening the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be sealed and indorsed "Proposal for Lock Boxes, Lock Drawers, Lock, Pulls, Plates, etc., for U. S. Post Offices," and addressed to JAS. H. WINDRIM, Supervising Architect. 10

PROPOSALS FOR MILITARY SUPPLIES. Office of the Quartermaster, U. S. Military Academy, West Point, N. Y., July 9, 1890. Sealed proposals, in duplicate, subject to the usual conditions, will be received at this office until 12 o'clock, noon, on the 8th day of August, 1890, for Gas Coal, Anthracite Coal, Hardwood, Charcoal, Building Materials, Paints, Plumbing Materials, Gas and Steam Fittings, Pulleys, Belting, Arch Plates for Steam Boilers, Fire Brick, Fire Clay, Stationery, Printing Materials, Office Furniture, Brooms, Soap, Brushes, Range Parts, and other miscellaneous stores specified on schedules to be had upon application here. Preference will be given to articles of domestic production or manufacture, conditions of quality and price (including in the price of foreign productions or manufactures the duty thereon) being equal. Inclose proposals in envelope marked "Proposals for Military Supplies," and addressed to the undersigned, CHAS. W. WILLIAMS, Captain and A. Q. M., U. S. A. 9

SEWERS, Tiffin, O.—Proposals are wanted until August 16, for constructing about seven miles of sewers. Address P. J. Wilson, of the Street Committee, 126 Washington Street, as above.

STREET WORK, Clifton, O.—Proposals are wanted until August 16, for the improvement of numerous streets. Address S. G. Sterling, Village Clerk, as above.

WELLS, Carthage, O.—Proposals are wanted until August 7, for sinking two wells. Address Harry Simms, Secretary Board of Trustees, as above.

PROPOSALS.

PROPOSALS FOR THE ERECTION OF Buildings.—Office of the Quartermaster, U. S. Military Academy, West Point, N. Y., July 24, 1890.—Sealed proposals, in triplicate, subject to the usual conditions, will be received at this office until 12 o'clock, noon, on the 13th day of August, 1890, for the erection of ten sets of enlisted men's quarters and one Quartermaster's storehouse, as per plans and specifications to be seen at this office. Inclose proposals in envelope marked "Proposals for Erection of Buildings," and addressed to the undersigned, CHAS. W. WILLIAMS, Captain and A. Q. M., U. S. A. 10

JULY 31, 1890.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M., on the 26th day of August, 1890, for all the LABOR AND MATERIALS required for the marble work, etc. for the U. S. Court House and Post Office building at PITTSBURG, PA.,* in accordance with the drawings and specification, copies of which may be had on application at this office or the office of the Superintendent. Each bid must be accompanied by a certified check for $500. The Department will reject all bids received after the time fixed for opening the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be sealed and indorsed, "Proposal for the Marble Work for the U. S. Court House and Post Office building at Pittsburg, Pa.," and addressed to JAS. H. WINDRIM, Supervising Architect. 10

PAVING, Tiffin, O.—Proposals are wanted until September 10, for constructing about half a mile of brick paving. Address P. J. Wilson, of the Street Committee, 126 Washington Street, as above.

LIGHTING, Watkins, N. Y.—Proposals are wanted until August 5, for lighting the streets of this village by electricity. Address the Board of Trustees, as above.

BRIDGE, Easley, S. C.—Proposals are wanted until August 7, for rebuilding the bridge over George's Creek at this place. Address Elias Day, as above.

SEWERS, Greensboro, N. C.—Proposals are wanted until August 21, for constructing a portion of the proposed system of pipe sewers for this place. Address William M. Houston, Chairman Sewer Committee, as above.

FLAGGING, New York City.—Proposals are wanted until August 12, for flagging certain streets. Address the Department of Public Works, as above.

PAVING, Akron, O.—Proposals are wanted until August 23, for constructing one mile of brick paving. Address S. W. Parshall, City Engineer, as above.

BRIDGES, Johnstown, Pa.—Proposals are wanted until August 7, for the construction of four bridges. Address John Downey, City Engineer, as above.

PAVING AND SEWERS, Dennison, O.—Proposals are wanted, no date specified, for doing certain paving and constructing certain sewers. Address the City Clerk, as above.

BRIDGE, Beeville, Tex.—Proposals are wanted until August 22, for the construction of an iron bridge over the Medio River. Address the Town Clerk, as above.

STEAM HEATING, Toronto, Canada.—Proposals are wanted until August 6, for the steam heating and fire engines, pumps, tanks and piping in connection with the water supply for the Upper Canada College buildings. Address Stuckland & Symons, 18 Toronto Street, as above.

Building Intelligence.

We solicit from each and every one of our readers information relating to projected buildings in their locality, and should be glad to receive newspaper clippings and other items of interest.

DENVER, COL.—Broadway, bet 17th and 18th, interior finish in theater; cost, $90,000; o, W H Bush; a, L M Wood.

Ashland av bet Mary and Burt, br block; cost, $30,000; o, Wheeler & Brown; b, as above.

Penn av bet 18th and 19th, d'ble br dwell; cost, $7,000; o, I F O'Brien; a, Jas Murdock.

Cor 23d and Logan avs, s and br church; cost, $40,000; o, Swedish church; a, Barressen Bros.

Penn. av bet 7th and 8th avs, br terrace; cost, $36,000; o, Sam McClair; a, Huddart & Jocobsin.

Logan av bet 10th and 11th, stone dwell; cost, $30,000; o, A C Dake; a, Varian & Sterner.

Grant av cor 18th, stone dwell; cost, $30,000; o, S L Holzman; a, as above.

Penn. av bet 14th and 15th, stone terrace; cost, $70,000; o, C H Smith; a, as above.

15th cor Chestnut; br factory; cost, $8,000; o, John Winch; a, W G Riddock.

Franklin bet 38th and 39th, br terrace; cost, $7,600; o and a, Wm Noltie.

Gray bet Beagle and Fay, br dwell; cost, $7,000; o, J C Marshall; a, W S Campbell.

Montclair, br dwell; cost, $10,000; o, Mrs Pells; a, Varian & Sterner.

DETROIT, MICH.—N e cor 2d av and Ledyard st, s church; cost, $25,000; o, Central Church of Christ; a, Malcomson & Higginbotham; b, not let.

S e cor Randolph and Larned sts, 6-story br hotel; cost, $25,000; o, Capt S B Grummond; a and b, same as above.

S w cor St Aubin av and Canfield av, 3-story br parochial res; cost, $8,000; o, St Albertus R C Society; a, Peter Dederichs, Jr; b, not let.

N w Buchanan st and Wesson av, br church and rectory; cost, $19,000; o, St Francis R C Society; a, H Engelbert; b, not let.

187 Elizabeth st East, 3-story br asylum, cost, $12,000; o, House of Providence; a, G W Lloyd; b, A Chapoton, Jr.

492–98 Baker st, block 4 2-story br stores; cost, $16,000; o, J F Weber & Co, a and b, same as above.

GENEVA, ILL.—3-story br and st court house and jail; cost, $50,000; o, Kane County; a, F E Edbrooke & Co, Denver, Col; b, not let.

GRAND RAPIDS, MICH.—College av, nr Cherry, fire br, s and fr res; cost, $25,000; o, Mrs W S Hull, a, Mason & Rice, of Detroit; b, Campball & McNabb.

HOLYOKE, MASS.—Main st, 5-story 16 ten br block; cost, $36,000; o, A E Crosby; b, T St Martin & Son.

MERIDEN, CONN.—Center st, br factory bldg; cost, $7,700; o, The E Miller Co; a, H M Jones; b, not let.

MARSEILLES, ILL.—Two school buildings will be erected here at a cost of $20,000. Address A Smith, architect, as above.

MILWAUKEE, WIS.—Ogden & Astor sts, dwell; cost, $7,000; o, Ed Barber; a, Ferry & Clos; b, M Neff.

Lake av and Wyoming st, dwell; cost, $7,000; o, Albert Cunningham; a, James Douglas; b, T Prepenhager.

Mitchell st and 4th av, school-house; cost, $8,666; o, St Anthony Cong'n; a, H Messmer; b, Bentley & Strachota.

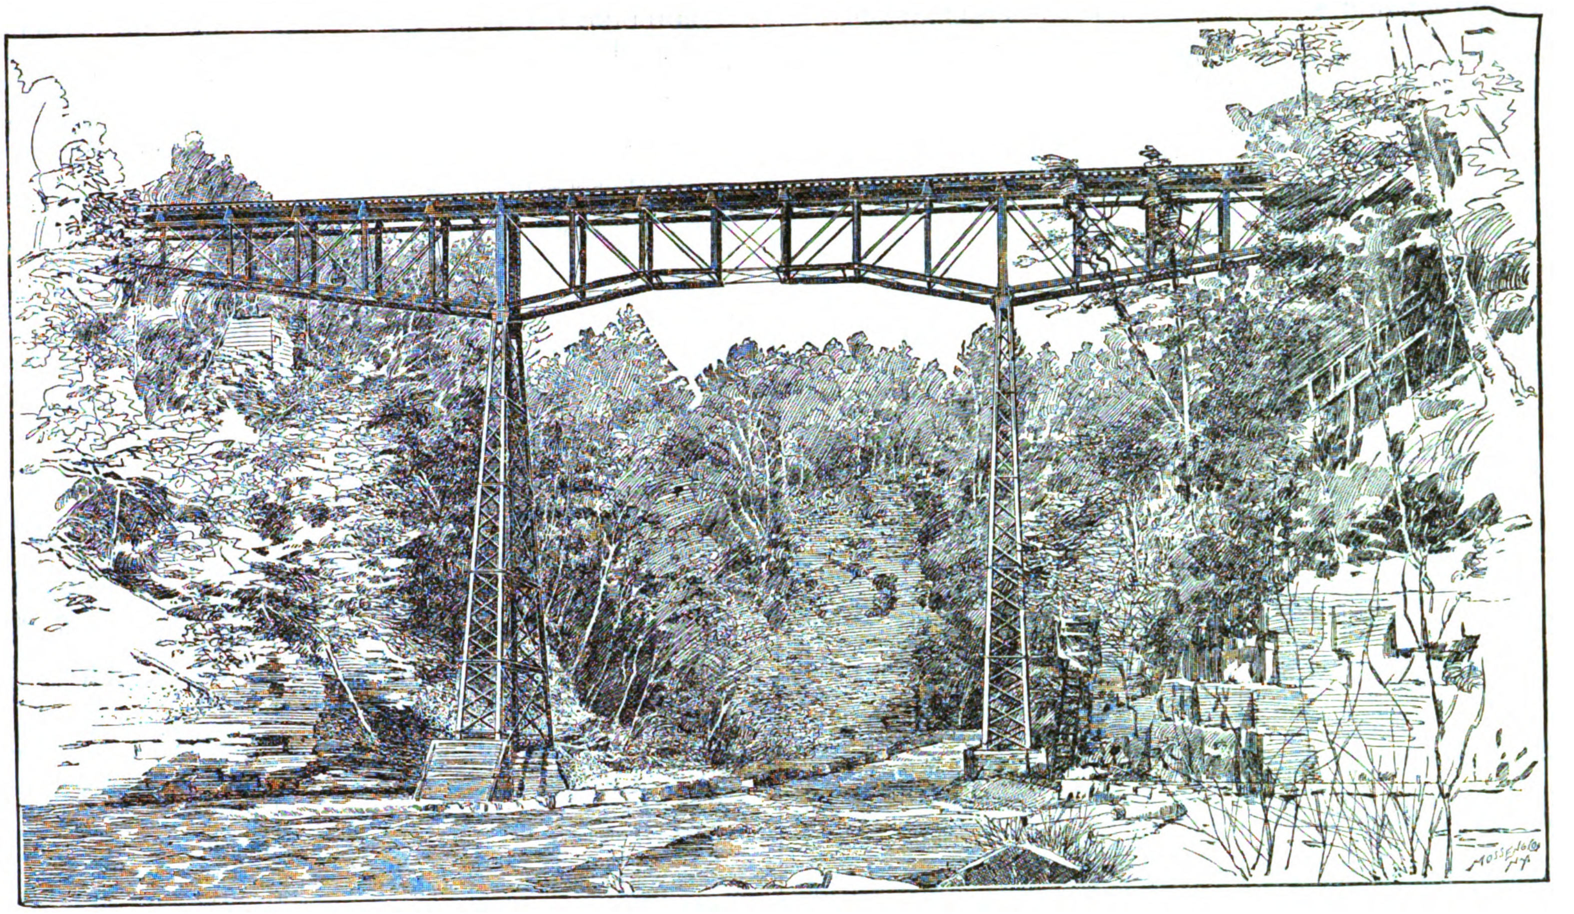
Greenfield av, convent; cost, $21,000; o, St. Vincent Society; a, E J Mit & Co; b, H Schlingsted.

MINNEAPOLIS, MINN.—Long & Keeys, architects, are making plans for an immense warehouse for storage purposes, to cost, it is said, $500,000. The parties interested are located in Chicago.

The recently burned Security warehouse will be rebuilt, at a cost of $50,000.

The permit for the new Y M C A bldg has been issued. The cost is $137,000. It will be of brick and stone, 5 stories high.

MADISON, WIS.—Alterations in the Brown block on S Pickney st, to cost $15,000, have been planned by Conover & Porter.



CANTILEVER BRIDGE,

DESIGNED AND BUILT BY

THE BERLIN IRON BRIDGE CO., EAST BERLIN, CONN.

FOR THE K. & A. C. R. R. CO., AT KEESEVILLE, N. Y.

BUILDING INTELLIGENCE.

PROVIDENCE, R. I.—Stinson av, fr dwell; o, R A Robertson, Jr; a, W E Chamberlain.

Westminster st, br and s banking bldg; cost, $100,000; o, R I Hospital Trust Co; a, R W Gilson; b, Darling Bros.

Alumni av, fr dwell; cost, 8,000; o, Thomas Chase; b, H W Goff.

PORTLAND, ORE.—Van Brunt & Howe, of Kansas City, have drawn plans for a union depot to be built at this place by the Northern Pacific Terminal Co. It will cost $1,000,000.

ST. PAUL, MINN.—Lee st, near Warsaw st, 2-story fr dwell; cost, $7,000; o, John Bergstrom.

E Congress st, near Ada st, 2-story br dwell; cost, $25,000; o, Peter Rothauser.

E 6th st, near Sibley, 2-story br store; cost, $8,000; o, L E Reed.

Victoria st, near Goodrich st, 2-story br and stone block; cost, $60,000; o, G H Schickler.

Work will soon be commenced on the wing to the new City Hospital. It will cost $50,000.

The Town and County Club will build a club house at the corner of Marshall av and Summit av boul, at a cost of $22,000.

ST. LOUIS, MO.—Pine st and Grand av, br hall; cost, $10,000; o, Marquette Club; b, Bryan Brady.

14th st and Sullivan av. br church; cost, $15,000; o, Salem Reformed Church; b. E Wind & Co.

Lafayette and Ohio avs, br store and dwell; cost, $9,600; o, W F Gebhardt; b, Chas Busch.

S w cor 9th and Angebrodt sts, br stable; cost, $7,000; o, H Gerke; b, Wm Kerksick.

15th and Locust sts, br store, cost, $23,000; o, L C Nelson; b, Cook & Casey.

DeKalb and Arsenal sts, br cooperage; cost, $9,700; o, Anheuser-Busch Brewing Association; b, Wm Reiwe & Son.

BUILDING INTELLIGENCE.

SAN ANTONIO, TEX.—Navarro st, office bldg; cost, $50,000; o, Alamo Fire Insurance Co; a, J R Gordon; b, not let.

SHEBOYGAN, MICH.—2-story br veneered school-house; cost, $8,000; o, Board of Education; a, F W Hollister; b, A B Troup.

WORCESTER, MASS. — Belmont st, fr church; cost, $7,000; o, Armenian Society; a, S C Earle; b, A E Bigelow.

Wachusett st, fr house; cost, $7.000; o, F E Williamson; a, Barker & Nourse; b, not let.

Water st, br factory; cost, $20,000; o, W H Hill; a, Fuller & Delano; b, A M Kelley.

Tainter st, br factory; cost, $15,000; o, S Forehand; a, E Boyden & Son; b, not let.

S Worcester st, fr dwell; cost, $7,000; o, A Thomas; a, J B Woodworth; b, F H Holland.

WALTHAM, MASS.—Prospect st, n w cor Highland st, 2-story br bus block; cost, $12,000; o, C H Bill; a, Samuel Patch; b, not let.

W s Moody st, nr Crescent, 3-story br block; plans not completed, but cellar commenced; o, Handy & Lincoln; a, O C Shepherd; b, not let.

Elm st, alterations on interior of theater; cost, $5,300; o, W D Bradstreet, manager; a, H W Hartwell.

WILKES BARRE, PA.—S Franklin sts, br dwell; cost, $8,000; o, Harry Stoddart; a, Kipp & Podmore; b, W H Pethica.

S Franklin st, br dwell; cost, $7,500; o, Wm Stoddart; a and b, as above.

BUILDINGS.—There is nothing over $7,000 in value to report at the following: Geneva, N. Y.; Harrisburg, Pa.; Little Rock, Ark.; Ogdensburg, N. Y.; Lancaster, Pa.; Columbus, O.; Reading, Pa.; Springfield, Mass.; Canton, O.; Baltimore, Md.; Pottsville, Pa.; Saginaw, Mich.; Fitchburg, Pa.; York, Pa.; Dayton, O.; Oil City, Pa.; Springfield, O.; Zanesville, O.; Findlay, O.; Topeka, Kan.; Akron, O.

Some Details of Water-Works Construction.

By W. R. BILLINGS, Superintendent of Water-Works at Taunton, Mass.

WITH ILLUSTRATIONS FROM SKETCHES BY THE AUTHOR.

INTRODUCTORY NOTE.

Some questions addressed to the Editor of *The Engineering and Building Record and The Sanitary Engineer* by persons in the employ of new water-works indicated that a short series of practical articles on the Details of Constructing a Water-Works Plant would be of value; and, at the suggestion of the Editor, the preparation of these papers was undertaken for the columns of that journal. The task has been an easy and agreeable one, and now, in a more convenient form than is afforded by the columns of the paper, these notes of actual experience are offered to the water-works fraternity, with the belief that they may be of assistance to beginners and of some interest to all.

TABLE OF CONTENTS.

CHAPTER I.—MAIN PIPES—

Materials — Cast-Iron — Cement-Lined Wrought Iron — Salt-Glazed Clay — Thickness of Sheet Metal—Methods of Lining — List of Tools — Tool-Box — Derrick — Calking Tools — Furnace — Transportation—Handling Pipe—Cost of Carting—Distributing Pipe.

CHAPTER II.—FIELD WORK—

Engineering or None — Pipe Plans — Special Pipe—Laying out a Line—Width and Depth of Trench—Time-Keeping Book—Disposition of Dirt—Tunneling —Sheet Piling.

CHAPTER III.—TRENCHING AND PIPE-LAYING—

Caving—Tunneling—Bell-Holes—Stony Trenches—Feathers and Wedges—Blasting—Rocks and Water—Laying Cast-Iron Pipe—Derrick Gang—Handling the Derrick—Skids—Obstructions Left in Pipes —Laying Pipe in Quicksand—Cutting Pipe.

CHAPTER IV. — PIPE-LAYING AND JOINT-MAKING—

Laying Cement-Lined Pipe—' Mud" Bell and Spigot—Yarn—Lead—Jointers —Roll—Calking—Strength of Joints—Quantity of Lead.

CHAPTER V.—HYDRANTS, GATES, AND SPECIALS—

CHAPTER VI.—SERVICE-PIPES—

Definition—Materials—Lead vs. Wrought Iron—Tapping Mains for Services—Different Joints — Compression Union — Cup.

CHAPTER VII.—SERVICE-PIPES AND METERS—

Wiped Joints and Cup-Joints—The Lawrence Air-Pump—Wire-drawn Solder—Weight of Lead Service-Pipe—Tapping Wrought-Iron Mains—Service-Boxes—Meters.

HANDSOMELY BOUND IN CLOTH.

Sent (post paid) on receipt of $2.00 Address,

BOOK DEPARTMENT, THE ENGINEERING AND BUILDING RECORD,
277 Pearl Street, New York.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22. NUMBER 10. | PUBLISHED EVERY SATURDAY. 277 PEARL ST., NEW YORK.

NEW YORK, AUGUST 9, 1890.
LONDON, AUGUST 23, 1890.

SINGLE COPIES, TEN CENTS. Subscription, $4.00 per year in advance, post paid. } IN AMERICA.
SINGLE COPIES SIXPENCE. Subscription, 20*s*. per annum in advance, post paid. } IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at 277 Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.

20*s*. in GREAT BRITAIN. Other Foreign Countries $5.

Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & CO., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $5; China, Japan, Sandwich Islands, Mexico and Cuba, $5; South America, $5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

FIREPROOF CONSTRUCTION.

MR. EDWARD ATKINSON's letter on the recent Western Union Building fire, at New York, extracts from which are published elsewhere in this issue, furnishes decidedly instructive reading and deserves every architect's attention. The points to which he refers as being frequently overlooked in the construction of what are called fireproof buildings are well taken, and illustrate, in a striking manner, the strange inconsistencies which every one interested in the subject must have noticed at some time or other. Where buildings are erected with the view to making them as nearly safe as possible from destruction by fire there is frequently no excuse for filling them with a mass of such highly combustible substances as is found in the shape of many decorative materials and articles of furniture. Experience has shown that whatever safety is secured by the main features of construction of such buildings can be completely neutralized by their inflammable contents.

A matter of special interest, to which Mr. Atkinson refers, is the profit to be derived from investigations of the cause and course of every considerable fire as conducted by the Factory Mutual Insurance Companies. Experience, in this as in all other things, teaches valuable lessons, and such investigations, if conducted generally and conscientiously, would do much to advance the science of fireproof building.

STORAGE BATTERY SYSTEMS FOR STREET CAR PROPULSION.

CONSIDERING the lively underground electric wire agitation which has been going on in the City of New York for the last few years, the proposed electric street car systems in Brooklyn, just across the river, cannot fail to attract attention. The overhead wire system is there proposed, and the three railroad companies contemplating it have their plans all made, and are only waiting for official consent to begin work.

However much the displacing of horses for street car propulsion is to be commended, it cannot be maintained that the system which will probably go into effect in Brooklyn is in any sense advisable or an improvement. The dangers of overhead electric wires, carrying high tension electric currents, which must, of necessity, be employed for street car work, have been demonstrated in striking and unfortunate ways on numerous occasions. Only a week or two ago two horses were instantly killed at Boston by coming in contact with a broken guard wire dangling from the overhead structure of an electric car line. The system there is essentially the same as that contemplated in Brooklyn. To avoid dangers such as this there is only one way which would prove practically successful, and that is to prohibit such overhead installations. They are not entitled to a place in any community, least of all in a crowded one, and they have nothing to favorably commend them that cannot be claimed for some other means of propulsion, except possibly cheapness of construction, and consequently profitable working. In this, however, the public has no interest. The street car companies alone reap the benefits.

What is wanted is an efficient and a safe substitute for horse power, and this is not offered by the overhead electric system. Even cable traction is a much more desirable means of locomotion though it, too, is not without objectionable features. The whole solution of the street car problem, as we pointed out on a former occasion, is found in the practical application of a storage battery system. There is, of course, some consideration to be given to the matter of cost. This has always been figured so high as to be fatal to a successful storage battery enterprise, and has almost invariably been brought up as the stumbling block supposed to lie in the way of its realization. The appended figures are, therefore, interesting, being represented as the results of calculation made some time ago for the Fourth Avenue street car line in New York, on which the Julien storage battery is used:

	Electric.	Horse.	Cable.
Cost of cars	1	.54	.81
Cost of motive power	1	1.45	1.06
Construction of roadway	1	.53	2.09
Depreciation and repairs	1	1.47	2.04
Operating expenses	1	3.38	1.71
Total	5	7.37	7.71
Average	1	1.47	1.55

We do not know just how closely these figures correspond with those since found in every-day work. And it is, of course, not to be assumed that each of these items is of equal importance, or, in other words, that each represents 20 per cent. of the total annual expense; but even if an appreciable percentage be added to the given cost of the electric traction, it is probable that there would still be a margin for profit as compared with horse and cable power. In any event, the entire absence of overhead and underground work in the storage battery system is an advantage of great importance. On the Fourth Avenue line in New York, the system has been in use for more than a year, and if success there be attained, as it seems to have been, there is no reason why it should fail on other lines. Judging from present indications the system is the only one which gives reasonable assurance of safety to life and property.

VACUUM STEAM PUMPS.

THE question of economy in the use of steam pumps involves several considerations, such as the particular kind of work to be done, the first cost of the pump, cost of running and maintenance, the length of time for which the pump is to be used, and several others. It is not steam or coal consumption alone that is to be taken as the measure of economy of a pump, but the result of a careful comparison of the relative values of steam and of simplicity of construction, and it thus frequently becomes an interesting problem to determine which of these two values is properly entitled to the greater share of attention. If we take the comparatively simple case of flooded excavations to be pumped dry, the choice of a pump to do the work is easily governed. A cheap pump, even though comparatively wasteful in the use of steam, will generally be selected and will successfully meet the requirements of the service.

It is natural that under these circumstances the different forms of pumps of the vacuum class, such as, for example, the pulsometer, the pulsator, the aqua-thruster, the Simplex pump, and others are coming into more prominence, though the recent advances made in the design and construction of such pumps may be held to partially account for their growing popularity. All these pumps have the obvious advantages of simplicity and low cost. Of course, as compared with some other forms of pumps, their figures for steam consumption are often, in fact, generally, pretty high. Still, the demand for simple pumping machinery, capable of handling large quantities of water will keep them in favor, and as, in the course of time, means will probably be found to make them more economical without sacrificing their simplicity, better performances may be expected.

It has been well suggested that a partial remedy for the great waste of steam in these pumps may be found in the adoption of a lining for their steam and water chambers, to consist of a metal having a comparatively low specific heat, as, for example, lead, or of some good non-conducting substance. Taking, say, lead as the lining material, the following figures, which we find in some miscellaneous data on the subject, show very strikingly what degree of saving may be effected by it. We will assume that the pump chambers are alternately heated and cooled through a range of temperature of 200° Fahr., and also that sufficient time is allowed to elapse between each stroke or discharge for the whole of the metal to pass through this range of temperature. The specific heat of lead may be taken as 0.0314, that of water being 1, while that of iron is about 0.12. These figures represent the respective losses caused by condensation proper to lead and cast iron. For every 314 pounds of steam condensed by the lead, 1,200 pounds will be condensed by the iron, showing that by the use of the former instead of the latter metal about 74 per cent. of the steam wasted could be saved. This is an important item, and it seems strange that builders of this type of pump do not appear to have recognized it as such and, so far as we are aware, have not yet taken it into account. In a great measure this prevailing disregard of economical considerations may be ascribed to the absence of reliable test figures, and experimental investigation of the performances of such pumps may, therefore, be appropriately urged. The information which it would yield might lead to changes in construction from which appreciable benefits could be realized.

WORKING BURMESE OIL WELLS.

DR. NOETLING, of the Indian Geological Survey, in his report on the petroleum deposits of Burmah, gives an interesting description of the native method of digging the wells. As soon as a native has made up his mind where he is going to have a new well, the workmen, usually four in number, begin to dig a square shaft, the sides of which measure between 4 feet and 4 feet 6 inches. Over this pit a cross beam, supported on stanchions at either side, is placed, in the center of which is a small wooden drum, or cylinder, which, with its axis, is made of a single piece of wood, the latter runing on coarse fork-shaped supports. The leather rope used in hauling up the oil passes over the drum, and on it is fastened the workman who is going to be lowered down, as well as the common earthenware pot in which the oil is drawn up. If possible, the well is so placed that the men or women drawing the rope walk down an inclined plane along the slope of a hill. The tools employed in digging are quite primitive, and can only be used in soft strata. Timber is used to support the walls of the shaft, and the latter is lined with wood. This wooden wall has considerable strength, but it has to be carefully watched lest it should give way.

The workmen are lowered in an ingenious way. The man sits on two slings formed of strong rope running between his legs and knotted over his left shoulder. To prevent sliding, a thin rope runs down from the knot, across the breast, underneath the right shoulder to the back, where it is fastened to the rope forming the slings. A second rope for the same purpose is fastened round the hips. On account of the explosive gas filling the shaft no light can be taken down; the workman, therefore, ties up his eyes previously to descending, so as to enable him to see during the short time he is in the well, otherwise it would take him longer to accustom his eyes to the darkness than he is able to stay down, on account of the gas which renders breathing difficult. The data obtained by Dr. Noetling as to the time occupied in the ascent and descent, and the period during which the laborer can remain below, show that not 25 per cent. of the total working time is really spent in extracting the oil. Two hundred and ninety seconds is the longest time any man, however strong, can remain below without becoming unconscious, while in some he can only remain 60 seconds. With increasing depths the difficulties in obtaining the oil after the Burmese methods become insuperable. Hence the limit is 310 feet, and the workers object to more than 250 feet.

The drawing up of the oil is as primitive as everything else. The rope is fastened round the neck of the ball-shaped pot, and, being lowered, is allowed to fill by sinking in the oil below. The oil thus raised is poured into another pot of the same shape, but much larger, and twelve of these are packed on each country cart.

ARCH WORK IN EARTHQUAKE COUNTRIES.

IN a paper entitled "Building in Earthquake Countries," read before the British Institution of Civil Engineers a short time ago, John Milne pointed out that while an ordinary arch is undoubtedly stable for vertically applied forces, it is most unstable for horizontal stresses. Arch work has so often been the cause of ruin, when shaken by an earthquake, that in Italy and Manilla special rules have been drawn up respecting such structures. Thus in Manilla intersecting vaults are not allowed, and ordinary vaults are only permissible when strengthened in a particular manner by iron. In Liguria vaults can only be used in cellars, but even there the rise must be at least one-third of the span. The law of Norcia also only permits the use of arch work in cellars, and the thickness and method of construction is defined. In Ischia arch work with a rise of one-third of the span, and with a thickness of 0.25 meter (0.82 foot) at the crown, may be used, but only in cellars.

Speaking generally, the use of arch work above ground has been prohibited, and if it has existed after an earthquake, all governments who have paid attention to building have ordered its removal. Underground its use is permitted, provided the arches are not too flat. This, however, only indicates that the motion beneath the surface is too small to destroy even a bad form of structure, and therefore such a form, if it be underground, is al-allowable.

There are instances where arch work in Tôkiô has been cracked by exceedingly slight earthquakes. If, for architectural reasons, it is a necessity that arches should exist, they should not be too flat; they should have a specified thickness, be protected by an iron or a wooden beam, and curve into the abutments. The Ligurian regulations provide that above windows there shall be two iron bars.

ON July 26, Judge Blodgett of the Circuit Court of the United States for the Northern District of Illinois, gave judgment in favor of the American Road Machine Company, of Kennett Square, Pa., in the suit brought August 16, 1888, against Goulds & Austin, now F. C. Austin Manufacturing Company, for patent infringement.

ACCORDING to the latest accounts concerning the Cincinnati, O., water-works, the situation is now much brighter than for a month past. Nothing in the way of permanent improvement, however, will be available for about two years, so it is stated. The present temporary arrangement works in a reasonably satisfactory manner.

SEVENTEENTH ANNUAL REPORT OF THE BOARD OF WATER COMMISSIONERS OF THE CITY OF PORT HURON [Mich.]; April 1, 1890; pp. 45.

UNEQUAL TEMPERATURE OF WATER IN A BOILER.

HENRY LEE, in his recent presidential address before the Manchester (England) Steam Users' Association, said:

"It is very generally known that in getting up steam in a boiler the temperature at the top of the water is very much higher than at the bottom, and it was thought that it would be of interest to take a series of observations from various boilers in work to ascertain what the difference in temperature amounted to, and what was the effect of conical water pipes or cross water pipes in promoting circulation and reducing this inequality of temperature.

"For this purpose a series of observations was taken at the mills of Messrs. Richard Haworth & Co., Salford, and Messrs. Sir Elkanah Armitage & Sons, limited, Pendleton, as well as at the works of Messrs. Beyer, Peacock & Co., limited, Gorton, each of whom kindly placed one or more of their boilers at the disposal of the Association for the purpose of the experiments. The report thereon has been drawn up.

"Under these circumstances I will not anticipate the report further than to make the following brief extracts:

"'When the water at the bottom of the boiler was at a temperature of 212 degrees only, the steam at the top of the boiler had risen in three cases to above 70 pounds pressure, and in two cases to above 80 pounds, while in one case as great a difference in temperature was observed as 236 degrees.' The report goes on to show that 'the inequality between the temperature of the water at the top and at the bottom when getting up steam is practically the same whether in a Lancanshire boiler with four cross water pipes in each flue tube, or in a Lancashire boiler without any cross water pipes at all, or in a Galloway boiler with 33 conical water pipes and two pockets, or with 30 conical water pipes and two pockets.' From this the conclusion is drawn 'that neither conical water pipes nor cross water pipes are as efficient in promoting the circulation of the water throughout the boiler as the public has generally supposed.'"

OBITUARY.

WILLIAM H. ADAMS, who many years ago was one of the foremost contractors in New York, and who afterward went to Washington, D. C., died in Elizabeth on the 4th inst., aged 58 years. Mr. Adams contracted malaria in Washington, and his health failing he came back to Elizabeth.

ALEXANDER CAMERON, a prominent architect for the past 30 years, of St. Louis, Mo., died after a brief illness, August 3. He was born in Halifax, Nova Scotia, in 1829, and began the practice of his profession at the age of 21. From 1849 until 1859, he lived in Rhode Island, and became a resident of St. Louis the following year. Among the most important buildings constructed by him was the St. Louis U. S. Custom House.

PERSONAL.

S. C. MACKAYE, Superintendent of Repairs of Water-Works in Rochester, N. Y., has been succeeded by Daniel O'Neil.

LOUIS GRANER has been reappointed City Engineer of Belleville, Ill., having already served the same city 17 years in this capacity.

OTTO WILHELM, architect, of St. Louis, Mo., leaves this week for Monterey, Mexico, to arrange for building a $160,000 stone brewery there for Jacob Schneider, of the same city, who accompanies him.

GEORGE R. BURNETT, C. E., was recently elected President of the Board of Public Improvements, St. Louis, Mo., Colonel Henry Flad, C. E., the former President, having been appointed a member of the Mississippi River Commission.

J. NELSON TUBBS, for many years Chief Engineer of the Rochester, N. Y., Water-Works, has resigned that position, and George W. Rafter, Assistant Engineer in charge of additional water supply, has been made Acting Chief Engineer.

THE consulting engineers, F. P. Stearns, of Boston, and Samuel M. Gray, of Providence, have made their report on the plans for the proposed sewerage system for Orange. They approve in the main the plans prepared by Carroll Ph. Bassett, the Engineer for Orange, but make many recommendations which will largely add to the cost of the work.

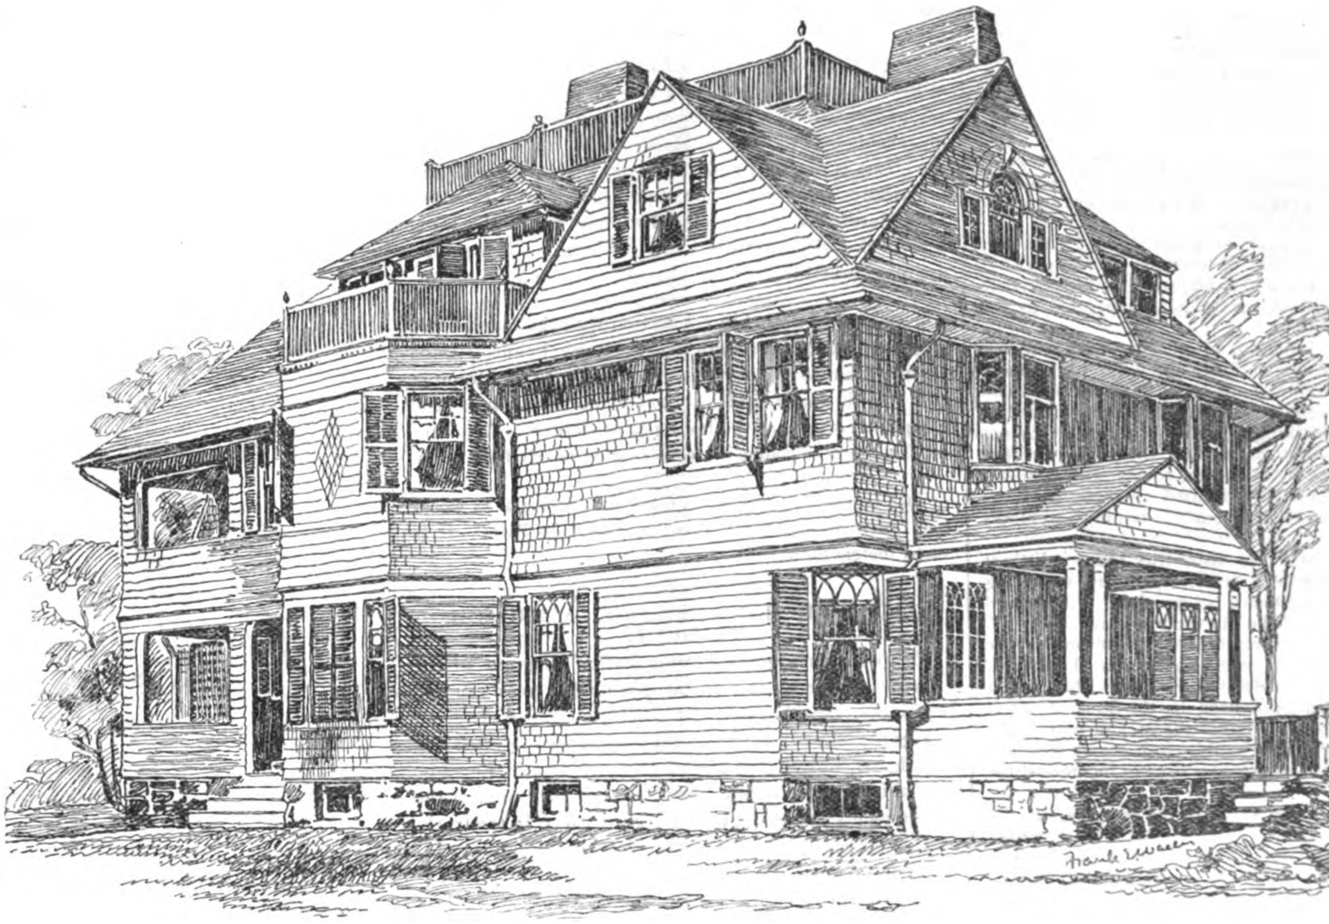
ENGINEERING SOCIETIES.

F. W. CAPPELEN, Secretary and Treasurer of the Engineers' Club of Minneapolis, Minn., writes, under date of July 30, that the old society of Civil Engineers of Minneapolis was disbanded and reorganized May 7, under the above name, with twenty-two charter members. Through the kindness of the Board on Public Library, the club has permission to hold its meetings in the public library. The Librarian of the public library, Mr. Putman, has offered to subscribe for any technical periodical the club may desire, both American and foreign, and will also buy any desirable works on engineering topics the club or individual members may ask for, and put them on file for general use in the library.

The club has had two well attended meetings under the new management. Papers were read on "Ventilation of Public School Buildings" and "Efflorescence on Brick." The club will make some experiments in regard to the two above mentioned subjects, and hopes to be able to publish these papers in an interesting and complete form this fall. At present everything points to a bright active future.

The present officers of the club are: Wm. A. Pike, President; Wm. de la Barre, Vice-President; F. W. Cappelen, Secretary and Treasurer; W. W. Redfield, Librarian; Andrew Rinker, member Board of Managers of Association of Engineering Societies.



HOUSE AT ORANGE, N. J.—E. T. HAPGOOD, ARCHITECT.

SECRETARY BOGART, of the American Society of Civil Engineers, announces the following meetings, papers and discussions: Meeting of September 3.—Paper on "Notes on a Mountain Slide," by William G. Curtis, M. Am. Soc. C. E. Meeting of September 17.—Discussion on paper by W. Barclay Parsons, M. Am. Soc. C. E., on "Railways in Mexico," by Max E. Schmidt, M. Am. Soc. C. E. Discussion on Paper by F. W. Watkins, M. Am. Soc. C. E., on "Tunnel Surveying on Division No. 6, New Croton Aqueduct," by O. F. Nichols, M. Am. Soc. C. E.

SECRETARY HUTTON, of the American Society of Mechanical Engineers, has issued a circular, specially intended for the newly elected members, inviting them to make use of the house and professional library of the society at 12 West Thirty-first Street, New York. The library was inaugurated at the beginning of the Society's existence by a system of exchange of its transactions with the leading journals and with sister societies at home and abroad. Sets of such society transactions and files of the journals, both current and former issues, will be found on its shelves. In addition to this department of the library, in 1884 a fund was started and is still maintained for the formation of a reference library of engineering. This fund has been judiciously expended for the purchase of standard and recent works, and this department is regularly added to both by purchase and by gift from interested members and others.

The society's house, beside a home for its growing library, is intended also to be a professional center for the use of its members while in New York. Private rooms can be put at the service of members for conferences, and drawing-room facilities can be provided if any one should want to use them for a short time.

LETTER FROM ENGLAND.

(Regular Correspondence.)

LONDON, July 25, 1890.

THE Plumbers' Company is to be congratulated on the evidence that it is beginning to feel its footing. The long disuse of its powers and influence had resulted in the said influence becoming an unknown quantity; it was a matter of congratulation, therefore, in 1886 when they, under pressure of certain leading plumbers throughout the kingdom, inaugurated the system of registration. It has previously been urged in the columns of THE ENGINEERING AND BUILDING RECORD that, inasmuch as this registration is optional, there is no power to prevent an unregistered plumber calling himself a registered plumber, and that there is no punishment for scandalous and "botch" plumbing. It is necessary and, indeed, incumbent upon the Plumbers' Company to get legislation enabling them to prevent uncertificated men from calling themselves registered plumbers, and, further, and more particularly, to mete out punishment for scandalous and dangerous work. At a public meeting held in the Town Hall, Kensington, on July 23, when the Hon. and Rev. Car Glyn, the Vicar of the Parish of Kensington, presided, there were present, among others, the Marquis of Lorne, Mr. W. H. Bishop, Master of the Plumbers' Company, Sir Algernon Borthwick, Dr. Farquharson, M. P., Mr. Leng, M. P., and Capt. James, Chairman of the Sanitary Committee of the London County Council. It was moved by Mr. Bishop that the report of the Court of Plumbers should be adopted. This report stated that the Court had been urged to apply for statutory powers to consolidate and enforce the registration system, and to obtain the necessary power for punishing in the case of defective work on the part of registered plumbers; further, to render it penal for people falsely to represent themselves as sanitary plumbers. Sir Algernon Borthwick seconded the adoption, stating as a matter of personal knowledge that the Local Government Board were most willing to promote anything for the furtherance of the objects of the Plumbers' Company. The Marquis of Lorne supported the motion, holding that the Company was justifiably putting forward a very drastic programme. The Plumbers' Company has gone so far that it will be a great pity if it will not be able to get the compulsory powers of registration and punishment for bad work, which alone will safe-guard it in its endeavors to do justice to the public.

The fact that a hopper dredger, "The Manchester," constructed by Messrs. Simons & Co., of Renfrew, has just been launched for service on the Manchester Ship Canal is indicative of the progress and near completion of the work. The special duty called for has caused Messrs. Simons to introduce new features into the vessel. The stern is forked allowing the ladder to work between to enable the vessel to be handled with greater facility. She is steered by three large rudders, one of which is situated at the bow. The buckets will dredge out 850 tons in one hour, and provision is made for dredging at a depth of 35 feet. The propelling power is given by four screws, situated, two each, at the bow and the stern.

Trouble of subsidence of the ground in the salt district is again in evidence, and inasmuch as there is now a salt union and a consolidation of the various interests in that industry, it would seem to simplify the matter of legislation. Appeal has been made to the Local Government Board for the appointment of a Royal Commission to go into the question of this subsidence, but the President has written, pointing out that a Royal Commission could be of very little service in the matter, the principal method of dealing with the question being by legislation.

The question of the purification of the Irwell, of course, presented itself when the Manchester Ship Canal was designed, that stream being one of the chief tributaries absorbed into the canal. With this view the drainage of Pendleton, a suburb of Manchester, which was formerly discharged in its crude state into the river, has been reconstructed, the engineers in the first instance being Mr. Vawser, and at his death Mr. T. S. McCalhun, A. M. I. C. E. The sewage is precipitated in four tanks under the International Water & Sewage Purification Company's system. The sludge is then treated by filter-beds and the effluent passed into the Irwell.

FIREPROOF CONSTRUCTION.

REFERRING to the recent Western Union building fire at New York, Edward Atkinson, President of the Boston Manufacturers' Mutual Fire Insurance Company, addressed an interesting letter on fireproof construction to the New York *Evening Post.* From this we extract the following:

> The points which are customarily overlooked or not considered in the construction and occupancy of what are called fireproof buildings are:
>
> *First.*—The liability to the very rapid destruction even of incombustible materials when subjected to the heat of a fire which is consuming the combustible contents.
>
> *Second.*—It is very commonly assumed that because most of the materials which are used in the construction of the building are incombustible, it may be entirely safe to make use of combustible material in the finish of the building itself, and to face the wall with moldings, dados, etc., generally varnished woodwork from which a great deal of heat may be suddenly generated, varnish being especially hazardous.
>
> *Third.*—It seems never to occur to owners or occupants that private fire apparatus cannot be effectively made use of without a thoroughly organized fire department or under the direction of well drilled men.
>
> The most complete destruction about which I have ever known, either from personal observation or hearsay, has occurred in buildings made of brick, stone and iron, where the iron has been exposed to the heat generated by the combustion of the contents.
>
> In respect to many buildings of otherwise excellent construction, the whole expenditure intended to promote safety has been lost by finishing around the windows and doorways with varnished woodwork; by placing varnished wooden dadoes or sheathing against solid walls; by not giving proper attention to cutting off the passage of fire from floor to floor, and by filling the rooms with combustible furniture sufficient when ignited to cause such expansion, torsion or flexure as to tear the building to pieces without burning it.
>
> With respect to private fire apparatus there is little if any which is of use unless it be self operating, excepting in factories or other premises where there is a trained private fire department, drilled in the use of it.
>
> From what I have learned of the conditions of the Western Union Building, it would appear that the shell of the building had been well devised for safety, but that a great deal of wood had been used in the finish where it was entirely out of place, and that the greater part of the furniture had been of a combustible sort, where it would have been far better and safer had it been of incombustible material.
>
> The accounts of the fire speak of the spread upon the "switchboards," and from "table to table" on which instruments had been placed. The difficulty of choosing incombustible material on account of electric conductivity is admitted, yet there are very many materials which are perfectly suitable for such service that are not combustible or ignitable.
>
> The private hose within the building is said to have been rotten, as it usually is when not under the care of the private fire department well trained in its use. The passage of fire from floor to floor was wholly unobstructed; a useless exposure in such a building in which the only open way should have been the elevator shaft. There were no roof hydrants or other appliances by which the building could have been flooded from above, and finally, there were no automatic sprinklers. There are some admitted difficulties in placing automatic sprinklers for the protection of buildings to which high tension electric currents are admitted, lest the water itself should make cross arcs on which the high-tension current of electricity might be spread. On this point we have as yet no experience, as all the electric apparatus in our risks has been so carefully put up and is so constantly guarded that we have never met a loss from an electric current, except those which are generated in the clouds during thunder storms. There were no high-tension currents in this service in the Western Union Building, if I am rightly informed; therefore an equipment with automatic sprinklers in the electric department would doubtless have saved the entire loss.
>
> One of the most useful functions of the officers of the Factory Mutual Insurance Companies is to investigate the cause and course of every considerable fire which comes under their notice, even if they have no policy out upon the risk, and then to review their own risks in order to see where the same danger may exist which has caused the fire under consideration, and to take measures to avoid that danger or to guard against it.
>
> I can hardly imagine a method which would be likely to save as much property from destruction as a combination of property owners in the city of New York, who should select and employ the most competent person or persons whom they could find, at whatever price might be required to secure competent services, to keep their buildings under constant inspection, to study every fire, and to advise owners how to adopt suitable safeguards on the basis of experience. Such private inspectors should have no interest in any insurance company or in any of the property under their supervision. If a few owners would combine and hire one such competent man for a single year I think they would be astonished and shocked at the dangers which they now tolerate from mere ignorance of the hazard which can yet be guarded against at very small expense. Sometimes the danger is due to indifference rather than to ignorance.

IT is thought likely that a serious brick famine will result in New York and Brooklyn from the boycott of the brick manufactured by O'Brien & Vaughey, King & Lynch, Avery & Mackay and Silas Travers, the four firms at Verplanck's Point, by the boards of walking delegates of New York and Brooklyn, and the resolution of the Brick Manufacturers' Association of New York and New Jersey, not to continue shipping bricks to these cities until the boycott is raised on the products of these four firms, who are members of the Manufacturers' Association. The Building Material Exchange has appointed a committee to try to secure a settlement of the trouble.

EXPERIMENTS by Prof. J. E. Denton, of Stevens Institute, Hoboken, N. J., have shown that when a steam jet is discharging freely into air from a nozzle, if a gap is observable between the visible cloud and the nozzle, then the steam is practically dry, and may also be considered practically dry even if the vapor is very faintly visible; but immediately it becomes distinctly white the water present has risen to from 1 to 2 per cent. These facts are most valuable.

THE longest tunnel in connection with the Manchester, England, water-works scheme—the Raise Tunnel—which extends from near Townhead, Grasmere, to the straining well at Thirlmere, and is 5,225 yards long, has been completed, so far as the boring is concerned. The tunnel has been in course of construction nearly four years.

THE largest barometer yet made has been put in working order in the Saint Jacques Tower in Paris. It is 12.65 meters high.

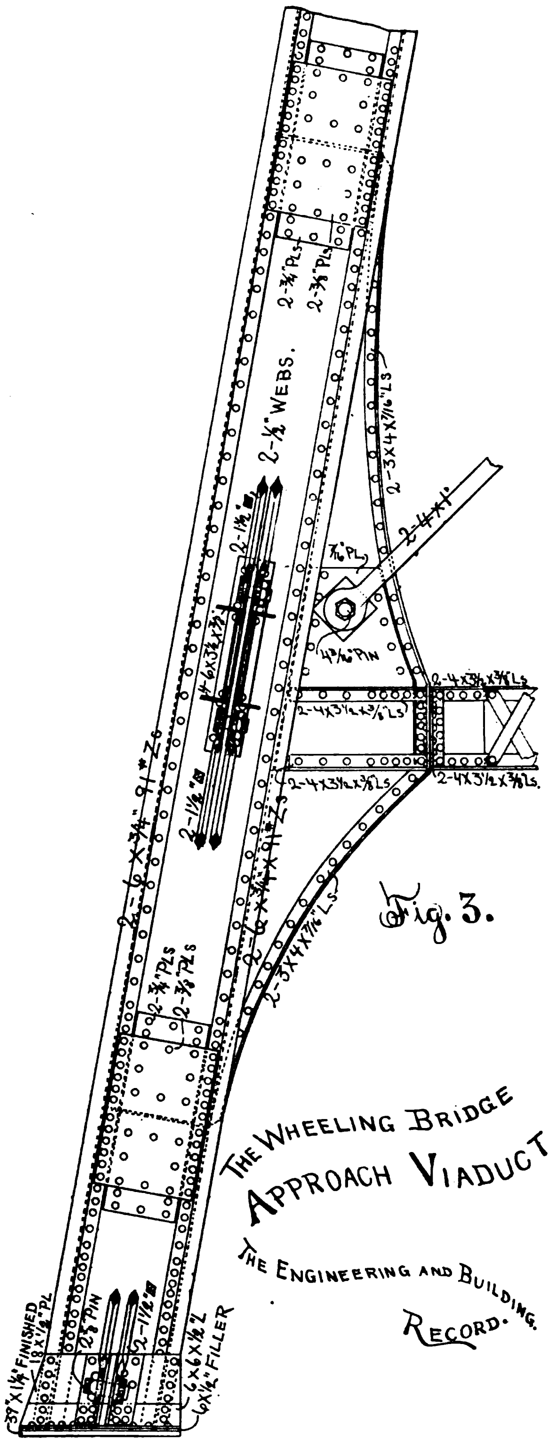
THE WHEELING BRIDGE APPROACH VIADUCT.

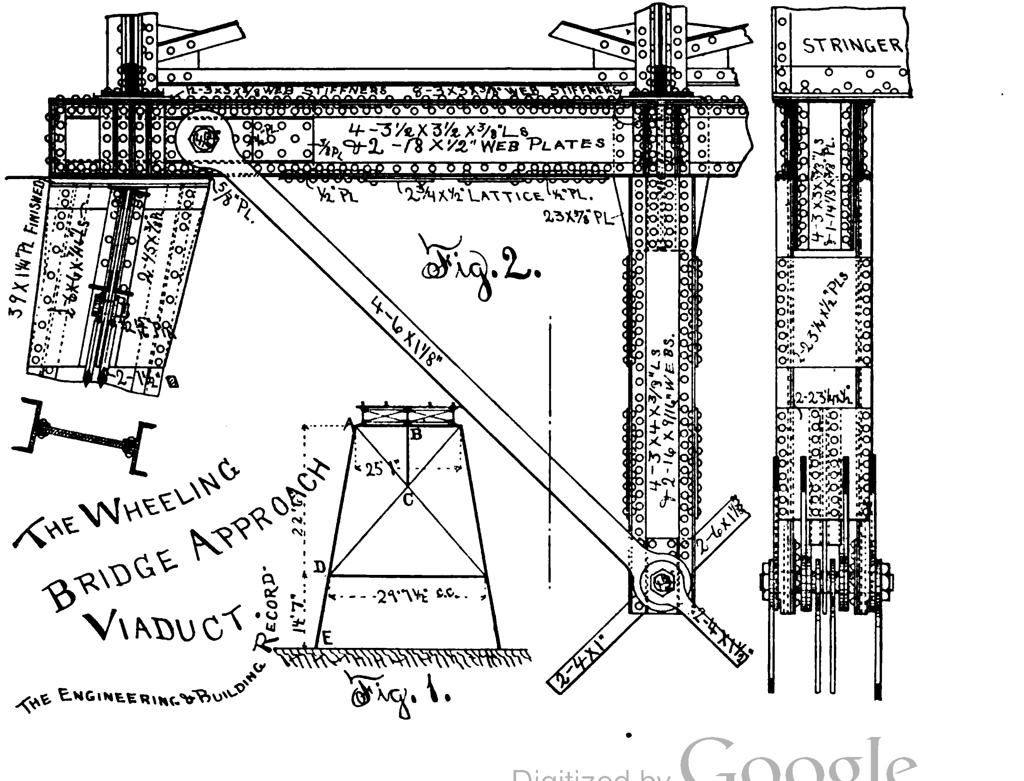
FIGURE 1 is a general cross-section diagram of the approach trestle viaduct of the new double track railroad bridge over the Ohio River at Wheeling, W. Va.

Figure 2 shows details of the connections at A B and C, Fig. 1, and Fig. 3 shows them at D and E. The special features of construction were designed to meet the requirements imposed by a 13-degree curve in the track, and the necessity of preserving clear headway for street traffic under the lowest transverse struts.

The viaduct is proportioned for a load of two 140-ton consolidation engines on each track, which is assumed to create a centrifugal force at 2 per cent. per degree of curvature. The tension members and pins are steel, the rest of the structure is iron.

Job Abbott, of New York City, is the Chief Engineer of the bridge, which is being built by the Edge Moor Bridge Company, of Wilmington, Del.





THE VICTORIA, B. C., SEWERAGE SYSTEM.

Mr. Rudolph Hering, in his recently submitted report on the most desirable system of sewerage for the city of Victoria, B. C., reviews the several plans which have been handed in for the work, and makes some valuable suggestions.

As to the disposal of the sewage, he points out that the first question to be considered is the way in which the sewage can be rendered harmless, after having been removed from the city. In the present instance, there is but one way practicable—viz.: A discharge into the Straits, where dilution in the large bodies of water will cause the sewage to disappear.

The many instances of sewage disposal have given an approximate measure of the least dilution which is found to be acceptable. For instance, in a running stream of fresh water in temperate climates, we try to have a flow of from 150 to 250 cubic feet of water per minute for every 1,000 inhabitants. If the water is cold and exposed to abundant aeration a smaller quantity will suffice. In salt water, on the other hand, a much greater dilution is necessary, mainly because the sewage water is much lighter, tending to spread out over the surface, and also because oxidation is less rapid.

When discharging sewage into any water except a running stream it is desirable to screen it before reaching the outlet. The large particles of floating matter are thus prevented from stranding at the shores by the action of the wind and waves. The quantity of matter retained by the screen will amount to perhaps a bucket full per day, but even this small quantity, in stranding and accumulating along the shores, might become objectionable. It can be disposed of with the garbage. In order to obtain the greatest possible dispersion of the sewage through the water the outlet should also be as deep below the surface as practicable.

Holding the above points in view, there are two localities where the sewage of Victoria can be safely discharged for some time. One is Clover Point, and the other Emily Island in Oak Bay. Soundings taken off Clover Point about 200 or 300 feet from shore, show a depth of water from 8 to 10 fathoms. There is a good current at this point during both tides, assuring sufficient dispersion of the sewage and rendering the quantity which can be economically delivered to it entirely unobjectionable. Mr. Hering, therefore, considers Clover Point as the proper outfall for the territory now requiring sewerage. To ascertain the actual degree of dispersion at flood and ebb tides, he recommends dumping several barrels of sawdust, previously well soaked in water, near the proposed point, and as far below the surface as practicable. It will be found to scatter over a large area; but, unlike sawdust, most of the suspended particles of sewage, when scattered in clear water will be consumed by fish and other aquatic animals. Discharging sewage merely into deep water does not guarantee against a nuisance, because, if the water is comparatively still, the sewage will rise and gradually permeate the entire body.

The next point to consider is the elevation at which the sewage can be discharged at Clover Point As it is not advantageous to allow back water in the sewers on account of deposits occurring at such times, and as no better discharge is secured by having the sewer below water, the available data led Mr. Hering to conclude that there should be a free discharge of sewage at the level of mean high water. The water rarely rises much above this height, and when it does, stays there but a few hours. Assuming that the outfall sewer at ordinary times will run one foot deep, the invert, or bottom of the sewer, can therefore be safely placed at one foot below mean high water. The sewage may be carried from the shore into deep water by a steel pipe, well coated to prevent corrosion, and well anchored to keep it in place. The chamber containing the screen should be placed below the last junction where sewage enters.

Owing to the necessity of giving sewage sufficient velocity to remove both the heavy and suspended matter carried along with it, the slope of a sewer is limited. With the lightest one that will answer, it is impracticable to carry all the sewage by gravity to the Clover Point outfall. A few locations are so low that their sewage will have to be pumped. If pumping were needed only in one locality, it would probably be most economical to use a gas or steam engine; but as in Mr. Hering's opinion it is needed in several localities, to avoid pollution of the harbor and the shores, the Shone Ejectors seem to offer the greatest advantage. They consist of a peculiar form of pump operated by compressed air, which is carried to them in a special pipe from a central station. Mr. Hering says that with good management these ejectors ought to give entire satisfaction. The conditions under which they are found to be economical rarely occur, because it is generally practicable to concentrate the sewage to a single locality. This is the only reason why they are not more used. As multiplication of machinery is always combined with more or less disadvantage, it is well, however, to have as few ejectors as possible, even at a greater first cost of the system.

As to the capacity of the sewers Mr. Hering says:

> "There has been some controversy in this city, I understand, as to whether the combined or separate system should be used, that is, whether the sewers should be large enough to take the rain water or not. This controversy, which was started in eastern cities years ago, mainly by parties interested in patented systems, is largely due to misapprehension. There are comparatively few cities in the world where all rain water is taken into the sewers, and still fewer where none at all is taken into them. The vast majority of systems are between these extremes while all cities need sewers for all of the sewage, the above character of the system is, therefore, decided by the quantity of rain water which can be allowed to run off over the surface. The larger the city, as a rule, the more inconvenience and damage is caused by surface removal. In most of the larger cities all, or nearly all, of the rain water is, therefore, taken into the sewers. In small cities the inconvenience and damages are less great, and the tax for the larger sewers is relatively heavier, resulting in the adoption of smaller sewers and in letting more rain water flow over the surface. As the city grows, supplementary sewers or drains for rain water are gradually built as needed. This gradual building of large drains is obviously a great advantage to younger cities which otherwise, on account of the expense, would often be debarred from the benefits of foul water sewerage for many years.
>
> "There is another advantage in not providing combined sewers in small cities. The streets are generally unpaved, and the rain water washes a large amount of mud and silt into the sewers in spite of all precautions. This unites with the sewage, and, in light grade sewers, causes it to deposit when it might otherwise flow off. This objection is greater in America than in Europe, because our streets, as a rule, are not kept in as good a condition as in the Old Country.
>
> "On the other hand, there is no reasonable objection to the removal of roof water through the foul water sewers. It is clean, and therefore helps to cleanse them as it reaches the main sewers simultaneously from the branches, it causes them to be flushed by every rain, and more thoroughly than can be done by automatic flushing or other artificial means. The house plumbing is often simplified and cheapened by letting the roof water enter the sewer pipe.
>
> "Again, the water falling upon roofs runs off without any loss by soakage, while that falling upon open ground or unpaved streets is much reduced in quantity when reaching the gutters. The removal of roof water, therefore, relieves the streets of a larger proportion of water than is commonly supposed, and postpones the day when drains for street water become necessary.
>
> "For these reasons it is usual in the smaller cities of England and in the United States to admit at least some water from the roofs into the sewers of the so-called 'separate' system. A difficulty seems to arise in ascertaining the proper quantity to be admitted; but this is overcome by restricting the roof water conductors above the ground so that a limited amount of water only will pass down to the sewer, and during very heavy rains the surplus flows out on the surface."

For Victoria Mr Hering finds the quantity of sewage to be very nearly equal to the water supply. Making an allowance for subsoil water, he thinks it safe to estimate for the present area of the city, the average quantity to be 15 cubic feet per day per inhabitant. Assuming that this area may eventually contain a population of 40,000 persons, the outfall sewer would have an average flow per day of 600,000 cubic feet. The maximum flow during the day is usually found to be 30 to 50 per cent. greater than the average. Assuming it, therefore, at the rate of 846,000 cubic feet, we obtain a maximum flow of sewage for 40,000 inhabitants of 10 cubic feet per section. It is of great advantage in several respects, particularly for keeping the sewers clean, to have the sewage not fill the sewer more than half full. At the exceptional times of flushing, or during rains, it can run full without harm.

Concerning the depth of the sewers below the street surface, Mr. Hering says that this is partly dependent upon the depth of the outfall and of those sewers which skirt the city and collect the sewage from the laterals. Besides the depths thus fixed by the plan, it is immaterial, from an engineering point of view, how deep they are placed, unless the cellars are dampened by ground water. Some cities have cellar drainage; others not. Some prefer to have it even at a large extra cost. In Victoria there should be deep drainage in the business districts, placing the sewers from 9 to 12 feet below the street. But the districts which will remain residential in the future, particularly on the higher grounds, a depth of from 3 to 6 feet will answer all the requirements. In some instances the main sewers are obliged to be very shallow in order to carry the water across a depression. The usual remedy for this is to raise the street at the depression. It is generally the cheapest and most satisfactory way of overcoming the inconvenience.

The estimated cost of the sewers for the entire city, according to the proposed plan, is $450,000.

A MILLION-DOLLAR SUIT DECIDED.

According to a Detroit, Mich., dispatch, dated August 2, a suit for $1,000,000 has just been decided there in favor of Cofrode & Saylor, Philadelphia, Pa., civil engineers and contractors, and against Brown, Howard & Co., New York City. In 1886, the latter received a contract to build 200 miles of a railroad between Duluth and Sault Ste. Marie, at $20,000 per mile with $500 per mile additional for accessories. Fifty-four miles were subsequently sublet to F. C. O'Reilly & Co., and 22 miles to Cofrode & Saylor, who began an action against Brown, Howard & Co., alleging that the specifications were not in accordance with the character of the country, the contract specifying hard pan where there was loose rock, together with other discrepancies. O'Reilly & Co., assigned their claims to the plaintiffs, and the suit embraced invalidity of contract regarding the building of 54 miles of road. The case was before the court 130 days, the testimony taken covered 8,000 type-written pages, and will cost the county $10,000. Don M. Dickinson, of Detroit, and J. A. Deady, of New York, were among the attorneys for the plaintiff, and ex-Governor Hoadley, of Ohio, and Ashley Pond, of Detroit, for the defence.

COST OF ELECTRIC POWER.

On the cost of power from electric motors the *Electrical Engineer* says: "It is to be borne in mind that the motor business depends largely for its success upon the rates at which the consumer can secure his current. We have received within the last few days the new schedule of power rates recently adopted by the Brush Company, of Baltimore, 'after a very careful consideration.' It is as follows: $\frac{1}{10}$-horse power, $2.50; $\frac{1}{4}$-horse power, $3; $\frac{1}{2}$-horse power, $5; 1-horse power, $10; 2-horse power, $16; 3-horse power, $21; 4-horse power, $26; 5 horse power, $30; 6-horse power, $33; 8-horse power, $42; 10-horse power, $50. This scale, which goes into effect on July 1, seems reasonable for a city presenting such conditions as Baltimore does, with a large population engaged in a variety of pursuits, but not distinctly of the industrial type, and not presenting so great a diversification of small industries as one finds, for example, in Boston or Newark. Still, the motor business has been fairly well worked up in Baltimore, and there are now 375 motors representing about 200-horse power of daily consumption of current. With the revised schedule this number and quantity should increase quickly."

STREET CAR LINES AT MADRID.

According to the Excerpt Minutes of the Proceedings of the British Institution of Civil Engineers, Madrid, notwithstanding the very uneven ground on which it is built, is traversed by tramways from one extremity to the other, with branches to most of the suburbs. The first line was constructed in 1871, from the fine suburb of Salamanca, which skirts the fashionable Prado, through the chief streets of the city, the Calle de Alcalá, and the central square, called the Puerta del Sol, to beyond the Royal Palace at the other extremity. The several routes are altogether 24 miles in extent, and for two-thirds of this distance the line is a double one. Terminal stations, coach houses, stables, and repairing shops have been built on a handsome scale, and the stock consists of 220 comfortable cars, and 1,396 mules and horses. Upwards of 1,000 men are employed in the service of the companies.

Electric drills are now being successfully used in connection with the work on board the monitor "Miantonomah" in the Brooklyn Navy Yard. A large amount of drilling must there be done around the turrets and in positions where the use of a power drill would entail considerable difficulty.

The city of Albany, N. Y., is going extensively into the asphalt paving experiment. The Albany *Evening Journal* says that taking contracts let and to be let they amount to a total of 128,000 square yards. The cost is estimated at nearly $400,000.

THE COVERED RESERVOIRS OF MONTMARTRE.

THE reservoirs which have just been built on the summit of Montmartre to supply water to the city of Paris are illustrated and described at length in a recent issue of *Le Genie Civil*, from which the accompanying cuts are reproduced.

The reservoirs occupy an area of 2,300 square meters, and consists of two distinct and entirely separate parts, one of them being two and the other three stories high. The first story of each reservoir has a storage capacity of 4,800 cubic meters and contains river water. The second story, of 4,200 cubic meters capacity, receives and distributes water direct from the source. The third story of the large reservoir holds also 2,000 cubic meters of spring water, and can be made to supply the old Chateau Reservoir, which has a capacity of only 150 cubic meters, and serves as a distributing reservoir for the higher sections of Montmartre. The whole quantity of 11,000 cubic meters of water is raised by works at the foot of the hill.

NEW COVERED RESERVOIRS • OF • MONTMARTRE

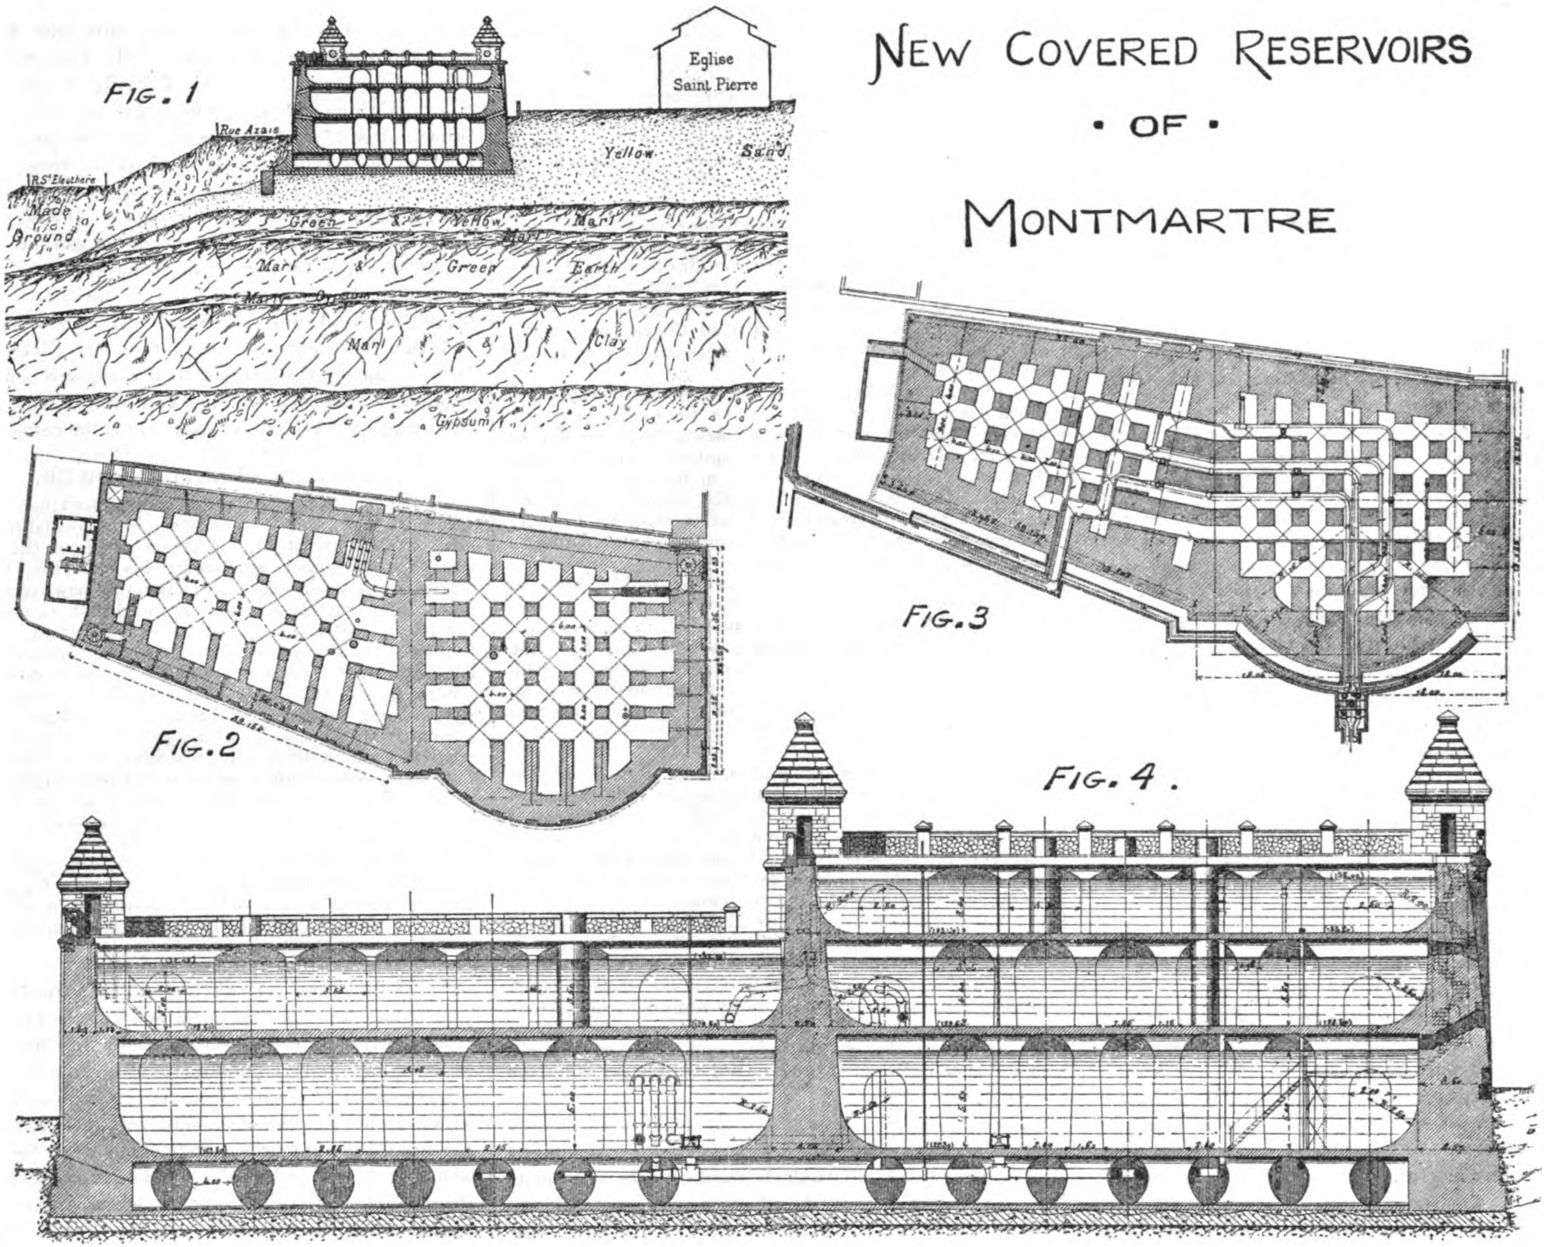


Figure 1 of the illustrations shows the geological formation below the reservoirs; Fig. 2 represents a horizontal section; Fig. 3 represents a horizontal section at the lowest story; Fig. 4 shows a vertical longitudinal section.

The geological formation encountered made the work of construction difficult in many respects and called for special precautions to prevent landslides. It will be seen from Fig. 1 that when once the virgin soil is reached a bank of yellow sand is found preceding the layers of gypsum, which are about 3 m. thick, very fine and easily carried away by water. It was necessary then to avert the considerable change which presents itself here, either from infiltration through the masonry or from the cracks, which are almost infallibly produced in the floors. With this in view, the principal floor has been made with a layer of concrete, covered over the whole extent with impenetrable cement mortar, leveled in such a manner as to form a series of trenches, at the bottom of which are the drainage pipes, all running into a small gallery, which forms a collector beyond the works. A second bed of concrete, the total thickness of which is 0.75 m., is run over the last covering, and finished horizontally to receive the masonry. The infiltrations are thus collected and drained off. This floor itself forms the ceiling of a lower chamber easily accessible, enabling the arch which supports it to be thoroughly inspected. The network of galleries, 2.40 m. in height and 2 m. wide at the springings, forms a series of supporting arches, the pillars of which are the bases of the pillars of the reservoirs. The floor of this lower chamber is cemented over where coming in contact with the arches and pillars, which are rough, in order to permit of the free flow of the water running through from the upper fissures. Finally, in order to prevent the escapes which would take place in the embanked part of the surrounding walls, and the existence of which might be unperceived for some time, one of the outer recesses of these walls has a covering with trenches, and drainage pipes running into the galleries of the under chamber. The lower story of the small reservoir, and the first two stories of the large one, are constructed in the center with supporting arches, and round the circumference with inverted arches, the outer walls being joined to the floor by inverts 2.50 m. in radius. The two upper stories are covered by means of elliptic brick arches, of a total thickness of 0.07 m., and a rise of 0.60 m., for 3.55 m. span; the abutment piers are isolated from the circumference walls, as also from the covering itself, by a space of 0.10 m., simply covered by brick placed flat without mortar. The spandrils of the arches are filled with concrete surmounted with a covering of cement and turfed over.

The following figures are here of interest:

	Meters.
(1) Great reservoir:	
Lower story: Depth of water	5
Depth under key-stone	5.80
Span of the vaults in center	2.70
Thickness of the pillars	(1.60 + 1.30) + 2
Middle story: Depth of water	3.50
Depth under key	4.40
Thickness of pillars	(1.15 + 0.95) + 2
Upper story: Depth of water	2.80
Depth under key	3.40
Thickness of brick pillars	0.45
(2) Small reservoir:	
Lower story: Same as lower story of great reservoir.	
Upper story: Depth of water	3.50
Depth under key	4.30

The surrounding and partition walls are calculated on the most unfavorable hypotheses, probably never realized in practice; all the stories reckoned as full, the isolation of the abutment piers of the arches of each story is assumed, and no account is taken of the support from the embankments, or of the counter thrust of the smaller reservoir for the partition wall.

The vertical pressures, on account of the oval form of the lower galleries, are uniformly divided over the whole surface of the foundation floor. For the small reservoir they are 12.03 k. and 1.70 k. At the base of the south wall there has been added an abutment apron (see Fig. 1) jutting out to prevent the removal of the bed soil there by underground water. The masonry is of millstone, with Portland cement and mortar, 470 kilos. per cubic meter of sand for the lower and middle stories, and of Burgogne bricks for the upper stories.

The decorative parts only are in rough ashlar facings, except the cornices and the covering of the towers, which are chisel dressed. The plasterings are of Vassy cement and sifted sand. The pillars of the upper stories are also uncovered, but they rest on the general coating of the corresponding floors. Lighting and ventilation are secured by lateral rectangular openings made in the outer walls. Light is admitted also through the top of the covering at one part, and through shafts, one meter in diameter, which give access to each story for handling material in case of repairs.

The first stories, as already remarked, are for the storage of river water. The supply pipe, 0.4 m. in diameter, first leads to a large tank from which two branches are carried to these first-story reservoirs. The supply pipe for the spring water also is 0-4 m. in diameter and leads to a supply tank for the second-story reservoirs. A branch with which this pipe is fitted permits of the filling of the upper story by cutting off the flow to the supply tank. Each story is provided with distributing and emptying sluices operated from the earthworks of the reservoirs.

The work was carried out between 1887 and 1889 under the direction of Mr. Bechmann, chief engineer, according to plans by Mr. Journat, supervised by Mr. Dutoit. The cost amounted to about 1,000,000 francs.

HOW CITY WATER MAY BE WASTED.

In the recently issued annual report of the Zanesville, O., water-works, the following table is published, giving, in gallons and hundredths of a gallon, the discharge of water per minute through various sizes of orifices at different heads. The table illustrates in a striking manner some of the points raised in the course of the water waste prevention discussion at the May meeting, at Chicago, of the American Water-Works Association. Rough calculations were there made tending to show the quantities of water which escaped in the small streams sometimes allowed to run from faucets in cold weather to prevent freezing.

In connection with the table it is explained that the wire of which pins are made is $\frac{1}{32}$ of an inch in diameter—No. 21 wire gauge. The finest cambric needle is made of wire $\frac{1}{64}$ of an inch in diameter—No. 27 wire gauge. A stream the size of a pin, running one year with head of 150 (being the average of low pressure in Zanesville) will flow 115,632 gallons, at a loss, counting at the rate of 10 cents per 1,000 gallons, of $11.57. A stream the size of a cambric needle, running at the same pressure for the same time, will waste 26,280 gallons, and, at 10 cents per 1,000 gallons, a loss of $2.63.

Gallons and Hundredths of Gallons that will be Discharged per Minute Through Various Sized Orifices at the Heads Stated.

Head in Feet.	Pressure per Sq. Inch.	DIAMETERS OF ORIFICES IN INCHES AND FRACTIONS OF AN INCH.													
		$\frac{1}{64}$	$\frac{1}{32}$	$\frac{1}{16}$	$\frac{1}{8}$	$\frac{1}{4}$	$\frac{3}{8}$	$\frac{1}{2}$	$\frac{5}{8}$	$\frac{3}{4}$	1	$1\frac{1}{4}$	$1\frac{1}{2}$	$1\frac{3}{4}$	2

DESIRABILITY OF CIRCULATION OF WATER IN RESERVOIRS.

In the course of a paper on "Algæ Growth in Reservoirs and Ponds," read before the New England Water-Works Association a few months ago, F. F. Forbes, Superintendent of the Brookline, Mass., Water-Works, said :

"In all reservoirs exposed to sunlight which are supplied from ground waters or from rapidly flowing streams, over rocky or sandy beds, circulation is a positive injury. Every gallon of such water contains food for millions of organisms, and each drop pumped into a reservoir increases the amount of organic matter to a corresponding extent.

"In proof of this, you have only to look again at the remarkable growths in the Brookline and Newton reservoirs. If a building was on fire, and to quench the flames a quantity of very combustible material should be thrown on it, it would not be difficult to foretell the result ; and there is no more reason in pumping into a reservoir a quantity of fresh water, with the idea in view of improving the quality of that water in so doing.

"As an additional proof of the statement I have just made, I will relate a little experience we had in the Brookline reservoirs several years ago. Everybody said that circulation was what we needed to keep the water free from algæ, and one time after the reservoir had been carefully cleaned, this view of the case was given a thorough trial. It was in summer, when our daily consumption was about a million gallons. All the water, nearly, was pumped into one end of the reservoir, and made to pass through it. The amount of water in the reservoir during this trial was not much in excess of the daily consumption ; in other words, nearly as much water was pumped into the reservoir each day, and drawn from it, as the reservoir contained, yet the algæ came in about the same length of time, and were fully as abundant. In consequence of this, the consumer received no water which was not laden with algæ ; whereas, if the water had been pumped directly into the distribution, and only the surplus reached the reservoir, the water would have been good as long as pumping continued.

"It is doubtful whether circulation improves water in any case, unless it is in ponds and reservoirs which have deposits of mud or decaying vegetable matter on the sides and bottoms, or water which has been drawn from such sources."

TAXATION OF PIPES IN PUBLIC STREETS.[*]

An interesting question of law, and one upon which the courts are in hopeless disagreement, arises when a tax is levied upon iron pipes laid by private parties in the public streets by permission of the local authorities. Common examples of such pipes are gas and water mains laid by private corporations.

The fundamental inquiry is as to the nature of the interest of the corporation in the mains after they have been laid. Four theories have been held by the courts.

I. In Tennessee it is held that the pipes remain the personal property of the company.[†]

II. In Iowa it is held that they are affixed to the land on which the main works or sources of supply are situated, and are taxable as real estate of the company in the town where that land lies, though they may run into another town.[‡]

III. In Rhode Island it is held that they are affixed to an easement which the company possesses in the soil of the street, and are therefore real estate of the company where they lie.[§] They are taxed, then, not *as an easement* of such value, but as actual tangible real estate owned by the company as appurtenant to its easement.

IV. In England it is held that they are affixed to the soil, and are, therefore, real estate ; but that they are only occupied, not owned, by the company.[‖] This view is apparently held in New York also.[¶]

To consider the less tenable views first, it seems clear that the theory of the Iowa court cannot be sustained ; though it is supported, it is said, by the practice of the assessors in at least one other Western State. It seems to have at least three fatal flaws. First, it is opposed to the facts. The water mains in that case were no more affixed to the water-works than to the street hydrants or to the land of consumers ; as, for instance, a bridge is equally affixed to each bank of the river. Secondly, it is opposed to every other decided case in which the subject is considered. Thirdly, it is opposed to common sense.

The Rhode Island case is based on a phrase of Lord Campbell in his decision in the Chelsea water-works case, so far as it is based on any authority ; and this phrase really lends no aid to the Rhode Island decision. It is a novel idea, that a chattel can be so affixed to an easement as to become the real property of the owner of the easement. If, for instance, the owner of a right of way should affix stone steps to the land, would they not pass to the owner of the land ? Could they be claimed as affixed to the right of way ? There are other objections to the Rhode Island theory, but this seems conclusive.

It remains to consider whether the pipes are personal property. It seems to me that they clearly are not, and that the English and New York theory is preferable to that of Tennessee. The pipes are put in the ground to remain there, or to be removed only when they become worn out and it is necessary to replace them with other pipes. Suppose the license of the company to use the streets were revoked, the company would clearly have no right, after that, to dig up its pipes. This is, to be sure, consistent with continued ownership by the company ; but intention settles the question whether or not they become part of the realty, and the fact that the company can remove its pipes only with the concurrence of the authorities is important, as indicating a probable intention that they shall remain in the soil.

In fact, when a worn out pipe is replaced by a new one, the old iron is carried away by the company. But this is consistent with theory that the pipe is part of the realty. Suppose a tenant chooses to repair a brick walk on the leased premises, putting in new bricks ; would he not be entitled to the old ones ? Could the landlord bring trover if he destroyed them ? Much more should it be so here. The company having a right to do so enters the land and severs certain old iron from the soil ; the iron becomes a new article of property, and may well go to the company.

Suppose, instead of laying pipes through the streets, a gas or water company should dig a tunnel, cementing the sides of it to prevent leakage. There can be no doubt that the cement would become part of the realty. Is there any difference when iron is used in place of cement for the same purpose? As iron pipe is it not *functus officio*, having become the wall of a tunnel, to be removed, if at all, not as iron pipe but as old junk?

This view, which is that of the English courts, seems to me the only one tenable. If it is correct, the remaining question is merely one of interpretation of the statute providing for taxation. It is in the power of the Legislature to tax the company for the pipes. This may be done, as in New York by a special provision making the pipes real estate of the company *for purposes of taxation*,[*] or as in Massachusetts, by taxing the value of the company's franchise, which is, of course, in an indirect way, taxation of the pipes, since the value of the franchise includes the value of the pipes.[†] An expedient holding gas pipes to be part of the machinery of manufacture[‡] is questionable in point of fact ; if in fact they were part of the machinery of the company they might well be taxed to it as such, though the legal ownership were in another.

In the absence, however, of a special provision of the statutes, pipes in the public street should be taxed neither as the real estate nor as the personal property of the company that lays them.

THE FOSTORIA, O., WATER-WORKS.

J. M. Howells, civil engineer, of Chicago, Ill., contributes the following particulars concerning the water-works now under construction at Fostoria, O., under his supervision.

Previous to his engagement the city had made numerous efforts to secure a water supply on the franchise plan. These resulted in letting the first franchise, about six years ago, to some New York people, who, after spending some money in boring wells, abandoned the enterprise. A year and a half ago another franchise was let, but this also was thrown up in little time.

Well water may be had in abundance, but is hard, running, in some instances, as high as 96 grains per gallon of soluble solids, which defy boiler compounds of every description. One of the railroads runs a water train, hauling water to the town daily for use in boilers. The impounding system has been adopted, taking the supply from 17 square miles of water-shed, which discharges floods through a small valley near the town, but furnishes no flow at all most of the season.

The works consist of a canal, taking water from the valley, a mile above the city. The canal discharges into a collecting and settling reservoir of about 15 acres water surface. This reservoir discharges through a brick conduit, three-quarters of a mile long, into a lower main reservoir of 20 acres water surface and 20½ feet deep, holding over a hundred million gallons. From the main reservoir water is conveyed to the center of a circular filter basin, where the daily supply is sprayed into the air by gravity, then sinks through the filter forming the bottom, and is conveyed to the well. The filter basin is six feet deep, underlaid by a filter-bed something after the old English plan. The water supply has been practically cleared of sediment by settling before arriving at the aeration fountain and filter-bed. Little is therefore left for the latter to do.

The water tower stands adjacent to the filter-bed and possesses some novel features. It is based upon the solid rock 25 feet below the surface; its first 16-foot section is the pump well, the next compartment above is the pump-room, the next above is a shop or water office and other storerooms above. At 53 feet above the surface, and 78 feet above solid rock, the masonry leaves off, and a steel water tank, 25 feet diameter by 100 feet high, commences. The pump-room is circular and 31 feet in diameter. Adjacent to the tower is a stone boiler-room 46x34 feet. The tower is being built of Berea and Grafton stone and superior class of masonry laid in Portland cement.

The pumps are two independent sets of duplex, horizontal, direct-acting pumps, to be furnished by the

Gordon Steam Pump Company, of Hamilton, O. The boilers are two of 85 horse-power each, furnished by the Mansfield Machine Works, of Mansfield, O. There are being laid 16 miles of cast-iron mains, from 14 to 4 inches. The pipe is furnished by the Lake Shore Foundry, and laid by J. J. Rumsey. By locating the works in town the force-main was eliminated, thus avoiding the use of 18-inch pipe, otherwise necessary. All the pipe system is productive, there being ten dwellings within a radius of 300 feet from the pumps.

H. J. Karg, of Fremont, O., is the contractor for the stone tower and boiler-house and filter basin, and the conduit, which connects the two large reservoirs. Cook & Heaton, of Junction City, Kan., are contractors for the reservoirs. The valves were purchased from the Rensselaer Manufacturing Company, and the hydrants from R. D. Wood & Co., of Philadelphia. The Porter Boiler Manufacturing Company, of South Chicago, are making the steel tank for the tower. All the work is progressing well, and will probably be finished before winter.

DATA ON BOILER SETTING.

AT the recent New York meeting of the American Boiler Manufacturers' Association, a partial report on boiler setting was submitted by a committee which had been previously appointed to take the subject in hand. The committee, as will be seen by the following synopsis, had prepared a series of questions which were sent to the members, but to which only three replies had been received. The questions cover the subject of boiler setting as far as it could be covered by the committee, and the statements sent to the several members requested that they would not only answer the questions presented to them, but that they would also send in such further questions bearing on the subject as might, in their judgment, seem of importance. The replies herewith presented were received from President James Laffan:

1. What do you consider the proper distance for boiler above the grate surface? and has this distance any fixed relation as to the area of the grate and the quality of fuel used? A. Distance from grate to underside of boiler 20 inches to 24 inches for coal. There is no relation between grate surface and this distance. For wood this distance should be not less than 28 inches to 32 inches.

2. What sized openings should the grate surface contain for different grades of fuel? A. The openings between grate bars should not be less than ⅜ nor more than ½ inch for coal. For wood and peat coal ¼ inch to ⅜ inch is wide enough.

3. What proportion should grate surface bear to heating surface for different grades of fuel? A. The grate surface should not be less than one-fortieth of the heating surface, but the larger the same is the better the result will be. For locomotive boiler the grate surface can be made somewhat smaller, but should not be less than one-sixtieth of the heating surface. Don't think there is any relation between heating surface, grate surface and fuel, the difference in fuel only requiring a difference in the grate openings. Do not think there exists any relation between length of boiler and length of furnace or grate under same. The length of grate should never be over 7 feet, as it is impossible to keep the same clear at the inner end.

4. What is the maximum length of grate that you would recommend for use without center rests? A. Five feet.

5. Have you had any experience with shaking grates? A. Yes, sir. Don't think very much of same, as they are very easily put out of order by pieces of cinders getting between the bars or into the shaking mechanism, thus causing breakage of bars and frequent repairs.

6. Have you had any experience with automatic stoking apparatus? A. No, sir. Think, however, that for some grades of fuel they are indispensable, such as coal, slag, sawdust, tan bark, and some sorts of peat coal, when they give a bright, clear fire, with little or no smoke.

7. Should air be introduced at the bridge wall? If so, state how. A. No. If the fuel is not put on the grate in too thick a layer no necessity for such introduction of air is needed. It is a fault met with everywhere; that whenever more steam is required the fireman fills up the grate with coal till it sometimes reaches the bottom of the boiler, thus frequently causing bagging of fire sheets, besides very heavy smoking of the stack.

8. Do you advise bridge wall to be straight or curved parallel to the boiler? A. Bridge wall to be straight. A curved wall has the tendency to concentrate flame and heat under center of boiler, as the flame will take the shortest way back to stack—*i. e.*, over the lowest part of the fire bridge.

9. What should be the thickness of bridge wall at top and bottom?

10. Should bridge wall be sloped or vertical? A. Bridge wall should not be less than 18 inches at bottom, but may be tapered off toward top to 9 or 13 inches. Do not think it makes any difference whether front of bridge wall is sloped or vertical.

11. Should the space behind the bridge wall be reduced or enlarged? State reason. A. Space behind bridge wall should be enlarged, as it will reduce the velocity of fire gases, and thus have them give up more of their heat to the boiler.

12. Do you think it advisable to take air in at any point back of bridge wall? A. No. The temperature of the gases is too low there to ignite any smoke that may have formed over grate. Hence it can have no other than a cooling effect.

13. In what place should fire brick be used; and in lining furnaces with fire brick should they be tied to the main walls or built independently, or do you prefer that the brick be laid in Flemish Bond? Should the joints be made thick or thin? A. Fire brick should be used in all parts of the setting which are exposed to the hot gases. It is better to have fire brick lining tied in with red brickwork, unless the lining is made 13½ inches thick, when it can be built up separate from outside walls. This arrangement will require very heavy walls. As usual out 9 inches fire brick lining is used in the fireplace and 4½ inches behind the bridge wall. Joints in fire brickwork should be as thin as possible.

14. What should be the depth of the ash-pit? And what rule would you follow in determining said depth? A. Depth of ash-pit is generally determined by local circumstances. Think it does not matter how deep or how shallow an ash pit is, as long as it is kept clean, so as to give the air necessary for combustion free access to the grate. A deep ash-pit has the advantage that it does not need cleaning so often. As a general rule the ash pit is level, or nearly so, with the floor on which the fireman stands, and as for convenient firing, the grate should not be higher than 28 to 30 inches; the depth of ash-pit is thereby determined.

15. Should the ash-pit be level or inclined? And do you approve of water under the grate? A. It makes no difference whatever whether the ash-pit is level or sloping from or towards the bridge wall. Water in the ash-pit may be of use on river steamers to reduce the danger of the woodwork taking fire. An advantage claimed for water in the ash-pit is: By the dropping of hot ashes and cinders from the grate into the water, steam is generated, which, in passing through the hot coal lying on the grate, is there divided into oxygen and hydrogen, thus helping the combustion.

16. Should the grate surface be level or inclined? A. Do not see any advantage in inclining grate bars, unless a so-called cinder grate is used, on which the cinders finally land, and which is so arranged that it can be dropped, thus throwing the accumulated clinkers into the ash-pit. An arrangement like this will reduce the labor of the fireman in cleaning grates considerably, and also prevents the introduction of cold air under the boilers while the fire doors are kept open during the latter process.

17. Should the boiler be set inclined or horizontal? A. Boiler should, as a rule, set horizontally, or nearly so. They may be set a little lower at the rear end, so as to facilitate the draining of the same.

18. What do you consider the best mode of suspending the boiler? (*a.*) Brackets on sides resting on walls? If so, should same be fitted with expansion rollers and plates? How many lugs do you recommend for each side of boiler? Also shape and location for greatest strength? (*b.*) Suspending from cross-beams above boiler by two hook rods on each beam from eyes or lugs on each side? (*c.*) Suspension from a center? (*d.*) Do you consider wooden beams in this connection a source of danger? A. Side brackets resting on masonry may be used for short boilers. If used on long boilers, side plates or expansion rollers should be used at one end of boiler. There ought to be not more than two brackets on one side, so divided that the distance between them is about three-fifths of the total length of the boiler, or the distance from ends of boiler to center of bracket is equal to one-fifth the length of boiler. Long and heavy boilers are best suspended from two beams or girders by two or three bolts at each end. Boilers over 40 feet long should have three or even four sets of hangers, as the case may require. Both hanger bolts being quite long and provided with heavy spiral springs, so as to make allowance for expansion and contraction. Wooden beams or girders used for supporting boilers are not necessarily dangerous if kept far enough away from masonry. In these days of iron and steel, wooden girders should not be recommended, however.

19. How should the tops of boilers be protected? Is there any objection to a plain brick arch? or, should there be an air space? or, should such space be filled with cinders? A. The tops of boilers are best protected by light cast-iron plates laid over the top of same and resting on the side wall. These can easily be removed so as to allow a frequent inspection of this part of the boiler. Brick arches, in case of a leak, have to be torn away and then rebuilt again. Cinders filling in between brickwork and boilers are dangerous unless granulated blast furnace cinder is used. Cinders from boiler or blacksmith's fire are very sulphurous and consequently have a high tendency to form rush, particularly where there is heat and dampness at the same time.

20 Do you approve of outside and inside wall for the boilers with an air space between? If so, state proper thickness of inside wall on side, outside wall on side, inside wall in rear, outside wall in rear, air space between side and rear wall, thickness of wall between two or more boilers, also proper air space for same. A. Where plenty of money and room is on hand boilers may be set with air spaces between the walls. No wall should be less than nine inches thick, with three or four inches air space between them. If boilers are supported by side walls, the outside walls should be 13 inches thick and have pilasters where the boiler is resting.

21. How should the walls be stayed? A. Unless boiler walls are very heavy, they should be stayed by cast or wrought iron buch-stays, held together by rods at tops and bottoms.

22. What is the proper distance from boiler to inside rear wall to admit accessibility to the tubes and proper area for currents of gases? A. The distance between the rear head of boiler and brickwork should not be less than 12 inches.

23. How should the back connection be made? With tee bars or by arching? A. Connections between rear end of boiler and brickwork is best made with cast-iron plates or fire brick, suspended, when boilers are suspended, as the expansion and contraction will destroy an arch in short time. If resting on mud-drum stand, this connection can be arched, as the rear end of boiler will remain stationary in this case.

24. Do you know of any reason why flues touching the boiler above the water space should not be emphatically condemned? A. No.

25. What do you consider the proper area for flue for single boiler? State what rule you would follow in determining this question. A. Do not understand this question.

26. Have you had any experience with automatic damper regulators? A. No.

27. Is it, in your opinion, dangerous to have large spaces in which gases may collect for sudden ignition, producing the so-called "back draught"? A. Yes.

28. In case two or more boilers are directed into the same flue, should any provision be made for diverting the draught for each individual boiler? A. If the draughts from the different boilers come in the same direction, or nearly so, no special provision of this kind is necessary, but if the draught enters from directly opposite directions a center wall should be provided.

29. Do you think it is good practice to use auxiliary pipes in furnaces or flues for heating water? A. No. unless they are so placed that they are easily accessible, as it happens quite frequently that these pipes choke up with scale.

30. State proper height and area of stack, and the method you would follow in determining same. Also state whether you would prefer octagonal or square brick stack, and how should it be lined? A. Area of stack to be not less than three-fifths of the total area of grate openings, and height not less than 40 feet; 100 feet is high enough for any boiler stack, provided the area is large enough for the work that is required of it.

31 What is the proportion of the area of the space over the bridge wall compared to the grate surface?

32. What should be the ratio of grate to tube area for the different grades of fuel for forced and natural draught?

In the discussion following the presentation of this report, Mr. Dunden, of San Francisco, stated that it referred only to one class of boiler—namely, cylinder-tubular boiler, and that this, in the opinion of the speaker, was the poorest boiler made. Mr. Raynal, a member of the committee, explained that the report was only a record of the doings of the committee, and that it was not intended to be final, and that it only partially covered the ground. The questions were sent out with the belief that the answers received would aid the committee in formulating correct rules for setting boilers.

Mr. Rohan stated that the report was supposed to cover externally fired boilers, and was not applicable to locomotive or marine boilers. It was not a report, but only a series of questions to be sent out and to really precede the presentation of a final and thorough report. The report was received and ordered printed.

BOOK NOTICES.

INTRODUCTION TO POOR'S MANUAL OF THE RAILROADS OF THE UNITED STATES FOR 1890; by H. V. & H. W. Poor, New York.

POOR'S Manual is so well known that even an outline of its character is not necessary to our readers. The pamphlet before us forms an introduction to the manual proper for 1890, and contains a series of carefully prepared tables, showing the general condition of the railroads of the United States in 1889, their mileage, equipment, liabilities, assets, etc. A few of the figures may be interesting here. The total number of miles of railroad in the United States at the close of 1889 was 161,397, of which 5,751 miles were built during the year. The cost per mile of all roads making returns, as measured by the amount of their stocks and indebtedness, equalled $60,309. In 1889 the total investment was $9,680,942,249; the gross earnings were $1,003,736,596, equal to 10.4 per cent. on the investment, and the net earnings were $332,284,986, or 3.3 per cent. on the capital.

AN important scheme for the development of the water power of St. Louis River, at Fond du Lac, Wis., is being carried through, all the rights and privileges of the St. Louis Water Power Company having been sold for $1,000,000 to a syndicate headed by the Wilburs, of Boston. Two dams will be built sufficient to command about 64,000 horse-power.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

PARTICULARS ON STREET CLEANING.

DEPARTMENT OF PUBLIC WORKS,
BUREAU OF STREET CLEANING,
PHILADELPHIA, JULY 8, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

Allow me to suggest that answers to the questions in the accompanying circular from the various towns and cities in this country would make interesting reading to many of your subscribers, as I find the subject of street cleaning is agitating the public mind to a very great extent at present.

I am frequently called upon by visitors from other places for information upon the subject, and as a reader of your paper I think it would be wise to get the information and arrange it so that one city could be heard from through each issue. Yours truly,

SYLVESTER H. MARTIN,
Chief of Bureau.

PHILADELPHIA

1. What is the population? A. 1,050,000.
2. How many houses, stores and dwellings? A. 203,500.
3. How often are ashes removed? A. Once each week.
4. How often is garbage removed? A. Three or four times each week.
5. How many miles of paved streets? A. 749 miles.
    - *a.* Cobble stones, 392.2 miles.
    - *b.* Rubble stones, 117.6 "
    - *c.* Granite block, 98.2 "
    - *d.* Macadam, 96 miles.
    - *e.* Asphalt block, 18.3 miles.
    - *f.* Asphalt sheet, 15.8 "
    - *g.* Brick, 11.2 miles.
6. How many miles of unpaved streets?
7. How often are they cleaned? A. Once, twice, three and six times weekly.
8. What is the average width of main streets? A. 50 feet.
9. Are your streets underdrained? A. Partially.
10. How many sewer catch basins? A. 7,600.
11. How often are they cleaned? Once each week.
12. What provision for removal of dead animals from the streets? A. Removed by street cleaning contractors.
13. Is the above work done by contract or by day's work? A. By contract, renewed each year.
14. What is the annual cost of cleaning the streets? A. Contract price, 1889, $425,042.
15. Does the city own the plant for street cleaning?
16. Does the city own the plant for removing ashes?
17. Does the city own the plant for removing garbage?
18. Does the city own the plant for cleaning catch basins?
19. Does the city own the plant for removal of dead animals?
20. For the supervision of all above work? A $11,920.
21. What is the final disposition of the street dirt? A. Used for filling low lands.
22. What is the final disposition of the ashes? A. Used for filling low lands.
23. What is the final disposition of the garbage? A. Fed to hogs, residuum used as fertilizer.
24. What is the final disposition of the dead animals? A. Buried.
25. Are streets swept by machinery or hand labor? A. Both.
26. What kind of hand-brooms are used? A. Bass, Push-brooms.

[In connection with what we have recently published concerning street-cleaning methods* the above will prove interesting. We have taken measures to collect further information on the subject in the way suggested by Mr. Martin, and will be glad to hear from anyone having data relating to it.]

A SYSTEM OF SIDE HILL STREET GRADES.

NEW YORK CITY, July 2, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: I have been much interested in the method of determining the proper elevation of corners in street intersections on steep grades proposed in the report of Messrs. Hering and Rosewater, to which attention was called editorially in your issue of June 28, and which certainly seems to be a very satisfactory solution of a very troublesome problem.

Among the suggested queries in your editorial is one regarding permissible grades on the diagonal at intersections. In the lower left hand corner of Fig. 3, page 53, the extreme difference of elevations between two curb corners is $11.26 - 8.74 = 2.52$ feet, and the distance between them is $42 \times \sqrt{2} = 59.4$ feet, giving a grade of $2.52 + 59.4 = 4.24$ per cent. It would be interesting to know if in Duluth this side grade ever gives any trouble to vehicles rounding the upper corner, or if it has been reduced by crowning, as you suggest.

Supposing the upper side of the same figure to be north, it will be noted that the southeast block corner of the northwest intersection is 0.66 feet lower than the curb immediately north of it, and as the southwest block corner of the northeast intersection would be only 0.3 foot above the curb facing it on the north side, it would follow that if the sidewalk grades at curb and blocks lines were uniform the latter would be lower than the former for more than two thirds of the length of the block, with the effect of running the rain water against the houses for that distance. Of course this is not done, on the contrary, Fig. 2, page 54, shows the lower sidewalk on side hill streets sloping toward the curb; but if any rule could be formulated to determine just how quickly or within what limits of distance or grade this reversal of the side slope of the sidewalks can well be accomplished it would certainly be desirable, and, in connection with what has been already given, would apparently enable the engineer to decide promptly and systematically every question that could arise concerning side hill street intersections.

In this connection I would like to suggest the following arrangement of street grades on a side hill in which, by throwing some of the inclination of the up and down streets into those at right angles with them, which might otherwise be level or nearly so, the maximum grades can be very much reduced and easy access be given to every part of the district.

For instance, in Fig. 1 is shown a set of street grades on a side hill whose average slope is 30 per cent. Here, by putting retaining walls, shown by short cross lines, across every other block of the up and down streets, as recommended in the Hering-Rosewater report, and undulating the grade of the cross streets, the maximum grades are reduced to 15 per cent., which is a practicable limit. By arranging the grades as shown in Fig. 2 the maximum may be reduced to 10 per cent., or a 45 per cent. slope may be traversed on 15 per cent. grades.

SIDE HILL STREET GRADES.

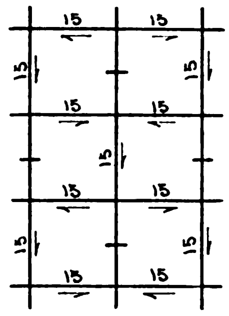

Fig 1.

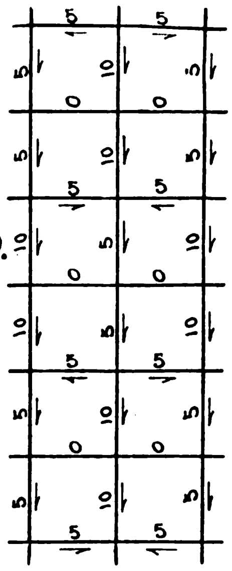

Fig 3.

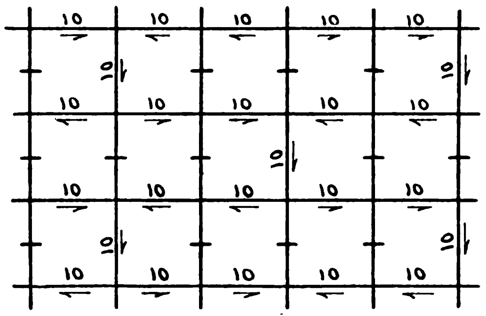

Fig 2.

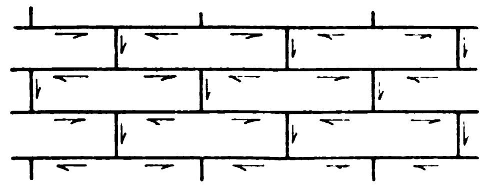

Fig 4.

If the arrangement shown in Fig. 1 is used on a 10 per cent. slope the cross walls might be omitted and the up and down streets would then have alternate grades of 5 and 15 per cent. while the cross streets would undulate 5 per cent. either way. Also, if the arrangement in Fig. 2 is used on a 15 per cent. slope all cross walls might be removed from every other up and down street, which would then have a uniform grade of 15 per cent. The other up and down streets would retain their cross walls on every other block with 5 per cent. grades between while the cross streets would undulate 5 per cent. either way.

For lighter slopes of say 7½ per cent. the arrangement might be modified, as shown in Fig. 3, where any part of the district can be reached within half a block on a 5 per cent. grade, the grade of the up and down streets alternating every two blocks from 5 to 10 per cent., while of the cross streets half of them undulate 5 per cent. either way and the other half are level.

The above typical illustrations are sufficient to show the general principle of the system which can be varied indefinitely to suit circumstances, and while irregularities of ground may seldom permit any single plan to be used for any great distance, the system will furnish a standard to be always approximated as closely as circumstances will permit.

It will be found that the best results are usually obtained by laying out the streets as nearly parallel and perpendicular to the contour lines as possible, except where the slope is light enough to permit uniform grades on an angle of 45 degrees with the contours, which will reduce the cut and fill.

In all the above figures the ground is supposed to rise from the observer and the blocks to be exactly square. The figures show the slope in feet per hundred while the half arrows point down hill. The amount of cuts and fills and hence the cost of the work will be reduced by making the blocks, or better, the distance between the cross streets (as distinguished from the up and down ones) as small as possible. This may in some cases lead to the arrangement shown in Fig. 4, in which no cross walls are used, and long narrow blocks like those in New York are substituted for the square ones with the alley through them that seem to be preferred in most western cities.

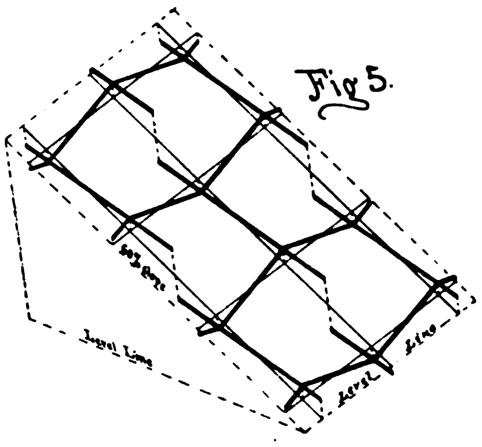

Fig 5.

Figure 5 is an isometric projection of the arrangement of grades shown in Fig. 1. The scale is the same, but in order to show the variations of slope more distinctly that of the side hill has been taken at 60 per cent., and that of the streets at 30 per cent. The centers of the streets are shown in heavy black lines, the breaks indicating the location of the retaining walls. The light lines are the projections on the side hill of the center lines of the streets and the distances between them and the heavy lines show the amount of cut and fill. The construction lines are dotted.

H. W. BRINCKERHOFF.

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

HOT-WATER RADIATORS ON A LEVEL WITH BOILER.

"ARCHITECT," of Cairo, Ill., writes: "Can a hot-water heater be set up as well on a level with the ground floor—that is, in the first story of a house as in the basement or cellar? Can it work to as good advantage in heating the first and second stories? In this town there are no cellars."

[In our issue of July 12, 1890, we show an arrangement of securing circulation through hot-water radiators placed below the level of the boiler. The flow pipe from the boiler is first carried up some distance, in this case to the top of the first story, and is then brought down to supply the radiators.

The plan has given entire satisfaction. The same method is frequently applied where indirect hot-water heating is employed, and where the indirect radiators are only slightly above the level of the top of the boiler. The working conditions of such radiators corresponds very nearly with those on "Architect's" first floor, the boiler and radiators there being on the same level. If our correspondent, therefore, will apply the principle illustrated in our former issue he will have no trouble in getting proper circulation in his first floor radiators. The second-story radiators call for no special considerations, and ought to work well when connected in the customary manner. We would suggest, however, that independent circuits be used for each story. With this arrangement each set of radiators will have its own main flow and return pipe, and there will be no opportunity for the upper radiators to circulate at the expense of the lower ones.]

---

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department.* Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

HOW MANY LEAKS ARE ALLOWED IN AMERICAN WATER MAINS?

W. Perry, Jr., hydraulic engineer, Montreal, P. Q., writes: "Would you, through your columns, ask the water-works engineers and superintendents of the United States if they allow seven leaks per mile in jointing cast-iron water pipe? My reason for asking you this question is, I saw a letter in one of our city papers saying that there was an average of four leaks per mile, and that the best American engineers allowed for seven leaks per mile. If such is the case it is the first time I ever heard of allowing for bad work in jointing water pipe. Water works men generally pride themselves in having as few leaks as possible."

[We quite agree with our correspondent that it would be a peculiar practice to make allowance for bad work in jointing water-pipe. One leak per mile ought to be sufficient to call for repairs.]

The contractors for paving Broadway and Park Row' New York, were notified on the 5th inst. by Public Works Commissioner Gilroy to begin the work on those thoroughfares within five days. The carrying out of these orders will make it necessary for the Broadway Railroad and the Third Avenue Railroad companies to make haste with their cable trenches. Unless the trench work is done before the new pavement is laid the Department of Public Works will oppose it. No permits can be secured for work that will necessitate the tearing up of a newly laid pavement.

In consequence of low water in the city reservoir at Amsterdam, N. Y., well water is being sold on the streets for five cents a pail. Many are afraid to drink the reservoir water because they think it impure. The water continues to recede, and just now there are said to be great fears of a water famine.

THE JOURNEYMEN PLUMBERS AND STEAM FITTERS.

The Journeymen Plumbers' and Steam Fitters' Association concluded its convention at Pittsburg on the 1st inst. The following officers were elected for the ensuing year: President, P. J. Quinlan, of Boston; First Vice-President, George McDonald, Denver, Col.; Second Vice-President, A. A. McLaughlin, Worcester, Mass.; Third Vice-President, M. J. Driscoll, Brooklyn; Fourth Vice-President, Thomas C. Shannahan, Pittsburg; Secretary, Richard A. O'Brien, Washington; Treasurer, P. H. Gleason, Brooklyn; Executive Board, representing Northern States, Edward Carroll, New York; M. J. Coolahan, Pittsburg; representing Western States, James H. Doyle, St. Paul; Charles H. Signor, St. Louis; Eastern States, James J. Doody, Brooklyn; J, Scott, Lowell, Mass.; Southern States, John M. Haupt, Baltimore.

In the matter of a uniformity of wages, it was decided that to form a national scale would be impossible, owing to the difference in prices of living in different localities. It was therefore agreed to elect a vice-president for each State, whose duty it would be to call conventions of delegates from the local unions in his State to regulate wages, apprentice laws, hours of work, and to confer with master plumbers as to the condition of the trade and consult with them as to means for improving it. It would be also the mission of the Board of Conference to arbitrate in the case of disputes and adopt such plans as would obviate, once and for all, all occasion for strikes.

The Vice-Presidents chosen for this work were: For New York State, Edward Carey; Colorado, M. J O'Garra; Massachusetts, A. A. McLaughlin; District of Columbia, N. J. Plast; Maryland, C. E. Zimmisch; Virginia, A. J. Bowman; Minnesota, J. F. Grillow; Nebraska, M. J. Conway; New Jersey, Thomas Hart; Connecticut, J. J. Flinn; Pennsylvania, James Robinson; Washington, D. H. DeClark; Missouri, William F. Coakley. The States not represented will be notified to send a name to the National Association to be appointed. The officers were installed and at 6 o'clock the convention adjourned. The next convention will be held in Denver, Col., on the last Monday in July, 1891.

USE OF LEAD TO PREVENT SLIPPERY PAVEMENTS.

Mr. J. C. Merriweather, of Greenwich, England, proposes a combination of lead with paving materials to prevent slipping. One plan is to place lead plugs or strips at or in the joints of paving blocks; preferably at the intersection of cross and longitudinal joints, and another is to use the same device in coalhole or manhole covers, the theory being that "lead is sluggish and bites."

It is a very difficult material for either a man or horse to slide on, but as heretofore used for wheelways, noticeably on Holborn Hill, London, it proved too soft to stand the traffic, while its value to the junk man proved a strain on the street Arabian under the trials of London life.

In coalhole and other covers in a sidewalk its use would be very grateful to pedestrians, while its employment in granite slabs might save a great deal of channeling now resorted to when they grow too slippery through wear for safety.

PLUMBING HEATING LIGHTING & VENTILATION
ENGINEERING

THE BENEFITS OF PLUMBING INSPECTION.

At the recent convention of the National Association of Master Plumbers at Denver, John J. Weaver, of Philadelphia, read a paper on plumbing inspection, in which he said that "one of the benefits is that inspection of plumbing and house drainage secures to the householder good plumbing; for, as the rules must be complied with the plumber must, therefore, be abreast with the times, for if he does not know how to work properly he must learn, or else quit the business.

"The inspection of plumbing and house drainage says to the householder: 'Stand by the department in seeing that the plumbers furnish a certificate of final inspection,' and they will find that the department is the means through which has been avoided the ventilation of the drain into the hot-air pipe of the heater, or the impregnation of the ground from leaky joints in soil pipes. It is presumed that in other places the same proportional beneficial results have followed the establishing of plumbing and house drainage as have been observed in Philadelphia.

"During the years, 1884, 1885 and 1886, the three years immediately preceding the establishment of house plumbing and house drainage in Philadelphia, the number of deaths from the principal zymotic disease was 8,897, and during the years 1887, 1888 and 1889, the three years immediately succeeding, the deaths from the above diseases were 8,401, showing a decrease of 436, a yearly average for the three years' life of the department of 165⅓.

"The householders are fast finding out that the conscientious, competent plumber does not deserve the abuse that so often has been heaped upon him by those who are ignorant of the amount of brains, as well as brawn, which is necessary to properly conduct the plumbing business, that the plumber is as important, if not more so, than the physician, for his work, if well done, prevents the diseases which, when once contracted, the physician cannot always cure.

"Now we must admit that whatever benefits the householder must benefit the plumber, for upon such customers he depends for prosperity in his business.

"The inspection of plumbing and drainage has been a powerful lever in raising the plumbing business to a higher standard, by showing the community that those who know how to do work properly were among the number active in establishing the inspection of plumbing and house drainage, having that commendable pride in their business which would not allow the death-rate of the city or town in which they lived to be increased through criminally defective plumbing, if such could be prevented by the inspection of their own work along with that of others who had no further interests in their trade than the amount of money to be made out of each job.

"The establishing of rules and regulations for inspection of plumbing by the Board of Health, or some other competent department, gives such a security to our customers that, where formerly they would have only crude and cheap fixtures, they now desire not only to increase the number of plumbing conveniences but to have them of elaborate and expensive material, all of which, of course, tends to the advantage of the plumber.

"Finally, inspection of plumbing and house drainage is increasing the number of plumbers who do good work, for no plumber can truthfully say that he alone in his city or town, where such inspection exists, is the only plumber who does good work. It increases the number of those who believe that good work pays, and have learned that their customers are willing to allow them a living profit for the same. In short, those who conceived and executed the thought of having plumbing and house drainage inspected by the Board of Health, or some other responsible authority in which the customers of the plumbers may have confidence, builded better than they knew."

A THEATRE FIRE PRESSURE SYSTEM.

The automatic steam and tank pressure arrangement for general and fire purposes in the Broadway Theatre, New York City, is shown in the accompanying diagram, where T is a 6,000-gallon iron roof tank, filled through a pump pipe A. B is an overflow. C is an emptying pipe. The general house supply is through a pipe D, which pierces the tank at E half way up, so that it can draw off the water in the upper half of the tank only, always leaving below the level E 3,000 gallons of water that can be drawn only through the fire line F, which has branches to four other lines, G G, etc. H is a check valve, closing by an upward pressure, I I, etc., are hose cocks. J is a Worthington pump with a patent automatic pressure regulator connected by a pipe K to the pump pipe F. Steam, at a pressure of about 60 pounds, is always kept up, received through the pipe L. A spring at N is regulated so that a pressure of about 70 pounds in the pipe will balance the steam pressure in the pipe L and close a valve at M. If, now, water be drawn from any hose cock I the pressure is diminished, the steam opens the valve M and starts the pump, whose pressure closes the check valve H and allows the pump to work at any pressure on the fire streams until the hose cocks are closed and the pressure in the pipe F becomes great enough to close the valve M. The tank water is thus shut off while the pump is working and so is preserved for use while the pump is starting if the street supply should fail.

THE ENGINEERING AND BUILDING RECORD

This arrangement is illustrated from a description by W. R. Bracken, of the firm of Moody & Bracken, of New York City, who did this work, with the other plumbing in the building.

HEATING AND VENTILATING SCHOOL-HOUSES.

(Continued from page 139.)

THE solution of the problems in school-house heating and ventilating, pointed out last week by Mr. William E. McClintock, has brought out some ingenious methods of conveying heat in, and foul air out, some of which are described by the author as follows :

SHURTLEFF SCHOOL, CHELSEA.

This is a three-story stone building with 16 rooms and a hall equal to two more rooms, and the coat rooms to correspond. The system in use in this building is what is known as the Smead & Northcott and includes the heating, ventilation and sanitation.

The building is divided into two equal parts, each being treated exactly alike. The fresh air is introduced through windows in the basement into chambers. Thence it passes into brick flues, and by means of a damper can be passed directly into the rooms, or first passed over the heater and then into the rooms, or part of it can go by each channel and be admitted to the room at any desired temperature by working the damper. The heater consists of a long fire-box protected by a corrugated iron lining that allows an air space between it and the casting of the box itself and which prevents the fire-pot being heated to a red heat. The flame and smoke pass out of the rear end of the fire-pot, then back through a series of tubes to the front end of furnace, when it again passes to the back end through a smoke pipe, and thence to the smoke flue. The air to be warmed thus comes in contact with a very large surface at a comparatively low temperature. The damper that allows the warm and cold air to mix is regulated by a crank in the school room and is worked at the will of the teacher alone The warm air is introduced into the rooms through a register in the wall about 8 feet above the floor, except in one or two cases where the construction of the building would not permit.

The foul air extractors are in the side walls at the floor on two or three sides of the room other than the side with the heat register. The extractors are in the aggregate a little larger than the inlet for warm air. These are 3-inch strips, fastened to the floor timbers and at right angles to same, that allow of a free circulation beneath the floors which are nailed to these strips. This last method has, I think, been abandoned at the present time on account of the extra danger of the rapid spread of fire. Vertical wooden flues, tin lined, pass down from each room, connecting with the space under the floors, and ending in a large brick gathering room.

From the gathering room the air passes into and through a tunnel that doubles on itself, and then by a right-angle turn, ends in the side of the bottom of the main stack, which is of brick and ends 4 feet above the roof. The inside dimensions of this stack are 3.55x5.62. A small heater in the stack at the cellar floor will heat the stack to a temperature of 92° Fahr., if desired, creating a current having a velocity of between 10 and 11 feet per second. An arrangement of closets and seats over the tunnel referred to furnishes a sanitary convenience. The fœcal matter is received on a brick floor so laid on iron as to give a 6-inch air space beneath it. On the boys' side the urinals discharge by pipes into the same tunnel. All of the moisture seems to be evaporated from both the fœcal matter and the urine, leaving a dry and almost inodorous substance which can be saturated with oil and be burned if so desired. The draught is at all times down through the seats when the covers are raised, with a velocity of from 6 to 10 feet per second. No smell can be perceived either in the closets or urinals, although some 800 or 900 pupils use them.

Air meter tests give a good flow of air under various conditions and in the direction planned and at rates that show the air in the room to be changed in from 9 to 16.4 minutes. The best results are when the stack is heated thoroughly and the air moves with a mean velocity of 5.5 feet per second. Allowing the school to be full, we have 450 pupils to each stack, and with 20 cubic feet per pupil, we have to discharge 9,000 cubic feet per minute, or at the rate of 5.5 feet per second. In order to get 30 cubic feet per second we must have a velocity in the stack of 8.5 feet per second.

A few tests have been made in this building to ascertain the amount of carbonic gas. These tests were made just before the noon closing, and showed at the breathing line 14.36 parts, and at the outlets 16.53 parts to the 10,000. This showing is rather a disappointment, but goes to prove that in order to get as low as 10 parts in 10,000 we must allow more than 20 cubic feet per minute. These results compare favorably with Prof. W. R. Nichols' examinations of 29 school rooms in Boston in 1880, when he got a mean of 15.6 parts per 10,000.

The cost of introducing the whole of the heating, ventilation, and sanitary appliances was $7.000.

BROADWAY SCHOOL.

This is a two-story wooden building with four rooms, each 28x32 feet, and 14 feet high. The building was originally heated by steam pipes running around three sides of each room, the steam being furnished by a tubular boiler. The ventilation consisted of an outlet flue; but no means were furnished to allow fresh air to come into the rooms.

There are 56 pupils in each room. The intention was to allow 25 cubic feet per minute per pupil when the building was remodeled in the year 1888. The steam pipes were left in their original position in order to act as supplementary heaters during very cold weather, and are intended to be used when the temperature is extremely low.

Steam coils are placed in the cellar, one each for a room, and these are connected directly with the outside air by flues having a clear opening of 30x18 inches, covered by a wire netting of ⅜-inch mesh. The flues allow the air to pass over the steam coil and thence into the school-room, being delivered into the room at a point about eight feet above the floor and on the side with no windows. The amount of air admitted through these flues can be regulated by means of a damper in each flue.

The foul air is removed by ducts built of lath and plaster work up to the attic floor, and from there the four ducts join together into one in the center, and near the roof have an inside measurement of 31 5x40.5 inches, or 8.86 square feet. The section of the ducts from each room is equal to 3.76 square feet. The main ventilating shaft ends just above the ridge of the roof in a cupola having wire netting around the openings to keep out the birds, etc. In the upper part of the main ventilating shaft there are six lines of 1¼-inch steam pipe passing around the four sides and heating the air of shaft. The flue for ventilation in each room has a register in the wall at the floor and one at the top of room. The lower register is the same size as the warm air flue, 30x18 inches, the upper one being slightly smaller, 18x10, for no other reason than that it was built so and not changed with the rest of work. The ventilating outlet is on the same side of room as warm air inlet. The expense of refitting this building as described was $450, which includes the indirect steam heaters, cold air boxes, flues for warm air to rooms, ventilating ducts from attic floor through the roof, and all the registers and fitting.

Several experiments have been made to see the amount of air passing into and through the rooms, and its quality in the rooms. Trials in the main shaft above the points of delivery for the individual flues gave as the rate for the whole building 16 8 cubic feet per minute per pupil.

There are two slight changes that could be made in this building that would probably add to the efficiency—viz.: The steam for the coil in the top of the main flue should come from a separate small heater or from the main boiler with shut offs for the other rooms ; as the rooms are heated too much when the outside temperature is high if more than two pounds are indicated on the gauge, while that amount will give good results in the shaft. The second change is to divide the cold-air shaft just before entering the coil box with a damper to allow the cold air to pass directly into the rooms or through the coil for heating or to be mixed to give any required temperature before entering the rooms. One other evil in this building results from the direct steam pipes in the rooms. These are often used by the janitor to heat the rooms in the morning quickly, but they are not always closed when the session opens. The result is too much heat ; and it is necessary to open the windows for comfort.

CARTER SCHOOL, CHELSEA.

This is a four-story brick building and as remodeled has what is known as the Fuller & Warren system of heating and ventilating. There are 16 rooms, a hall equal to two rooms, and the usual coat room.

The fresh air is introduced through galvanized iron boxes opening through the cellar wall, two at each end of the building, dividing the same into four equal parts. The air passes from the air boxes into the brick chamber where the heater is located, entering the same at the bottom. The heated air passes from the top of the heating chamber into brick flues that lead directly to the different rooms. The hot-air flues pass to the bottom of the furnace, where there are openings that allow the cold air to pass into the same and then into the rooms direct, if desired ; or where it can be mixed with the heated air to any desired temperature by means of a damper that is controlled by either the janitor, by a chain at the furnace, or by the teacher with a crank at the inlet register in the school-room. A double-acting damper closes the cold-air inlet before passing to the heater and at the same time opens the down extracting flue from the rooms, allowing the warmed air from these rooms to be heated over again during those times when school is not in session. This is no doubt a good thing as far as economy of fuel is concerned, but it is leaving a great deal to the honesty of the janitor ; or it affords a great temptation for him to be late about his fires in the morning if he so desires. Of course this damper should never be used when school is in session. The warm air is introduced into the room at a point about eight feet above the floor through the side wall, opposite the windows.

The foul air extractors are located in the floor or side walls at the floor, and are of tin-lined wooden construction and pass down to a brick chamber in the cellar below the concrete floor level from which point they pass into the base of the main stack, which is of brick, and passes up to a point about 4 feet above the roof. A small heater in the base of this stack, fired from the cellar, raises the temperature in the stack so as to give a good flow of air up the shaft and suction down from the rooms. The main stack has an area of 4x7 feet, and one is located at each side of building taking the air from eight rooms. Area of down extracting flues is about 640 square inches. The heater used here is a round furnace with tubes in the top to give an increased heating surface.

The State inspectors have got as high as 30 cubic feet per scholar per minute from all the rooms. At the only time I tried the discharge I found the air flowing through the stack at the rate of 11,620 cubic feet per minute, while 12,000 would allow 30 cubic feet per minute per pupil. Although I found this to be the mean flow I also found that in certain rooms we failed to get so good a result, the amount lessening somewhat as we reached the upper floors. Trials made since show this defect to be remedied mostly, if not wholly ; and it is safe to say that the pupils are getting the full 25 if not 30 cubic feet needed.

A test of the air in this building showed there were but 8.63 parts of carbonic acid gas at the breathing line and 9.08 parts at the outlet per 10,000. This result was obtained in a room on the second floor at 11.30 just as school was let out, but before the doors had been opened. The cost of putting in the heating and ventilating was $6,456.

I think I have said enough to show that there have been cases of badly ventilated buildings in which school children have had to work much to their disadvantage ; and that changes are taking place that are giving good results theoretically, and which will give to our children what is of far greater advantage than an education, and that is good health.

(To be continued)

COST OF ONE-INCH BRANCH TEE COILS.

THE Boynton Furnace Company, of New York, sends us the accompanying table giving the cost of 1-inch branch tee coils of various sizes. To steam and hot water fitters and engineers its convenience is at once apparent, giving as it does at a glance the area of heating surface in any size of coil, the cost of the complete coil, and the cost per square foot of heating surface. The table takes into consideration the cost of the pipe, right and left ells, branch tees, hook and expansion plates, plugs and wood brackets, and putting up, but does not include the cost of supply and return valves, air valves, nor the cost of connecting the coils with a distributing system after they have been made. The largest run of branch tees has been figured on, and the figures in general have been so taken that the prices given in the table may be considered as outside prices. Of course they will vary somewhat, according to locality and the ruling discounts on pipe and fittings, for which allowance must be made.

COST OF ONE-INCH BRANCH TEE COILS.

Discount on pipe from 1½ inches up, 55 per cent.; 1¼-inch pipe, down, 45 per cent. Discount on fittings, 70 per cent. Time, $6 per day for man and helper (10 hours per day).

Number of Hook Plates.	Length of Spring Pieces in ft. (lineal)	Height of Coils in Number of Pipes.	Length of Coils in ft. (lineal)	Time Required. Days.	Lineal Feet of Pipe in Coils.	Square Feet of Heating Surface.	Cost of Coil.	Cost Per Square Foot of Surface.
1	2	4	5	¼	28	9⅓	$5.90	63¼c.

THE largest cistern in the world is claimed to be under the machine shop at the Charlestown, Mass., Navy Yard. It is 100 feet in diameter, with a depth of 40 feet. It was built in 1858 by Master Laborer Otis Little, and supplied water to the great machine plant. The cistern was fed from a number of wells on the higher land near Chelsea Street by means of underground aqueducts. More than 850,000 bricks were used in its construction. This mammoth well has not been utilized since the introduction of Mystic water into Charlestown in 1865.

NEWARK, N. J., is considering the advisability of having electric wire subways. A short length of subway has been in use for over a year past, but subways are now proposed in a large number of streets.

STEAM-HEATING IN THE MECHANICS' BANK BUILDING, NEW YORK.

PART II.—THERMOSTATS, STEAM VALVES, ELECTRO PNEUMATIC VALVES AND DIRECT RADIATORS.*

ALL the heating in this building is automatically controlled by thermostats placed in each room, and operating pneumatic valves that regulate the admission of steam to the radiators and warm air to the conduits.

Figure 3 shows the details of the thermostat that may be set to work at any temperature, and is claimed to operate satisfactorily within a range of one degree. The figure shows the back of the instrument that is mounted on a brass bed-plate P, to which are fixed the standards A B B that carry the mechanism and have holes Z Z for attaching it to the wall or other convenient support. One end of lever C is connected to A by the pivot D, and the other end by a screw F tapped through lug E.

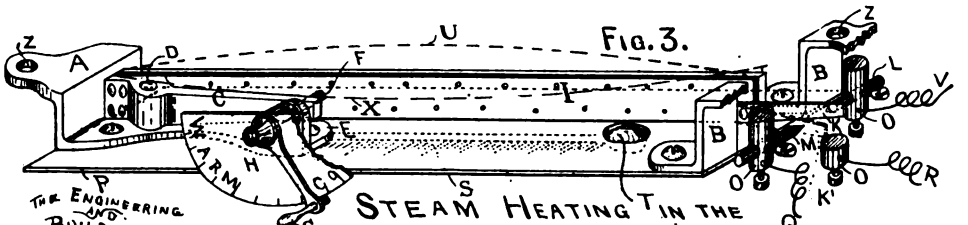

Fig. 3.

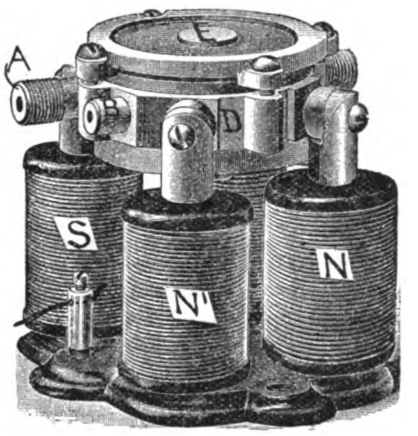
Steam Heating in the Mechanics Bank Building N.Y.



Steam Heating in the Mechanics Bank N.Y. Fig. 4.

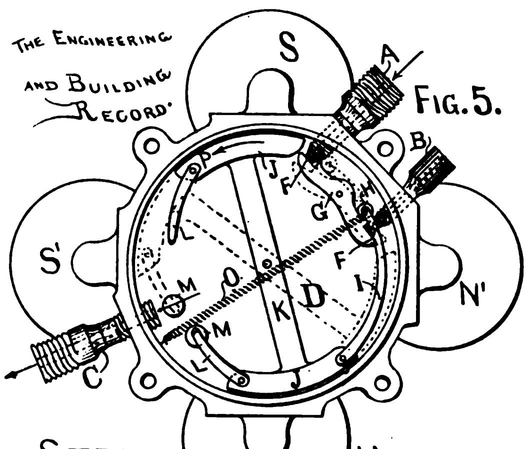


Fig. 5.

Steam Heating in the Mechanics Bank Building

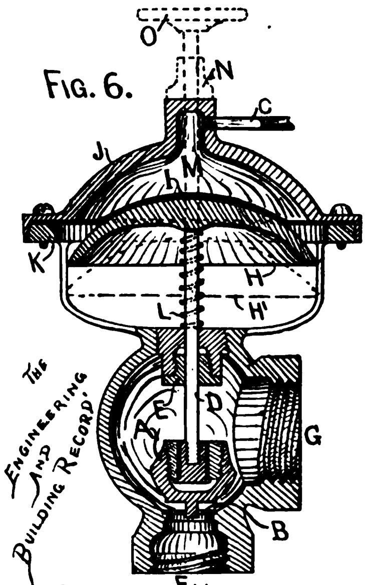

Fig. 6.

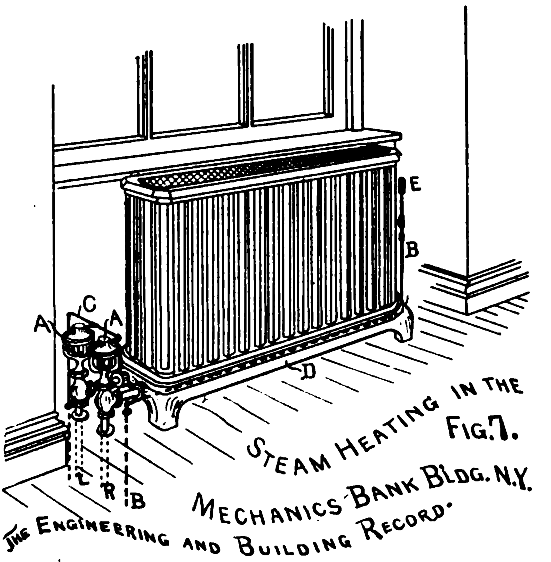
Steam Heating in the Mechanics Bank Building



Steam Heating in the Mechanics Bank Bldg. N.Y. Fig. 7.

The expansion bar I is made of a plate of brass and a plate of rubber riveted together and attached to lever C at pivot D.

The other end of the bar is free and carries a platinum contact bar K. O O O are bind posts fixed on plate B, and receiving the circuit wires Q R V, and the adjustable contact points L and M. The rubber and brass in bar I expand and contact differently for the same differences of temperature, so that a rise in temperature will make it bow out to the (exaggerated) position U, and throw K to K' in contact with M, thus completing the electric circuit from R through Q and opening the valve.

A fall in the temperature bows out I in the opposite direction to the (exaggerated) position X and makes contact between K and L, thus completing the circuit from R to V and closing the valve.

By moving lever G along the scale H, screw F is turned and swings lever C on its pivot D so as to set the bar K nearer to either L or M, and make the thermostat operate at any desired temperature within 15 degrees of that originally provided for.

T is a thermometer with scale S on the face of plate P, the thermometer is entirely independent of the thermostat and in no way connected with its operation, but is attached to it simply for convenience.

The current from the thermostat operates the electro pneumatic valve, of which Fig. 4 is a general view and Fig. 5 is a plan with the top E removed.

The chamber D is substantially a three-way valve with its ports opened and closed by a pair of electro magnets. A, C and B are tubes to the compressed air main, to the steam valve, and a free vent, respectively. C is always open into chamber D. A is open when B is closed and vice versa. N S and N' S' are electro magnets. J J are armatures connected by cross piece K that is pivoted in the center.

Lever G, pivoted at the center, has its faces F F covered with rubber into which the sharp edges of tubes A and B sink and make tight joints. The arm I is pivoted to one end of armature J, and carries the contact roller H that has its bearing on G maintained by the spiral spring O. The operation by the thermostat, Fig. 3, is as follows: Air pressure is always maintained in tube A, suppose it to be shut off as shown in Fig. 5, then the vent B is open and the steam valve operated through pipe C is open; if now the temperature rises a little and operates the thermostat it sends a current through V and magnatizes the poles N' S', which then attract the armatures J J that revolve in the direction P, and the movable parts of the mechanism take the positions shown by dotted lines; lever G opens A and closes B, and the pneumatic pressure in C closes the steam valve. When the temperature has fallen sufficiently the thermostat changes the current from V (Fig. 3) to Q, which correspondingly cuts it off from electro magnet N' S' and sends it through electro magnet N S, which then attracts the armatures J J back to the original position, shutting off air pressure through A, opening vent B and allowing the steam valve to open as pressure fails in C. L L are contact springs that switch off the current through conductors M M as soon as the armatures reach their extreme positions, thus cutting off the current and saving the battery.

Figure 6 is a sectional view of the steam valve and shows its operation by compressed air from tube C, Fig. 5. F is the steam inlet, and Q its outlet. B is the valve seat and A the poppet valve, whose stem passes through a stuffing box E and is fastened to a wooden head H.

I is a circular rubber diaphragm, clamped between the hemispherical shell J and the ring K. L is a spiral spring that opens the valve A as shown, when there is no pressure in chamber M; if pressure be admitted through C, the diaphragm and stem head will be forced down towards position H', indicated by dotted lines, and the valve will be closed and steam shut off as long as pressure is maintained in M. This cut shows the valves as used in this job, but in some cases the stem D is continued to pass through another stuffing box N and terminate in a handle O, shown by dotted lines, so as to admit of regulation by hand at the radiator independently of the thermostat system.

Globe valves, gate valves and other forms are also arranged in the same manner.

Figure 7 shows the arrangement of the valves illustrated by Fig. 6, on the Bundy radiators D, which are in most cases placed under the windows. L is the live and R the return steam pipe. A A the valves controlling their delivery, and C' is the air pressure pipe. E is the air valve, and B its vent pipe.

(To be continued.)

---

*Part I.—Arrangement of Exhaust Main, Boiler Feed Heater and Warming Fresh Air Blasts was published August 2.

TRADE PUBLICATIONS.

EXHAUST STEAM ECONOMIZER.

THE "Vacuum" exhaust steam economizer, made by Warren Webster & Co., of Philadelphia, Pa., is described and illustrated in detail in a new catalogue just issued, and dated July, 1890. A large number of testimonials from different sources are printed, tending to show that the apparatus is in extended use. As its name implies, the apparatus is designed to use exhaust steam economically in heating feed water for boilers and in acting as a purifier.

TUBULAR WELL SUPPLIES.

THE Cook Well Company, of St. Louis, Mo., have sent out a new catalogue in which they illustrate and describe their tubular well supplies and their system of tube wells. Strainers, pumps, hydraulic jacks and a large number of details are shown, and tables of sizes and prices are given.

STEAM AND WARM AIR HEATERS.

THE new catalogue recently issued by the J. F. Pease Furnace Company, of Syracuse, N. Y., gives detailed descriptions of their warm air furnaces and combination steam and warm air heaters. A large number of engravings are given, and also extensive tables of sizes.

THE MULFORD BOILER.

THE Mulford Heater Company, Galva, Ill., are sending out their new 1890 catalogue, in which their steam and hot-water heating boilers are illustrated and described at length. Interesting chapters also are given on steam and hot-water heating, the difference in cost between the two systems, fuel consumption, etc. The concluding pages contain directions for starting and managing the boiler, tables of prices and sizes, and numerous testimonials.

VALVES AND HYDRANTS.

THE Galvin Brothers' Valve and Hydrant Company, of Detroit, Mich., have issued a neat, new catalogue, devoted to their several water-works and steam specialties. A large number of different forms of gate valves for both water and steam corporation stop cocks and hydrants are illustrated and described, and sizes and prices are given.

The company are sending out also copies of a decree of the Circuit Court for Wayne County, rendered June 30, 1890, according to which their Mr. James Galvin is made sole owner of the contested patent on a swinging wedge gate valve.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

ARCHITECTURAL COMPETITION.

KENT, WASH. — Building. — Plans are wanted. no date specified, for erecting a $10,000 school building at this place. Address Clerk Board of Education, as above.

CONTRACTING INTELLIGENCE.

For works for which proposals are requested see also the "Proposal Columns,' pages i-ii-158.

WATER-WORKS WANTED.

CHESTER, N. Y., August 5, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

DEAR SIR: We have a scattering village here of perhaps from 700 to 1,000 inhabitants, and have been talking water-works for the past year. We have incorporated fire limits, but as yet have not been able to get water put in. Can you recommend me to any parties that would be likely to take hold and help put through a system of water supply if we can show good return for the investment.

GEORGE M. ROE.

IRON MOUNTAIN, MICH., Aug. 4, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

We have no paved streets, no system for cleaning, etc. We are about to get streets into shape and introduce sewerage and water supply systems.

F. E. WOODBURY,
City Engineer.

BUENA VISTA, VA., Aug. 6, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

The City of Buena Vista wishes to buy hook and ladder truck, hose wagon, and a number of 2½-inch linen rubber-lined fire hose. Address C. BARGAMIN,
Supt. City Water-Works.

WATER.

For Additional Water Items see Proposal Columns.

MURPHYSBORO, ILL.—M. T. Stookey, manager of the Belleville, Ill., Water-Works, is the contractor for the new Water-Works here and electric light plant. A stand-pipe has been contracted for, to be built by Riter & Conley. of Pittsburg, and a Hyatt filter will also be put in. The new works are almost completed.

ST. ALBANS, ME.—There is a project for a water-works system being discussed by the local officials.

MAMMOTH SPRINGS.—According to reports a stock company has been organized at this place for the purpose of establishing a system of water-works.

CLINTON, TENN.—It is about settled that this place will establish a water-works system.

BASTROP, TEXAS.—It is probable that the work of constructing the proposed water-works system for this place will be commenced before long.

GOLDENDALE, WASH.—The local officials have decided to establish a system of water-works at this place.

TRENTON, TENN.—Reports say that this city has voted $20,000 in bonds for the construction of water-works at once. Mayor M. Oppenheimer may be addressed.

GREENSBORO, ALA.—The people of this place have voted for water-works, and bonds will be issued at once. Mayor W. W. Powers can furnish information.

NORTH BROOKFIELD, MASS.—The people of this place are complaining of a shortage in the water supply, and there is a movement to increase it.

ST. LOUIS, MO.—Bids will soon be opened for the construction of six new settling basins by the Water-Works officials, to cost about $1,000,000.

FULTON, KY.—This city has decided to issue $25,000 for the purpose of providing for the erection of a system of water-works. Address the Mayor for particulars.

CORRECTIONVILLE, IOWA.—Reports say that this place is to have a system of water-works, and that the Town Clerk can furnish particulars,

ST. PAUL, MINN.—The Minnesota Subway Conduit Company has filed articles of incorporation with the Registrar of Deeds. The capital stock is $10,0000, and the project is to operate conduits and lay pipes conveying water from Lake Superior across Minnesota Point and Bay of Superior to the State line between Minnesota and Wisconsin. The following gentlemen are the incorporators: C. A. Severance, C. W. G. Withee, W. C. Hubbell, A. N. Taylor and S. Powers.

HUBBARD CITY, TEXAS.—The people of this place are discussing the water-works question.

DARBY, PA.—The Borough Council has passed a resolution granting permission to the Clifton Heights Water Company to lay pipes through the borough.

PHŒNIX, ARIZ.—The Farmers' Irrigation Co. has been incorporated here, with a capital stock of $100,000. A pumping outfit will be built.

SPOKANE FALLS, WASH.—Reports say that the Water Committee has recommended the construction of a reserve reservoir to guarantee better protection against fire.

MADISON, S. D.—H. Keene, Cashier First National Bank, writes: "The establishment of water-works has not progressed as rapidly as expected, owing to a delay made by the Artesian well contractors in not having their pipe on hand. The well is now down from 175 to 200 feet. No action has been taken by the committee in soliciting proposals for pipe and other material. It depends a good deal as to the result of obtaining a flowing or pumping well."

MONMOUTH, ILL.—There is talk of calling an election to decide the question of extending the water supply system at a cost of $25,000.

EAST PORTLAND, ORE,—A plant is to be established at this place by the East Side Water Company, at an estimated cost of $120,000. Address Isaiah Buckman for particulars.

BROWNSVILLE, TEXAS.—It is probable that a system of water-works will be established at this place. Particulars can be obtained by addressing Frank McMullen as above.

NEW BRITAIN, CONN.—The Committee on Water Supply has concluded that a new water main from Shuttle Meadow is necessary, and it is thought probable that the Water Commissioners will sanction its construction. The commissioners have recommended the building of a pumping station at the foot of Arch Street to serve as a temporary relief. Both matters will be considered at the next meeting of the Common Council.

NEW WESTMINSTER, B. C.—The following proposals for the construction of a system of water-works at this place were recently opened: E. S. Scoullar & Co., New Westminster, for material for main pipe, $41,954.28; for making and laying same, $113,161.40; total, $155,115.68. Wolff & Zwicker, Portland, Ore., for material, and making and laying main pipe, $171,271.60. D. McGillvray, Vancouver, for material for main pipe, $45,589.45; for making and laying same, $104,476 80; total, $150,066.25. Albion Iron Works Company, Victoria, for material for main pipe, $55,522.63; for making and laying same, $107,714.50; total, $163,237.13. The Risdon Iron and Locomotive Works, San Francisco, for making and laying the main pipe, $115,586. Bell-Irving, Patterson & Co., New Westminster, for material for main pipe, $41,954.28. J. J. Robson, London, England, for material for main pipe, $42,929. Contract let to D. McGillvray.

SHELTON, WASH.—W. D. Baldwin, Town Clerk here, writes: "The town of Shelton is about bonding itself for $20,000 for the purpose of erecting and maintaining water-works, electric lights, and for street improvements."

LEBANON, PA.—Press dispatches say that there are serious fears of a water famine at this place, and that steps will probably be taken to increase the supply.

FALL RIVER, MASS.—Reports say that the Board of Aldermen has voted to borrow $25,000, the money to be used for the extension of the water service.

LOWELL, MASS.—Numerous water-main extensions are to be made at this place.

SOUTH BEND, IND.—The question of making extensive improvements to the water-works system at this place is being considered by the city officials.

CHICOPEE, MASS.—Extensions are soon to be made to the plant of the local water company.

ST. PAUL, MINN.—The Board of Public Works will consider plans for a new pump at the McCarron Lake station.

MILES CITY, MONT.—S. Gorden, City Clerk, writes: "The Miles City Water and Electric Light Company, of which E. R. Gilman, President of the North-West-Thomson-Houston Electric Company of St. Paul, is President; and H. F. Batchelor, President of the Stockgrowers' National Bank of Miles City, is Secretary and Treasurer, have just completed a limited water supply for Miles City, Mont. At present only about 1¼ miles of mains have been laid for the protection of the business portion of the city, but the indications are that the system will be rapidly extended. The supply is from drive wells, 20 2-inch wells supplying a large pump and 5 supplying a small pump."

WEBSTER, MASS.—It is probable that the movement for water-works at this place will result in establishing a system at an estimated outlay of $75,000.

SPRINGFIELD, MASS.—The bids received by the Water Commissioners for the work of improving Ludlow reservoir, were not satisfactory, and probably new bids will be called for.

NORTH BROOKFIELD, MASS.—Town Clerk George R. Hamant writes: "Private citizens have made preliminary surveys for water. The town has not taken any action yet. The Board of Trade is to make some investigations relative to obtaining water, then, probably, the subject will be brought before the town."

NEWARK, N. J.—The Executive Committee of the Aqueduct Board has recommended that proposals be advertised for furnishing 12,300 feet of 24-inch pipe and specials; also 1,800 feet of 12-inch pipe and specials, for the purpose of laying a new distributing main from the Clinton Avenue reservoir to Walnut Street, in accordance with plans already submitted to the Board: also, for furnishing the pipe and specials and laying the same.

LANCASTER, PA.—An additional reservoir is proposed for this city at a cost of about $27,000. For particulars, address Robert Clark, Chairman Water Committee, as above.

LEEDS, IOWA.—This place is to have a system of water-works.

PETALUMA, CAL.—Extensive improvements are to be made to the plant of the Petaluma Water Company.

ALEXANDRIA, LA.—It is probable that the projected water-works system for this place will soon be established.

ASTORIA, ORE.—The sum of $150,000 is to be expended on improving the local water-works system.

JANESVILLE, WIS.—The Board of Water-Works Directors of this city has ordered the laying of an additional 4,500 feet of mains.

WATER-WORKS.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Marysville, O.; Pasco, Wash.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

ST. PAUL, MINN.—The Board of Public Works will recommend the appropriation of nearly double the amount of money for sewers this year that they did last year. The amount of paving done will be somewhat less, and that of other improvements will be about the same.

CENTRAL FALLS, R. I.—Frederick E. Shaw, of this place, has been awarded a contract to construct new sewers, at a cost of $10,000.

OTTAWA, CAN.—It is proposed to drain Stewarton and Rochesterville, at an estimated cost of $200,000. The City Engineer can furnish particulars.

CINCINNATI, O.—A trunk sewer 12 foot connection, 1,000 feet long, will be ready for bidders at the City Engineer's office in ten days.

WILLIAMSPORT, PA.—It is probable that important steps will soon be taken towards making the proposed improvements to the sewerage system of this city.

WEST TORONTO JUNCTION, ONT.—Willis Chipman, C. E., Toronto, Ont., has made a report on a proposed system of sewerage for this town.

HARRISON, N. J. — Considerable sewer work is contemplated at this place. For particulars address the Clerk of the Common Council, as above.

MERIDIAN, MISS.—Reports say that a system of sewerage is to be established at this place.

SEWERS.—See our Proposal Columns for information regarding sewer construction at the following places: Boston, Mass.; Tiffin, O.; Binghamton, N. Y.; Galion, O.; Greensboro, N. C.; Cleveland, O.; Key West, Fla.; Para, Brazil.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

TOPEKA, KAN.—At a recent election in Shawnee County it was voted to appropriate $200,000 for building a bridge across the Kansas River at this place. The bridge will have a 50-foot roadway.

WILLIAMANSETT, MASS. — The County Commissioners are having plans prepared for the masonry and superstructure for a new iron bridge across the Connecticut River between Holyoke and this place.

MINNEAPOLIS, MINN.—The Great Northern road is preparing to build a bridge over its tracks at Fifteenth Avenue S. E., as ordered by the City Council some time ago. Plans have been prepared, and the work will begin soon.

LITTLE ROCK, ARK.—Reports say that a bridge will be probably be built over the Arkansas River from this city to Argenta.

ROCHESTER, N. Y.—Reports say that a new bridge is to be erected at Court Street, at an estimated cost of $150,000.

CINCINNATI, O.—The plans prepared by the City Engineer for the Eight Street viaduct provide for a structure 2,956 feet long, which it is estimated will cost $280,000. It is also proposed to rebuild the McMillan Street bridge at an expense of about $35,000.

LYONS, IOWA.—The contract for the construction of a bridge over the Mississippi River at this place, has been awarded to the Chicago Bridge and Iron Company, at $90,990.

WESTON, W. VA.—The Suars County Commissioners have accepted plans for a new iron bridge at Weston. The Commissioners will soon advertise for proposals.

DODDRIDGE COUNTY, W. VA.—The County Court of this county has ordered its Committee on Roads to advertise for proposals for four steel bridges for this county.

ALEXANDRIA, LA.—A new bridge is to be erected over the Red River near this place.

FALL RIVER, MASS.—It is proposed to erect a bridge over the tracks of the Old Colony Railroad, at South Park.

NEW BRUNSWICK, N. J.—The Board of Freeholders of Middlesex County, at a recent meeting, authorized the erection of a large number of new bridges and culverts. Among them were several culverts over the Commercial Avenue brook in New Brunswick.

BRIDGES.—See our Proposal Columns for information regarding bridge construction at the following places: Trenton, N. J; Whitby, Ont.; Toledo, Wash.; Montgomery, Ala.; Beeville, Tex.; Hamilton County, O.; Brooklyn, N. Y.; Newport, R. I.

STREET-WORK AND PAVING.

ST. PAUL, MINN.—A proposition has been brought before the Board of Public Works to pave Bradley and other streets in the vicinity. It will come up again for consideration on August 16. The estimated cost of the paving is $52,000.

EAST ST. LOUIS, ILL.—The Highway Commissioners of Centerville Station Township have contracted with Caster Stalle, of this city, for the paving of Cahokia, Caseyville, Collinsville and Centerville roads.
